Conclusions: Rifaximin therapy for 2 wk provided significant relief of symptoms, bloating, abdominal pain, and stool consistency associated with IBS without constipation.

Prognosis
- 80% improve over time
- most have intermittent episodes
- normal life expectancy

Constipation

Definition
- passage of infrequent/hard stools and/or difficult stool evacuation (e.g. straining, sensation of anorectal blockage)

Epidemiology
- increasing prevalence with age; F>M
- rare in Africa and India where stool weight is 3-4x greater than in Western countries

Etiology
- most common: functional, idiopathic attributed to colon dysmotility but this is difficult to measure
- organic causes: likely only if there are symptoms other than constipation
  - medication side effects (e.g. narcotics, antidepressants) are the most common

Causes of Constipation

DOPED
Drugs
Obstruction
Pain
Endocrine dysfunction
Depression

- intestinal obstruction, left sided colon cancer (consider in older patients), and fecal impaction
- metabolic
  - DM
  - hypothyroidism
  - hypercalcemia, hypokalemia, uremia
- neurologic
  - intestinal pseudo-obstruction
  - Parkinson's disease
  - MS
- collagen vascular disease (e.g. scleroderma)
- painful anal conditions (e.g. fissures)

Clinical Features
- overlaps with IBS with constipation (IBS-C) but labeled as IBS-C when pain is a predominant feature
- stool firm, difficult to expel, passed with straining, abdominal pain relieved by defecation, flatulence, overflow diarrhea, tenesmus, abdominal distension, infrequent BMs (<3/wk)

Investigations
- underlying disease rarely found if constipation is the only presenting symptom
  - only test indicated in this situation is a CBC (2013 recommendation of American Gastroenterology Association), but also consider TSH, calcium, glucose, and abdominal x-ray
- colon visualization (colonoscopy, CT colonography) if concomitant symptoms such as rectal bleeding, weight loss, anemia or age >50
- if refractory to treatment, consider classification based on colon transit time; can measure colonic transit time with radio-opaque (Sitz) markers that are ingested and followed with a series of plain film abdominal x-rays (normal: elimination of markers within 70 h)
  1. normal = misperception of normal defecation (IBS)
  2. prolonged throughout = "colonic inertia" (infrequent bowel movements with gas/bloating, tends to occur in youth)
  3. outlet obstruction = inability to coordinate pelvic floor muscles to empty rectum, straining, stool in rectum on digital exam, tends to occur in old age
- combination of 1 and 3 common

Treatment (in order of increasing potency)
- dietary fibre
  - useful if mild or moderate constipation, but not if severe
  - aim for 30 g daily, increase dose slowly
- surface-acting (soften and lubricate)
  - docusate salts (likely limited efficacy based on evidence), mineral oils
- osmotic agents (effective in 2-3 d)
  - polyethylene glycol 3350, lactulose, sorbitol, magnesium salts (e.g. magnesium hydroxide, i.e. milk of magnesia), lactitol (β-galactosido-sorbitol)
- cathartics/stimulants (effective in 24 h)
  - senna, bisacodyl
- enemas and suppositories (e.g. saline enema, phosphate enema, glycerin suppository, bisacodyl suppository)
- prokinetic agents (e.g. prucalopride, HT4 inhibitor)
- secretagogues: linaclotide, plecanatide (increases water secretion into the intestinal lumen)
- NHE3 (sodium-proton) inhibitors: tenapanor

Upper Gastrointestinal Bleeding

Definition
- bleeding proximal to the ligament of Treitz, see *Overview of Gastrointestinal Tract, G2* (75% of GI bleeds)
  - ligament of Treitz: suspensory ligament where fourth portion of the duodenum transitions to jejunum

Etiology
- above the GE junction
  - epistaxis
  - esophageal varices (10-30%)
  - esophagitis
  - esophageal cancer
  - Mallory-Weiss tear (10%)
- stomach
  - gastric ulcer (20%) (see *Peptic Ulcer Disease, G11*)
  - erosive gastritis (e.g. from EtOH or post-surgery) (20%)
  - gastric cancer
  - gastric antral vascular ectasia (rare, associated with cirrhosis and connective tissue disease)
  - Dieulafoy's lesion (very rare)
- duodenum
  - ulcer in bulb (25%)
  - aortoenteric fistula: usually only if previous aortic graft (see sidebar)

Always ask about NSAID/Aspirin® or anticoagulant therapy in GI bleed

Aortoenteric Fistula is a rare and lethal cause of GI bleed, most common in patients with a history of aortic graft surgery. Therefore, perform emergency endoscopy if suspected, emergency surgery if diagnosed
Note: The window of opportunity is narrow. Suspect if history of aortic graft, abdominal pain associated with bleeding

Transfusion Strategies for Acute Upper Gastrointestinal Bleeding
NEJM 2013;368:11-21
Study: Prospective, unblinded, RCT, follow-up up to 45 d.
Population: 921 patients with hematemesis, bloody nasogastric aspirate, melena, or both. Exclusion criteria included massive bleed, acute coronary syndrome, stroke/ transient ischemic attack or transfusion within previous 90 d; recent trauma/ surgery; lower GI bleed.
Intervention: Patients randomized to restrictive (<70 g/L) or liberal (<90 g/L) transfusion.
Outcome: Mortality, further bleeding, adverse events.
Results: Fewer patients in the restrictive group required transfusion (51% vs. 15%; P <0.001). The hazard ratio for death for restrictive compared to liberal transfusion was 0.55; 95% CI 0.33-0.92; P=0.02. Further bleeding occurred in 10% vs. 16% (P=0.01) of patients, while adverse effects occurred in 40% vs. 48% (P=0.02) of patients in the restrictive and liberal strategies, respectively. The restrictive strategy had a better survival rate in patients with bleeding associated with cirrhosis Child-Pugh class A or B (HR: 0.30; 95% CI 0.11-0.85), but not in cirrhosis Child-Pugh class C (HR: 1.04; 95% CI 0.45-2.37) or a peptic ulcer (HR: 0.70; 95% CI 0.26-1.25).
Conclusions: Transfusing patients with an acute UGIB at Hb of <70 g/L rather than 90 g/L is associated with fewer transfusions, better survival, and fewer adverse events.

- coagulopathy (drugs, renal disease, liver disease)
- vascular malformation (Dieulafoy's lesion, arteriovenous malformation)

Clinical Features
- in order of decreasing severity of the bleed: hematochezia (brisk UGIB) > hematemesis > melena > coffee ground emesis > occult blood in stool

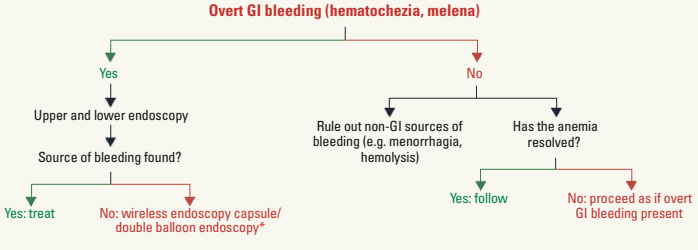
Treatment
- stabilize patient (1-2 large bore IVs, IV fluids, monitor)
- send blood for CBC, cross and type, platelets, PT, PTT, electrolytes, BUN, Cr, LFTs
- keep NPO
- consider nasogastric (NG) tube to determine upper vs. lower GI bleeding in some cases
- IV PPI: decrease risk of rebleed if endoscopic predictors of rebleeding seen (see prognosis section)
  - given to stabilize clot, not to accelerate ulcer healing
  - if given before endoscopy, decreases need for endoscopic therapeutic intervention
- for variceal bleeds, octreotide 50 µg loading dose followed by constant infusion of 50 µg/h and ABx for those with cirrhosis (reduces risk of infections)
- consider IV erythromycin (or metoclopramide) to accelerate gastric emptying prior to gastroscopy to remove clots from stomach
- H2-antagonists should not be used since they have minimal impact on rebleeding rates and need for surgery
- endoscopy (EGD): establish bleeding site + treat lesion
  - if bleeding peptic ulcer: most commonly used method of controlling bleeding is injection of epinephrine around bleeding point + thermal hemostasis (bipolar electrocoagulation or heater probe); less often thermal hemostasis may be used alone, but injection alone not recommended
  - endoclips
  - Hemospray™
  - dual therapy (more than one therapeutic intervention method) is standard of care and has greater efficacy than single therapy

Forrest Prognostic Classification of Bleeding Peptic Ulcers

Forrest Class	Type of Lesion	Risk of Rebleed (%)
I	Arterial bleeding (oozing/spurting)	55-100
IIa	Visible vessel	43
IIb	Sentinel clot	22
IIc	Hematin covered flat spot	10
III	No stigmata of hemorrhage	5

Lancet 1974;2:394-397

Prognosis
- 80% stop spontaneously
- peptic ulcer bleeding: low mortality (2%) unless rebleeding occurs (25% of patients, 10% mortality)
- endoscopic predictors of rebleeding (Forrest classification): spurt or ooze, visible vessel, fibrin clot
- can send home if clinically stable, bleed is minor, no comorbidities, endoscopy shows clean ulcer with no high-risk predictors of rebleeding
- esophageal varices have a high rebleeding rate (55%) and mortality (29%)



Overt GI bleeding (hematochezia, melena)
Yes
No
Upper and lower endoscopy
Source of bleeding found?
Yes: treat
No: wireless endoscopy capsule/ double balloon endoscopy*
Rule out non-GI sources of bleeding (e.g. menorrhagia, hemolysis)
Has the anemia resolved?
Yes: follow
No: proceed as if overt GI bleeding present

* Wireless endoscopy capsule results help double balloon endoscopy localize source of bleeding
- Angiography if overt bleeding hemodynamically significant, estimated >0.5 cc/min
- CT enterography if wireless endoscopy capsule/double balloon endoscopy not available

Figure 9. Approach to iron deficiency anemia

Management of Nonvariceal Upper Gastrointestinal Bleeding: Guideline Recommendations from the International Consensus Group
Ann Intern Med 2019;171:805-822

Pre-Endoscopic Management: In patients without cardiovascular disease, the suggested Hb threshold for blood transfusion is <80 g/L. The threshold is higher for patients with cardiovascular disease.

Endoscopic Management: Patients with acute UGIB should undergo endoscopy within 24 h of presentation. In patients with high-risk stigmata, thermocoagulation and sclerosant injection are recommended. TC-325, a hemostatic powder, can be used as a temporizing agent for actively bleeding ulcers.

Pharmacologic Management: High-dose PPI should be given for 3 d to patients with bleeding ulcers with high-risk stigmata who have undergone successful endoscopic therapy. Continued oral PPI therapy is recommended twice daily for 14 d, then once daily for a duration that depends on the nature of the bleeding lesion.

Esophageal Varices

Definition
- dilated esophageal veins connecting portal and systemic circulation

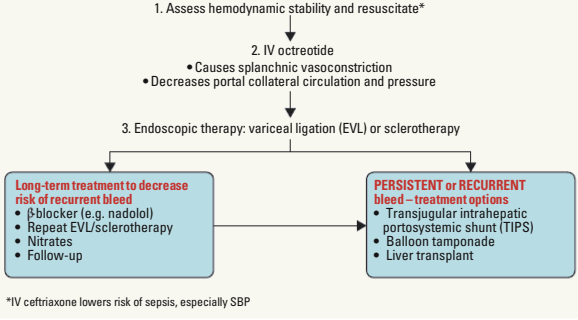
Etiology
- almost always due to portal hypertension

Clinical Features
- characteristically massive upper GI bleeding

Prognosis
- risk of bleeding: 30% in 1st yr
- risk of rebleeding: 50-70% (20% mortality at 6 wk)

Investigations
- endoscopy

Management
- empirical treatment with broad-spectrum antibiotics (such as ceftriaxone) reduces mortality in variceal bleeding and should be initiated as soon as variceal bleeding is suspected, as early administration is associated with a lower rebleeding rate and lower mortality



1. Assess hemodynamic stability and resuscitate*
2. IV octreotide
• Causes splanchnic vasoconstriction
• Decreases portal collateral circulation and pressure
3. Endoscopic therapy: variceal ligation (EVL) or sclerotherapy
Long-term treatment to decrease risk of recurrent bleed
• β-blocker (e.g. nadolol)
• Repeat EVL/sclerotherapy
• Nitrates
• Follow-up
PERSISTENT or RECURRENT bleed – treatment options
• Transjugular intrahepatic portosystemic shunt (TIPS)
• Balloon tamponade
• Liver transplant
*IV ceftriaxone lowers risk of sepsis, especially SBP

If varices isolated to stomach, think of splenic vein thrombosis

Gastric varices best treated by endoscopic injection of cyanoacetate ("crazy glue")

Figure 10. Management of bleeding esophageal varices

Mallory-Weiss Tear

Definition
- longitudinal laceration in gastric mucosa on lesser curvature near GE junction (20% straddle junction, 5% in distal esophagus)

Etiology
- due to rapid increases in gastric pressure from retching/vomiting against a closed glottis
- hiatus hernia often present

Clinical Features
- hematemesis ± melena, classically following an episode of retching without blood
- can lead to fatal hematemesis

Management
- 90% stop spontaneously
- if persistent: endoscopy with epinephrine injection ± clips or surgical repair

Lower Gastrointestinal Bleeding

Definition
- bleeding distal to ligament of Treitz

Etiology
- **anatomic**
  - diverticular
- **vascular**
  - angiodysplasia (small vascular malformations of the gut)
  - anorectal (hemorrhoids, fissures)
- **inflammatory**
  - infection
  - inflammatory bowel disease
  - colitis (ulcerative, infectious, radiation, ischemic) (see *Ulcerative Colitis, G25*)
- **neoplasm**
- polyp(s)
- post-polypectomy
- cancer

Lower GI Bleed

CHAND
Colitis (radiation, infectious, ischemic, IBD (UC > CD))
Hemorrhoids/fissure
Angiodysplasia
Neoplasm
Diverticular disease

Clinical Features
- hematochezia
- anemia
- occult blood in stool (no visible blood, detected via FIT)
- occasionally melena due to slow small bowel or right-colonic course

Treatment
- if blood per rectum with hemodynamic instability, stabilize patient (1-2 large bore IVs, IV fluids, monitor) and rule out upper GI source with endoscopy (EGD)
- send blood for CBC, cross and type, INR/PTT, electrolytes, BUN, Cr, LFTs
- initial examination of choice is colonoscopy to determine source of the bleeding

- if bleeding is severe or ongoing, consider radionuclide imaging or angiography (see Medical Imaging, MI16)
- treat underlying cause
  - majority of cases will stop bleeding spontaneously

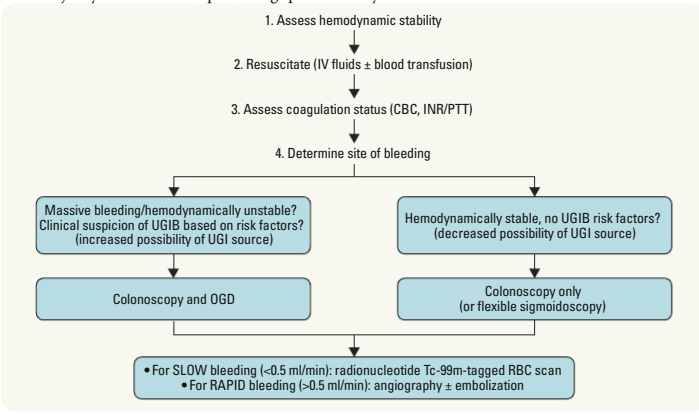


Figure 11. Approach to hematochezia

Always exclude upper GI lesion before localizing the site of the bleeding to the lower GI tract

Diverticular Bleeding

Etiology
- herniation of diverticula exposes vasa recta, increasing susceptibility to disruption
- bleeding most common from the right colon (thinner walled), although diverticula often develop throughout colon

Clinical Features
- painless hematochezia, acute onset
- stool can range from bright red to dark maroon; gelatinous clots often mixed in
- 80% of diverticular bleeding resolves spontaneously without intervention

Management
- if colonoscopy identifies source (rare), hemostatic therapy can be applied
- if ongoing, can consider embolization or surgery

Infectious Colitis

Etiology
- variety of pathogens; often due to *Campylobacter, Entamoeba histolytica, Salmonella, E. coli, Shigella*
- consider travel history, food exposures

Clinical Features
- bloody diarrhea, fever, abdominal pain

Management
- stool cultures to determine pathogen and guide management
- see *Acute Diarrhea, G15*

Colorectal Carcinoma

- see General Surgery and Thoracic Surgery, GS43

Colorectal Polyps

- see General Surgery and Thoracic Surgery, GS41

Familial Colon Cancer Syndromes

- see General Surgery and Thoracic Surgery, GS42

Benign Anorectal Disease

- see General Surgery and Thoracic Surgery, GS47

Liver

Investigations of Hepatobiliary Disease

A. Tests of Liver Function

Table 17. Liver Function Tests

Test	What Do Levels Correlate With?	Increased by	How to Interpret
Prothrombin Time (PT or INR)	Hepatic protein synthesis All coagulation factors except VIII	Increased by: Hepatocellular dysfunction Vitamin K deficiency (due to malnutrition, malabsorption, etc.)	PT/INR will promptly correct if vitamin K is administered, so increased PT/INR in absence of vitamin K deficiency is a reliable marker of hepatocellular dysfunction
Serum Albumin	Hepatic protein synthesis (and other causes listed in next column)	Decreased by: Hepatocellular dysfunction Malnutrition Renal or GI losses Significant inflammation Malignancy	Rule out potential causes other than hepatocellular dysfunction
Serum Direct Bilirubin*	Hepatic excretion from hepatocyte to biliary system	Increased by: Liver dysfunction	Conjugation is preserved even in end stage liver failure, thus increased direct bilirubin indicates liver dysfunction

*Serum Bilirubin
• canaliculus breakdown product of hemoglobin; metabolized in the reticuloendothelial system of liver, transported through biliary system, excreted via gut
• direct bilirubin = conjugated; indirect bilirubin = unconjugated

B. Tests of Liver Injury

Table 18. Liver Enzyme Profile

Profile	Liver Enzyme Change	Notes
Hepatocellular	↑ AST ↑ ALT	AST from multiple sources (especially muscle) ALT more specific to liver Elevation of both highly suggestive of liver injury
Cholestatic	↑ ALP ↑ GGT	Cholestasis = stasis of bile flow If ALP is elevated alone, rule out bone disease by fractionating ALP and/or checking GGT If ALP elevation out of proportion to ALT/AST elevation, consider: • Obstruction of common bile duct (e.g. extraluminal = pancreatic cancer, lymphoma; intraluminal = stones, cholangiocarcinoma, sclerosing cholangitis, helminths) • Predominant rise in hepatocellular enzyme possible in acute biliary obstruction secondary to a stone due to the sudden impairment in bile flow and because ALP is an inducible enzyme which takes time to rise • Destruction of microscopic ducts (e.g. PBC) • Bile acid transporter defects (e.g. drugs, intrahepatic cholestasis of pregnancy) • Infiltration of the liver (e.g. liver metastases, lymphoma, granulomas, amyloid)

Acute Viral Hepatitis (General)

Definition
- viral hepatitis lasting <6 mo

Clinical Features
- most are subclinical
- flu-like prodrome may precede jaundice by 1-2 wk
  - N/V, anorexia, headaches, fatigue, myalgia, low-grade fever, arthralgia, and urticaria (especially HBV)
- only some progress to icteric (clinical jaundice) phase, lasting days to weeks
  - pale stools and dark urine 1-5 d prior to icteric phase
  - hepatomegaly and RUQ pain
  - splenomegaly and cervical lymphadenopathy (10-20% of cases)

Quick Reference Diagnostic Tests for Common Liver Conditions

Disease	Diagnostic Tests
Viral Hepatitis	Anti-HAV IgM, HBsAg, anti-HCV
Autoimmune Hepatitis	ANA, SMA, LKM, IgG levels
Wilson's Disease	Ceruloplasmin, liver biopsy
Hereditary Hemochromatosis	Iron saturation, ferritin, HFE genetic testing
α1-Antitrypsin Deficiency	α1-antitrypsin levels/ genotyping, liver biopsy
Drug-induced Liver Injury	Careful medication history, liver biopsy
NAFLD/Nonalcoholic Steatohepatitis (NASH)	U/S, metabolic testing, liver biopsy

ANA = anti-nuclear antibody; SMA = smooth muscle antibody; LKM = liver-kidney microsomal-1 antibody; HFE = hemochromatosis gene

DDx for Hepatomegaly
- Congestive (right heart failure, Budd-Chiari syndrome)
- Infiltrative
- Malignant (primary, secondary, lymphoproliferative, leukemia)
- Benign (fatty liver, cysts, hemochromatosis, extramedullary hematopoiesis, amyloid)
- Proliferative
- Infectious (viral, tuberculosis, abscess, echinococcus)
- Inflammatory (granulomas (sarcoid), histiocytosis X)

All clotting factors except factor VIII and von Willebrand factor are exclusively synthesized in the liver. Factor VIII is also produced in the endothelium. In cirrhosis, risk of bleeding does not correlate closely with elevations in INR/ PTT since so many of the proteins in the coagulation cascade are affected

ALT > AST = most causes of hepatitis
AST > ALT = alcoholic liver disease or other causes of hepatitis (i.e. non-alcoholic liver disease) that have progressed to advanced cirrhosis

Serum Transaminases >1000 due to
- Viral hepatitis
- Drugs/toxins
- Autoimmune hepatitis
- Hepatic ischemia
- Less often, common bile duct stone

Investigations
- AST and ALT (>10-20x normal in hepatocellular necrosis)
- ALP minimally elevated
- viral serology, particularly IgM antibody directed to the virus

Treatment
- supportive (hydration, diet)
- usually resolves spontaneously, but if severe HBV infection, treatment with antiviral agent such as tenofovir or entecavir can be considered; in acute hepatitis C, antiviral treatment should be considered (see *Hepatitis C Virus, G34*)
- indications for hospitalization: encephalopathy, coagulopathy, severe vomiting, hypoglycemia

Prognosis
- poor prognostic indicators: comorbidities, persistently high bilirubin (>340 mmol; 20 mg/dL), increased INR, decreased albumin, hypoglycemia

Complications
- cholestasis (most commonly associated with HAV infection)
- hepatocellular necrosis: AST, ALT >10-20x normal, ALP and bilirubin minimally increased, increased cholestasis

Hepatitis A Virus

- RNA virus
- fecal-oral transmission; incubation period 4-6 wk
- diagnosed by elevated transaminases, positive anti-HAV IgM
- in children: characteristically asymptomatic
- in adults: fatigue, nausea, arthralgia, fever, jaundice, hepatomegaly
- can cause ALF and subsequent death (<1-5%)
- can relapse (rarely), but never becomes chronic
- treatment is supportive (no specific treatments available, disease is often self-limiting)
- preventable by vaccination

Hepatitis B Virus

Table 19. Hepatitis B Serology

	HBsAg	Anti-HBs	HBeAg	Anti-HBe	Anti-HBc	Liver Enzymes
Acute HBV	+	–	+	–	IgM	
Chronic (HBe-Ag positive) HBV (generally high HBV- DNA)	+	–	+	–	IgG	ALT, AST may or may not be elevated
Chronic (HBe-Ag negative) HBV (generally low HBV- DNA)	+	–	–	+	IgG	ALT, AST may or may not be elevated
Resolved Infection	–	±	–	±	IgG	
Immunization	–	+	–	–	–	

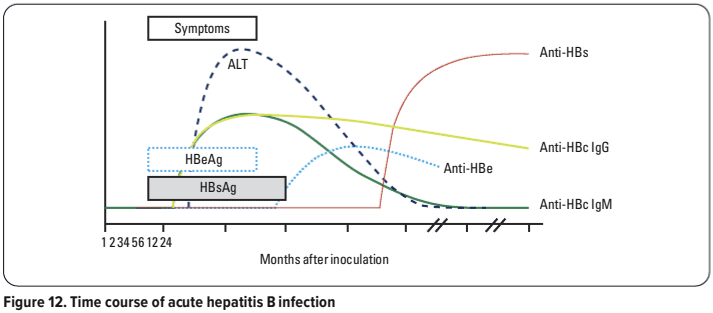

Figure 12. Time course of acute hepatitis B infection

Alcoholic Hepatitis: history of chronic EtOH use (possibly with recent increased consumption, although often patient may have stopped drinking in the days-weeks prior to presentation due to symptoms), RUQ abdominal pain, AST/ALT >2, AST usually <300, low grade fever, mildly elevated WBC

Major Sources of ALP
Hepatobiliary tree
Bone
Placenta
Intestine

DDx for Hepatitis
Viral infection
Alcohol
Drugs
Immune-mediated
Toxins

Without treatment, 8-20% of those with ongoing immunoactive chronic hepatitis can develop cirrhosis within 5 yr. In contrast, those in the immune tolerant phase (with extremely high HBV-DNA levels) are at minimal risk for liver fibrosis as they do not have immune-mediated liver injury

Risk of HCC in HBV increases with increasing age, which is likely a surrogate for increasing liver fibrosis/cirrhosis, and serum HBV-DNA
Risk of HCC in HCV increases only after cirrhosis develops

HCV (and HBV) treatment lowers the risk of HCC

Risk Factors for Progression
EtOH
HIV coinfection
Old age at diagnosis

Epidemiology

- 4 phases of chronic hepatitis B: not all carriers will go through all 4 phases, but all carriers will have positive HBsAg
    1. **immune tolerance**: extremely high HBV-DNA (>20000 IU/mL), HBeAg positive, but normal ALT/AST; due to little immune control and minimal immune-mediated liver damage; characteristic of perinatal infection (or 'incubation period' in adult with newly-acquired HBV)
    2. **immune clearance (or immunoactive):** HBV-DNA levels (>20000 IU/mL), HBeAg positive; due to immune attack on the virus and immune-mediated liver damage; characterized by progressive disease without treatment and increasing liver fibrosis (sometimes progressing to cirrhosis and/or HCC); likely to benefit from treatment
    3. **inactive carrier (immune control):** lower HBV-DNA (<2000 IU/mL), HBeAg negative, anti-HBe positive, ALT/AST normal; due to immune control without immune-mediated liver damage; risk of reactivation to phase 2 (clinically resembles acute hepatitis B), especially with immunosuppression e.g. corticosteroids or chemotherapy
    4. **HBeAg-negative chronic hepatitis (immune escape) ("core or precore mutant"):** elevated HBV-DNA (>2000 IU/mL), HBeAg negative because of pre-core or core promoter gene mutation, anti-HBe positive, ALT/AST high; characterized by progressive disease without treatment and increasing liver fibrosis (sometimes progressing to cirrhosis and/or HCC); likely to benefit from treatment

Treatment

- counselling: 40% of men and 10% of women with perinatal infection without treatment will die from HBV-related complications
- HCC screening with U/S q6 mo, especially if high serum HBV-DNA levels, cirrhosis, men, (ages >40 in Asian men, >50 in Asian women, and >20 in African descent)
- contexts to consider pharmacological therapy:
    1. HBeAg positive and HBV-DNA >20000 IU/mL and elevated ALT
    2. HBeAg negative and HBV-DNA >2000 IU/mL and elevated ALT with or without stage ≥2 fibrosis on liver biopsy
    3. to prevent flare when placed on immunosuppressive therapy such as prednisone, chemotherapy, biologics, etc.
- treatment goal: reduce serum HBV-DNA to undetectable level
    - prolonged immune-mediated damage leads to higher risk of liver fibrosis
- treatment options: tenofovir, entecavir, lamivudine (not preferred due to high rate of developing resistance)
- vaccinate against HAV if serology negative (to prevent further liver damage)
- follow blood and sexual precautions
- vaccinate household contacts

Hepatitis D Virus

- defective RNA virus requiring HBsAg for entry into hepatocyte, therefore infects only patients with HBV; causes more aggressive disease than HBV alone
- coinfection: acquire HDV and HBV at the same time
- superinfection: new acquisition of HDV on a background of chronic HBV infection (e.g. injection drug users)
- HDV can present as ALF and/or accelerate progression to cirrhosis
- treatment: low-dose interferon (20% response) and liver transplant for end-stage disease

Hepatitis C Virus

- RNA virus (7 genotypes; genotype 1 is most common in North America)
- blood-borne transmission; sexual transmission is "inefficient"
- major risk factor: injection drug use
- other risk factors: blood transfusion received before 1992 (or received in developing world), tattoos, intranasal cocaine use
- acute hepatitis C occurs 2-6 mo after transmission
    - symptoms mild and vague (fatigue, malaise, nausea) therefore not commonly diagnosed in acute stage
    - almost 30% of cases of acute hepatitis C are cleared spontaneously without therapy

Diagnosis

- suspected on basis of elevated ALT/AST and positive serum anti-HCV
- diagnosis established by detectable HCV-RNA in serum
- normal hepatocellular enzymes does not rule out active disease or presence of advanced fibrosis
- abdominal U/S and transient elastography (FibroScan®) to assess the staging of the disease and the degree of fibrosis

In acute hepatitis B, HDV coinfection increases severity of hepatitis but does not increase risk of progression to chronic hepatitis. However in the context of chronic hepatitis B, superinfection with HDV increases progression to cirrhosis

Causes of Elevated Serum Transaminases in Chronic Hepatitis B
Active hepatitis (either immune clearance phase in HBeAg-positive individuals or HBeAg-negative active hepatitis)
Reactivation (e.g. due to immunosuppression)
Hepatitis D
Other liver insult (fatty liver, EtOH, drugs, hepatitis A)

Risk Factors for Contracting Hepatitis B
Infants born to a hepatitis B-infected parent (maternal or paternal)
Unprotected sexual intercourse (especially if multiple partners)
Needle sharing (e.g. injection drug users)
Travel to endemic regions
Exposure to human blood, semen, and other bodily fluids

Clinical Features of Hepatitis B
Many patients are asymptomatic, both in the acute and chronic phases
Acute hepatitis can manifest as jaundice, nausea, arthritis, or constitutional symptoms
Patients with chronic hepatitis can be asymptomatic, experience exacerbations, develop extrahepatic complications (e.g. glomerular disease), or develop cirrhosis

Treatment

- blood-borne precautions; vaccinate for hepatitis A and B if serology negative; avoid EtOH
- clearest indication for treatment is in subgroups likely to develop clinically significant liver disease, i.e. persistently elevated transaminases, liver biopsy showing moderate-advanced fibrosis/cirrhosis, and at least moderately severe necrosis/inflammation
  - now that a safe, effective cure is available, the risk/benefit ratio favours treating everyone with chronic hepatitis C
- choice and duration of treatment depends mostly on whether patient is cirrhotic (and if so, whether decompensated or not), prior treatment history, and possibly genotype (but less so with availability of pan-genotypic therapies)
- direct acting antiviral (DAA) tablets (Maviret®, a combination of glecaprevir and pibrentasvir, and Epclusa®, a combination of velpatasvir and sofosbuvir) are the most commonly used
- other oral interferon-free regimens (for all genotypes) (e.g. sofosbuvir/ledipasvir, ombitasvir/paritaprevir/ritonavir+dasabuvir, or elbasvir/grazoprevir, and sofosbuvir/velpatasvir) are also available but used less frequently
- it is important to check for hepatitis B prior to therapy as direct acting antivirals may lead to reactivation of hepatitis

Prognosis

- 80% of acute hepatitis C cases become chronic (of these, 20% evolve to cirrhosis within 20 years of exposure)
- risk of HCC increases if cirrhotic
- can cause cryoglobulinemia; associated with membranoproliferative glomerulonephritis, lymphoma

Table 20. Characteristics of the Viral Hepatitides

	HAV	HBV	HCV	HDV	HEV	CMV	EBV	Yellow Fever
Virus Family	*Picomaviridae*	*Hepadnaviridae*	*Flaviviridae*	*Deltaviridae*	*Caliciviridae*	*Herpesviridae*	*Herpesviridae*	*Flavivirus*
Genome	RNA	DNA	RNA	RNA	RNA	DNA	RNA	RNA
Envelope	No	Yes	Yes	Yes	No	Yes	Yes	Yes
Transmission	Fecal-oral	Parenteral/sexual or equivalent Vertical	Parenteral/sexual (transfusion, IV drug user, sexual (<HBV)) 40% have no known risk factors	Non-parenteral (close contact in endemic areas) Parenteral (blood products, IV drug user) —sexual transmission is inefficient	Fecal-oral (endemic: Africa, Asia, central America, India, Pakistan)	Close contacts, most body fluids	Saliva-oral	Vector (mosquito)
Incubation	4-6 wk	6 wk-6 mo	2-26 wk	3-13 wk	2-8 wk	20-60 d	30-50 d	3-6 d
Onset	Usually abrupt	Usually insidious	Insidious	Usually abrupt	Usually abrupt	Variable	Variable	Usually abrupt
Communicability	2-3 wk in late incubation to early clinical phase Acute hepatitis in most adults, 10% of children	HBsAg+ state highly communicable Increased during third trimester or early post-partum	Communicable prior to overt symptoms and throughout chronic illness	Infectious only in presence of HBV (HBsAg required for replication)	Unknown	Variable – dormant or persistent	Highly communicable during year after primary infection but never zero	Variable, vector-dependent
Chronicity	None, although can relapse	5% adults, 90% infants	80%, 20% of which develop cirrhosis	5%	None	Common; latent	Common; latent	Infection confers lifelong immunity
Serology	Anti-HAV (IgM)	**See** *Table 19, G33*	HCV-RNA Anti-HCV (IgG/IgM)	HBsAg Anti-HDV (IgG/IgM)	Anti-HEV (IgG/IgM)	Anti- CMV (IgM/IgG)	Monospot; anti-EBV IgM/IgG, EBV-DNA quantitation	Anti-YF (IgM/IgG)
Vaccine	Havrix®, 2 doses q6 mo, combined with Twinrix® at 0, 7, and 21 d	Recombivax® HBTM, ages 11-15, 2 doses q6 mo	No	No	No	No	No	YF-VAX®, 1 dose booster q10 yr
Management	General hygiene Treat close contacts (anti-HAV Ig) Prophylaxis for high-risk groups (HAV vaccine ± HAV Ig) unless immune	Prevention: HBV vaccine and/or hepatitis B Ig (HBIg) for needlestick, sexual contact, infants of infected mothers (unless already immune) Rx: oral antivirals vs. interferon if indications met	Prevention: no vaccine Rx: interferon + ribavirin ± protease inhibitor; although all oral antiviral (IFN-free) therapies now available are highly efficacious	Prevention: HBV vaccine	Prevention: general hygiene, no vaccine	In high-risk transplant patients: CMV Ig and antivirals (ganciclovir, valganciclovir)	Supportive treatment post-infection	Prevention: vaccine Supportive treatment post infection
Acute Mortality	0.1-0.3%	0.5-2%	1%	2-20% coinfection with HBV, 30% superinfection Predisposes HBV carriers to more severe hepatitis and faster progression to cirrhosis	1-2% overall, 10-20% in pregnancy	Rare in immunocompetent adults	Rare	20-60% in developing countries
Oncogenicity	No	Yes	Yes	Yes	No	No	Yes	No
Complications	Can cause ALF and subsequent death (<1-5%)	HCC secondary to cirrhosis, serum sickness-like syndrome, glomerulonephritis, cryoglobulinemia, polyarteritis nodosa, porphyria cutanea tarda	HCC in 2-5% of cirrhosis per yr, cryoglobulinemia, B-cell non-Hodgkin lymphoma	Leukocytoclastic vasculitis, membranous glomerulonephropathy	Mild, except in third trimester (10-20% ALF)	5% of newborns with multiple handicaps Immunocompromised patients at risk of CMV-induced hepatitis, retinitis, colitis, esophagitis, pneumonitis	Associated with Burkitt's lymphoma and nasopharyngeal carcinoma (rare in Western world)	Can cause a recurrent toxic phase with liver damage, GI bleeding, and high mortality rates

Autoimmune Liver Disease

- diagnosis of exclusion: rule out viruses, drugs/EtOH, metabolic, or genetic causes
- can be severe: 40% mortality at 6 mo without treatment
- extrahepatic manifestations
  - sicca, Raynaud's, thyroiditis, Sjögren's, arthralgias
  - hypergammaglobulinemia (particularly elevated IgG)
  - typical auto-antibodies: ANA and/or anti-smooth muscle antibody
  - infrequently may see anti-LKM elevation (liver kidney microsome), especially in children
  - can have false positive viral serology (especially anti-HCV)
  - biopsy – periportal (zone 1) and interface inflammation and necrosis
- treatment: corticosteroids (80% respond) ± azathioprine (without this, most will relapse as corticosteroids are withdrawn)

Drug-Induced Liver Disease

Table 21. Classification of Hepatotoxins

	Predictable	Idiosyncratic
Example	Acetaminophen, CCl4	Phenytoin, INH
Dose-Dependence	Usual	Unusual
Latent Period	Hours-days	Weeks-months
Host Factors	Not important	Very important

Hy's Law: drug-induced hepatocellular jaundice indicates a mortality of at least 10%

- many different patterns of liver injury (i.e. hepatocellular, cholestatic, mixed, granulomatous, ALF) can be seen in drug-induced liver injury and thus this requires a high index of suspicion
- see: LiverTox for Information regarding drug-specific risks and patterns of hepatotoxicity (http://livertox.nih.gov)

Specific Drugs

- acetaminophen
  - metabolized by hepatic cytochrome P450 system
  - can cause ALF (transaminases >1000 U/L followed by jaundice and encephalopathy)
  - requires 10-15 g in healthy individuals, 4-6 g in alcoholics/anticonvulsant users
  - mechanism: high acetaminophen dose saturates glucuronidation and sulfation elimination pathways → reactive metabolite (NAPQI (n-acetyl-p-benzoquinone imine)) is formed → covalently binds to hepatocyte membrane
  - presentation
    - first 24 h: nausea and vomiting (usually within 4-12 h of overdose)
    - 24-48 h: asymptomatic, but ongoing hepatic necrosis resulting in increased transaminases
    - >48 h: continued hepatic necrosis possibly complicated with ALF or resolution
    - note: potential delay in presentation in sustained-release products
  - blood levels of acetaminophen correlate with the severity of hepatic injury, particularly if time of ingestion known
  - therapy
    - gastric lavage/emesis (if <2 h after ingestion)
    - oral activated charcoal
    - N-acetylcysteine (NAC – Mucomyst®) can be given PO or IV (most effective within 8-10 h of ingestion, but should be given regardless of time of ingestion)
      - promotes hepatic glutathione regeneration
    - no recorded fatal outcomes if NAC given before increase in transaminases
    - NAC use should be determined by the Rumack-Matthew nomogram or if unclear, time of ingestion
- antimicrobials are the most common class of causative agent (e.g. amoxicillin-clavulanate, isoniazid, nitrofurantoin, sulfamethoxazole-trimethoprim)
- chlorpromazine: cholestasis in 1% after 4 wk; often with fever, rash, jaundice, pruritus, and eosinophilia
- Isoniazid (INH)
  - 20% develop elevated transaminases but <1% develop clinically significant disease
  - susceptibility to injury increases with age
- Methotrexate (MTX)
  - causes fibrosis/cirrhosis; increased risk in the presence of obesity, DM, alcoholism (i.e. with underlying risk for pre-existing fatty liver)
  - scarring develops without symptoms or changes in liver enzymes, therefore biopsy may be needed in long-term treatment
- amiodarone: can cause same histology and clinical outcome as alcoholic hepatitis
- others: azoles, statins, methyldopa, phenytoin, propylthiouracil (PTU), rifampin, sulfonamides, tetracyclines
- herbs: khat, chaparral, Chinese herbs (e.g. germander, comfrey, bush tea). Weight loss supplements (containing green tea extract) have been associated with cases of acute liver failure. Body-building supplements have been associated with prolonged cholestatic jaundice)

Wilson's Disease

Definition
- autosomal recessive defect in copper elimination (gene *ATP7B*)

Etiology
- decreased biliary excretion of copper plus decreased incorporation of copper into ceruloplasmin
- worldwide incidence: 1 in 40000

Clinical Features
- liver: acute hepatitis, ALF, chronic active hepatitis, cirrhosis, low-risk of HCC
- eyes: Kayser-Fleischer rings (copper deposits in Descemet's membrane); more common in patients with CNS involvement, present in only 50% of isolated liver involvement
- CNS: basal ganglia (wing flapping tremor, Parkinsonism), cerebellum (dysarthria, dysphagia, incoordination, ataxia), cerebrum (psychosis, affective disorder)
- kidneys: Fanconi's syndrome (proximal tubule transport defects) and stones
- blood: intravascular hemolysis; may be initial presentation in fulminant hepatitis
- joints: arthritis, bone demineralization, calcifications

Clinical Manifestations of Wilson's Disease

ABCD
Asterixis
Basal ganglia degeneration: suspect if parkinsonian features in the young
Ceruloplasmin decreases
Cirrhosis
Corneal deposits (Kayser-Fleischer ring)
Copper
Dementia

Investigations
- suspect if increased liver enzymes with clinical manifestations at young age (<40); especially combination of liver disease with dystonia, psychiatric symptoms
- screening tests
  1. reduced serum ceruloplasmin (<50% of normal)
  2. Kayser-Fleischer rings (usually require slit-lamp examination)
  3. increased urinary copper excretion (measure 24-hour urine copper)
- gold standard
  1. increased copper on liver biopsy by quantitative assay
  2. genetic analysis imperfect as many mutations in ATP7B are possible
- first-degree relatives should also be considered for screening

Treatment
- 4 drugs available
  1. penicillamine: chelates copper, but poorly tolerated
  2. trientine: chelates copper
  3. zinc: impairs copper excretion in stool and decreases copper absorption from gut. Often used as maintenance therapy or in neurologic presentations
  4. tetrathiomolybdate: preferred if neurological involvement
- hepatic presentations are best treated with a trientine + zinc combination
- liver transplant in severe cases of liver failure

Hemochromatosis

Definition
- excessive iron storage causing multiorgan system dysfunction (liver, in particular) with total body iron stores increased to 20-40 g (normal 1 g)

Etiology
- primary (hereditary) hemochromatosis
  - usually related to HFE mutation (see Epidemiology below)
  - decreased hepcidin production results in increased GI absorption and tissue iron deposition despite adequate iron stores
- secondary hemochromatosis
  - parenteral iron overload (e.g. transfusions, hemodialysis, parenteral iron injections)
  - excessive oral iron intake (e.g. dietary iron overload)
  - other liver diseases (e.g. EtOH, NAFLD, viral hepatitis)
  - iron-loading anemias (hemolytic, sideroblastic, aplastic, thalassemia major)
  - ineffective erythropoiesis

Epidemiology
- classic hereditary hemochromatosis most common in Northern European descent
- mainly caused by mutations in the *HFE* gene (e.g. C282Y/C282Y, C282Y/H63D), which has a homozygous genetic prevalence of 1/400
  - C282Y/H63D only potentially causative as compound heterozygote
- very rare non-HFE mutations also exist (e.g. ferroportin, hemojuvelin, hepcidin, aceruloplasminemia)

Hemochromatosis Clinical Features

ABCDH
Arthralgia
Bronze skin
Cardiomyopathy, cirrhosis of liver
Diabetes (pancreatic damage)
Hypogonadism (anterior pituitary damage)

Clinical Features
- usually presents with trivial elevation in serum transaminases although often picked up incidentally when iron studies noted to be elevated
- liver: cirrhosis (less common nowadays due to earlier detection), HCC (200x increased risk)
- pancreas: DM, chronic pancreatitis
- skin: bronze or grey (due to melanin, not iron)
- heart: diastolic dysfunction and arrhythmias in early stages with dilated cardiomyopathy in later stages
- pituitary: hypogonadotropic hypogonadism (impotence, decreased libido, amenorrhea)
- joints: arthralgia (any joint, but especially metacarpophalangeal joints), chondrocalcinosis

Ferritin may never normalize if other causes of high ferritin present (e.g. fatty liver from metabolic syndrome or EtOH)

Investigations
- screening for individuals with clinical features and/or family history (25% chance of sibling having the disease)
  - transferrin saturation (free Fe^{2+}/total iron binding capacity (TIBC)) >45%
  - serum ferritin >400 ng/mL
  - *HFE* gene analysis: 90% of primary hemochromatosis involves C282Y allele, while H63D and S65C alleles also commonly involved and screened
- MRI (often used instead of a liver biopsy)
  - non-invasive approach to assess iron overload
  - most sensitive and specific modality in the diagnosis of hemochromatosis
  - serum ferritin >1000 ng/mL or symptoms of organ injury (e.g. elevated LFTs, symptoms of heart failure)
  - can be used to follow treatment by phlebotomies
- liver biopsy (generally used to detect cirrhosis or if potential for other causes of liver disease)
  - markers of advanced fibrosis: if any of the following are present at the time of diagnosis → ages >40, elevated liver enzymes, or ferritin >1000 ng/mL
  - considered if compound heterozygote and potential other cause of liver injury (e.g. NAFLD, excess EtOH, hepatitis)
  - if C282Y/C282Y and no markers of advanced fibrosis, then biopsy generally not needed
- HCC screening if cirrhosis

Treatment
- phlebotomy: weekly or q2 wk then lifelong maintenance phlebotomies q2-6 mo, generally aiming for ferritin of 50-100 ng/mL
- chelation therapy such as deferoxamine if phlebotomy contraindicated (e.g. cardiomyopathy, anemia)
- primary hemochromatosis responds well to phlebotomy
- secondary hemochromatosis usually requires chelation therapy (administration of agents that bind and sequester iron, and then excreted)

Prognosis
- normal life expectancy if treated before the development of cirrhosis or DM

Alcoholic Liver Disease

Definition
- spectrum of diseases, ranging from:
  - fatty liver (common amongst individuals with EtOH use disorder): reversible if EtOH stopped
  - alcoholic hepatitis (35% of individuals with EtOH use disorder): usually reversible if EtOH stopped
  - cirrhosis (10-15% of individuals with EtOH use disorder): irreversible

Standard Drink Equivalent
1 standard drink = 14 g EtOH
= 12 oz beer (5% alcohol)
= 5 oz wine (12-17%)
= 3 oz fortified wine (17-22%)
= 1.5 oz liquor (40%)
Tip: percentage EtOH multiplied by oz in 1 standard drink roughly equals 60

Pathophysiology
- several mechanisms, poorly understood
- ethanol oxidation to acetaldehyde
  - reduces NAD+ to NADH; increased NADH decreases ATP supply to liver, impairing lipolysis so fatty acids and triglycerides accumulate in liver
  - binds to hepatocytes evoking an immune reaction
- EtOH increases gut permeability leading to increased bacterial translocation
- EtOH metabolism causes:
  - relative hypoxia in liver zone III (near central veins; poorly oxygenated) > zone I (around portal tracts, where oxygenated blood enters)
  - necrosis and hepatic vein sclerosis
- histology of alcoholic hepatitis
  - ballooned (swollen) hepatocytes often containing Mallory bodies, characteristically surrounded by neutrophils
  - large fat globules
  - fibrosis: space of Disse and perivenular

Biopsy + Histology of Alcoholic Hepatitis (triad)

Hepatocyte necrosis with surrounding inflammation in zone III

Mallory bodies (intracellular eosinophilic aggregates of cytokeratins)

Chicken-wire fibrosis (network of intralobular connective tissue surrounding cells and venules)

Clinical Features
- >2-3 standard drinks/d in females and >3-6 standard drinks/d in men for >10 yr leads to cirrhosis, but only in about 10-20% of those who consume this amount daily on a continuous basis; cirrhosis risk increases with amount of EtOH consumed above threshold
- clinical findings do not accurately predict type of liver involvement
- fatty liver
  - mildly tender hepatomegaly; jaundice rare
  - mildly increased transaminases <5x normal
- alcoholic hepatitis
  - variable severity: mild to fatal liver failure
  - mild: stops drinking because feels unwell, resumes when feeling better (if assessed, findings of hepatitis, potentially mild jaundice, and mildly elevated INR)
  - severe: stops drinking but feels unwell, low grade fever, RUQ discomfort, increased WBC count – mimics right lower lobe pneumonia and cholecystitis

Investigations
- blood tests are non-specific, but in general
  - AST:ALT >2:1 (both usually <300)
  - CBC: increased mean corpuscular volume (MCV), increased WBC often seen with alcoholic hepatitis but not necessarily in other alcohol-related liver injury
  - increased GGT

Treatment
- alcohol cessation (see Psychiatry, PS28)
  - Alcoholics Anonymous (or similar programs), disulfiram, naltrexone, acamprosate
- multivitamin supplements (especially thiamine)
- caution with drugs metabolized by the liver
- prednisolone if severe alcoholic hepatitis based on Maddrey's discriminant function or Model for End-Stage Liver Disease (MELD) score as described in Prognosis
  - pentoxifylline less used since most definitive trial did not demonstrate efficacy

Prognosis
- Maddrey's discriminant function (based on PT and bilirubin) and MELD predict mortality and guide treatment (consideration of corticosteroids for severe disease based on Maddrey ≥32 or MELD ≥21)
- bilirubin response at day 7 of corticosteroids (Lille model) also factors into prognosis and decision on whether to continue full course of corticosteroids if started
- fatty liver: complete resolution with cessation of EtOH intake
- alcoholic hepatitis mortality
  - immediate: 30%-60% in the first 6 mo if severe
  - with continued EtOH: 70% in 5 yr
  - with cessation: 30% in 5 yr

GI Complications of Alcohol Use

Esophagus
Mallory-Weiss tear
Esophageal varices (secondary to portal hypertension)

Stomach
Alcoholic gastritis

Pancreas
Acute pancreatitis
Chronic pancreatitis

Liver
Alcoholic hepatitis
Fatty liver
Cirrhosis
Hepatic encephalopathy
Portal hypertension
Ascites
HCC

Non-Alcoholic Fatty Liver Disease

Definition
- spectrum of disorders characterized by macrovesicular hepatic steatosis, sometimes with inflammation and/or fibrosis
- most common cause of liver disease in North America

Etiology
- pathogenesis not well elucidated; insulin resistance implicated as key mechanism, leading to hepatic steatosis
- histological changes indistinguishable from those of alcoholic hepatitis despite negligible history of EtOH consumption

Risk Factors
- component of the metabolic syndrome along with obesity, T2DM, HTN, hypertriglyceridemia
- other less common causes such as medications (e.g. tamoxifen, corticosteroids, MTX), Wilson's, TPN, rapid weight loss, and others

Clinical Features
- often asymptomatic
- may present with fatigue, malaise, and vague RUQ discomfort

Investigations
- elevated serum AST, ALT ± ALP; AST/ALT <1
- presents as echogenic liver texture on U/S
- non-invasive testing of fibrosis: FIB4, NAFLD fibrosis score, FibroTest™, FibroScan®
- liver biopsy cannot distinguish fatty liver from alcoholic vs. non-alcoholic, but considered when investigating alternative etiologies or assessing for level of fibrosis

Treatment
- mainstay is gradual weight loss (0.5-1 kg/wk) as rapid weight loss can worsen liver disease
  - ideally, aim to lose at least 7-10% of body weight
- evidence for the use of pharmacologic agents such as pioglitazone and liraglutide, but potential benefits must be balanced with associated adverse effects (e.g. weight gain and CHF with pioglitazone)
- some evidence for vitamin E (800 IU daily) if there is hepatic inflammation in non-diabetic, non-cirrhotic patients
- some evidence for benefits of coffee drinking (3 cups/d) and vitamin D
- consideration for bariatric surgery
- GLP-1 analogues (e.g. semaglutide) do not appear to directly improve liver inflammation in NAFLD, but may indirectly help through promotion of weight loss

Prognosis
- main causes of death, particularly in non-cirrhotic group, are cardiovascular disease and malignancy
- better prognosis than alcoholic hepatitis
  - <25% progress to cirrhosis over a 7-10 yr period
- risk of progression increases if inflammation or scarring occurs alongside fat infiltration (non-alcoholic steatohepatitis)
- other clinical indicators of unfavourable prognosis: obesity, T2DM, age, metabolic syndrome, higher levels of fibrosis

Acute Liver Failure (formerly Fulminant Hepatic Failure)

Definition
- severe decline in liver function characterized by coagulation abnormality (INR >1.5) and encephalopathy
- in setting of previously normal liver
- rapid (<26 wk duration)

Figure 13. Progression of liver dysfunction based on liver function tests – the "W"

Etiology
- drugs (especially acetaminophen), hepatitis B (measure anti-HBc, IgM fraction because sometimes HBV-DNA and even HBsAg rapidly become negative), hepatitis A, hepatitis C (rare), ischemic, autoimmune hepatitis, Wilson disease, idiopathic

Treatment
- correct hypoglycemia, monitor level of consciousness, prevent GI bleed with PPI, monitor for infection and multiorgan failure (usually requires ICU)
- consider liver biopsy before INR becomes too high
- chief value of biopsy is to exclude chronic disease, less helpful for prognosis
- liver transplant (King's College criteria can be used as prognostic indicator): consider early, especially if time from jaundice to encephalopathy >7 d (e.g. not extremely rapid), ages <10 or >40, cause is drug or unknown, bilirubin >300 µmol/L, INR >3.5, creatinine >200 µmol/L

Cirrhosis

Definition
- liver damage characterized by diffuse distortion of the basic architecture with fibrosis and formation of regenerative nodules
- biopsy gold standard for diagnosis
- compensated cirrhosis = absence of complications, can last for 10-20 yr with almost normal life expectancy
- decompensated cirrhosis = development of complications such as ascites (most common), variceal bleeding, encephalopathy

Etiology
- fatty liver (alcoholic or NAFLD)
- chronic viral hepatitis (B, B+D, C; not A or E)
- autoimmune hepatitis
- drugs (e.g. chronic MTX or amiodarone use)
- hereditary hemochromatosis
- PBC
- chronic hepatic congestion
  - cardiac cirrhosis (chronic right heart failure, constrictive pericarditis)
  - hepatic vein thrombosis (Budd-Chiari)
- cryptogenic (i.e. no identifiable cause, although many of these patients may represent "burnt-out non-alcoholic steatohepatitis (NASH)")
- rare: Wilson's disease, Gaucher's disease, α1-antitrypsin deficiency

MELD-Na (Model for End-Stage Liver Disease)
Predicts 3 mo survival and used to stratify patients on transplant list
Based on creatinine, INR, total bilirubin, and serum sodium concentration

MELD 3.0
Updated score that includes new variables such as female sex and serum albumin

Investigations

- definitive diagnosis is histologic (liver biopsy)
- other tests may be suggestive
- blood work
  - fall in platelet count <150 is the earliest finding
  - in late stages of cirrhosis, rise in INR, fall in albumin, rise in bilirubin
  - elevated bilirubin is usually seen in more advanced disease or in the setting of a concurrent insult
  - in very advanced cirrhosis (pre-terminal event), may also see hypoglycemia but this is more often a feature seen in severe ALF
- FibroTest™: combination of various clinical and biochemical markers that can predict degree of fibrosis
- imaging
  - U/S is the primary imaging modality but only finds advanced cirrhosis
  - CT to look for varices, nodular liver texture, splenomegaly, ascites
  - transient elastography (FibroScan®): non-invasive tool using elastography for measuring liver compliance (variable availability)
    - rapidly replacing liver biopsy to determine extent of liver fibrosis and make the diagnosis of cirrhosis
- gastroscopy: varices or portal hypertensive gastropathy

Treatment

- treat underlying disorder
- decrease insults (e.g. EtOH cessation, hepatotoxic drugs, immunize for hepatitis A and B if non-immune)
- follow patient for complications (esophageal varices, ascites, HCC)
- prognosis: Child-Pugh Score and MELD score
- liver transplantation for end-stage disease; use MELD score (e.g. MELD ≥15)

Table 22. Child-Pugh Score and Interpretation

Classification	1	2	3
Serum bilirubin (μmol/L)	<34	34-51	>51
Serum albumin (g/L)	>35	28-35	<28
INR	<1.7	1.7-2.3	>2.3
Presence of ascites	Absent	Controllable	Refractory
Encephalopathy	Absent	Minimal	Severe
Interpretation			
Points	Class	Life Expectancy	Perioperative Mortality
5-6	A	15-50 yr	10%
7-9	B	Candidate for transplant	30%
10-15	C	1-3 mo	82%

Score: 5-6 (Child's A), 7-9 (Child's B), 10-15 (Child's C)
*Note: Child's classification is rarely used for shunting (TIPS or other surgical shunts), but is still useful to quantitate the severity of cirrhosis

Complications

- hematologic changes in cirrhosis
  - pancytopenia from hypersplenism: platelets first, then WBC, then hemoglobin
  - decreased clotting factors resulting in elevated INR
  - relationship of INR to bleeding tendency is controversial; some patients may be hypocoagulable, others may be hypercoagulable
- variceal bleeds
  - 1/2 of patients with cirrhosis have gastroesophageal varices and 1/3 of these develop hemorrhage with an overall mortality of >30%
  - HVPG ≥10 mmHg is the strongest predictor of variceal development
  - treatment: resuscitation, antibiotic prophylaxis, vasoactive drugs (e.g. octreotide IV) combined with endoscopic band ligation or sclerotherapy, TIPS
- renal failure in cirrhosis
  - classifications
    - pre-renal (usually due to overdiuresis)
    - acute tubular necrosis
    - HRS
      - type I: sudden and acute renal failure (rapid doubling of creatinine over 2 wk)
      - type II: gradual increase in creatinine with worsening liver function (creatinine doubling over years)
    - HRS can occur at any time in severe liver disease, especially after:
      - overdiuresis or dehydration, such as diarrhea, vomiting, etc.
      - GI bleed
      - sepsis

Cirrhosis Complications

VARICES
Varices
Ascites/Anemia
Renal failure (HRS)
Infection
Coagulopathy
Encephalopathy
Sepsis

Usual causes of death in cirrhosis: renal failure (hepatorenal syndrome), sepsis, GI bleed, or HCC

Hepatorenal Syndrome vs. Pre-Renal Failure – Difficult to Differentiate
Similar blood and urine findings
Urine sodium: very low in hepatorenal; low in pre-renal
IV fluid challenge: giving volume expanders improves pre-renal failure, but not HRS

Hepatopulmonary Syndrome

Clinical Triad
Liver disease
Increased alveolar-arterial gradient while breathing room air
Evidence for intrapulmonary vascular abnormalities

Fibrosis may regress and disappear if cause of liver injury is treated or resolves

- treatment for HRS (generally unsuccessful at improving long-term survival)
  - for type I HRS: octreotide + midodrine + albumin (increases renal blood flow by increasing systemic vascular resistance)
  - definitive treatment is liver transplant

- hepatopulmonary syndrome
  - majority of cases due to cirrhosis, though may be due to other chronic liver diseases, such as non-cirrhotic portal HTN
  - thought to arise from:
    - ventilation-perfusion mismatch (intrapulmonary shunting and limitation of oxygen diffusion)
    - failure of damaged liver to clear circulating pulmonary vasodilators and/or increased production of vasodilators by liver
  - clinical features
    - hyperdynamic circulation with cardiac output >7 L/min at rest and decreased pulmonary + systemic resistance (intrapulmonary shunting)
    - dyspnea, platypnea (increase in dyspnea in upright position, improved by recumbency), and orthodeoxia (desaturation in the upright position, improved by recumbency)
    - diagnosis via contrast-enhanced echocardiography: inject air bubbles into peripheral vein; air bubbles appear in left ventricle after third heartbeat (normal = no air bubbles; in ventricular septal defect, air bubbles seen <3 heart beats)
    - only proven treatment is liver transplantation

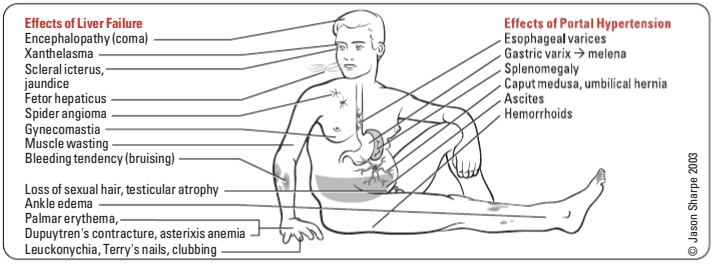

Figure 14. Clinical features of liver disease

Hepatocellular Carcinoma

- see General Surgery and Thoracic Surgery, GS53

Liver Transplantation

- see General Surgery and Thoracic Surgery, GS54

Portal Hypertension

Definition

- pressure gradient between hepatic vein pressure and wedged hepatic vein pressure (corrected sinusoidal pressure) >5 mmHg

Pathophysiology

- 3 sites of increased resistance (remember pressure = flow x resistance)
  - pre-sinusoidal (e.g. portal vein thrombosis, schistosomiasis, sarcoidosis)
  - sinusoidal (e.g. cirrhosis, alcoholic hepatitis)
  - post-sinusoidal (e.g. right-sided heart failure, hepatic vein thrombosis, veno-occlusive disease, constrictive pericarditis)

Complications

- GI bleeding from varices in esophagus, less commonly in stomach, even less frequently from portal hypertensive gastropathy
- ascites
- hepatic encephalopathy
- thrombocytopenia
- renal dysfunction
- sepsis
- arterial hypoxemia

Portal Hypertension

Signs
- Esophageal varices
- Melena
- Splenomegaly
- Ascites
- Hemorrhoids

Management
- β-blockers
- Nitrates
- Shunts (e.g. TIPS)

Treatment
- non-selective β-blockers (propranolol, nadolol, carvedilol) decrease risk of bleeding from varices; PREDESCI trial (Lancet 2019;393:1597-1608) showed that non-selective β-blockers in cirrhotic patients with portal hypertension lowers risk of decompensation (particularly ascites)
- TIPS: to decrease portal venous pressure
  - radiologically inserted stent between portal and hepatic vein via transjugular vein catheterization and percutaneous puncture of portal vein
  - can be used to stop acute variceal bleeding or prevent rebleeding or treat ascites
  - complications: hepatic encephalopathy, right sided heart failure, deterioration of hepatic function
  - contraindicated with severe liver dysfunction, uncontrolled hepatic encephalopathy, and congestive heart failure

Hepatic Encephalopathy

Definition
- spectrum of potentially reversible neuropsychiatric syndromes secondary to hepatic insufficiency and/or portosystemic shunting, diagnosed after ruling out other causes for symptoms (e.g. structural/metabolic)

Pathophysiology
- portosystemic shunt around hepatocytes and decreased hepatocellular function increase level of systemic toxins (believed to be ammonia from gut, mercaptans, fatty acids, amino acids) which go to the brain

Precipitating Factors
- nitrogen load (GI bleed, protein load from food intake, renal failure, constipation)
- drugs (narcotics, CNS depressants)
- electrolyte disturbance (hypokalemia, alkalosis, hypoxia, hypovolemia)
- infection (SBP)
- deterioration in hepatic function or superimposed liver disease
- spontaneous portosystemic shunts (e.g. splenorenal shunts) or intentional portosystemic shunts (e.g. TIPS)

Stages
A. minimal hepatic encephalopathy (diagnosed with specialized cognitive testing)
B. overt hepatic encephalopathy (stages I to IV)
- I: apathy, restlessness, reversal of sleep-wake cycle, slowed intellect, impaired computational abilities, impaired handwriting
- II: asterixis, lethargy, drowsiness, disorientation
- III: stupor (rousable), hyperactive reflexes, extensor plantar response (positive Babinski sign)
- IV: coma (response to painful stimuli only)

Investigations
- clinical diagnosis: supported by laboratory findings and exclusion of other neuropsychiatric diseases
- rule out:
  - non-liver-related neuropsychiatric disease in a patient with liver problems (e.g. EtOH withdrawal or intoxication, sedatives, subdural hematoma, metabolic encephalopathy)
  - causes of metabolic encephalopathy (e.g. renal failure, respiratory failure, severe hyponatremia, hypoglycemia)
- characteristic EEG findings: diffuse (non-focal), slow, high amplitude waves
- serum ammonia levels increased, but not often necessary to measure in routine clinical use

Treatment
- treat underlying precipitating factors
- decrease generation of nitrogenous compounds
  - routine protein restriction is no longer recommended given patients generally have concurrent malnutrition and muscle wasting; however, vegetable protein (as opposed to animal protein) may help reduce risk of encephalopathy
  - lactulose or lactitol: titrated to achieve 2-3 soft stools/d
    - prevents diffusion of NH_3 (ammonia) from the colon into blood by lowering pH and forming non-diffusible NH_4^+(ammonium)
    - serves as a substrate for incorporation of ammonia by bacteria, promotes growth in bowel lumen of bacteria which produce minimal ammonia
    - also acts as a laxative to eliminate nitrogen-producing bacteria from colon
- oral rifaximin for both acute treatment and maintenance therapy has high level evidence for efficacy
- best acute treatment in patients who cannot take medication orally is lactulose or lactitol enemas

Precipitating Factors for Hepatic Encephalopathy

HEPATICS
Hemorrhage in GI tract/Hypokalemia
Excess dietary protein
Paracentesis
Alkalosis/Anemia
Trauma
Infection
Colon surgery
Sedatives

A Randomized, Double-Blind, Controlled Trial Comparing Rifaximin plus Lactulose with Lactulose Alone in Treatment of Overt Hepatic Encephalopathy
American J Gastroenterol 2013;108:1458-1463
Study: Prospective double-blinded RCT.
Purpose: Efficacy and safety of rifaximin plus lactulose vs. lactulose alone for treatment of overt HE.
Results: Of the patients, 48 (76%) in group A (lactulose plus rifaximin 1200 mg/d, n=63) compared with 29 (50.8%) in group B (lactulose plus placebo, n=57) had complete reversal of HE (P<0.004). There was a significant decrease in mortality after treatment with lactulose plus rifaximin vs. lactulose plus placebo (23.8% vs. 49.1%, P<0.05). There were significantly more deaths in group B because of sepsis (group A vs. group B: 7:17, P=0.01), whereas there were no differences because of GI bleed (group A vs. group B: 4:4, P=nonsignificant (NS)) and HRS (group A vs. group B: 4:7, P=NS). Patients in the lactulose plus rifaximin group had shorter hospital stay (5.8±3.4 vs. 8.2±4.6 d, P=0.001).
Conclusion: Combination of lactulose plus rifaximin is more effective than lactulose alone in the treatment of overt HE.

Ascites

Definition
- accumulation of excess fluid in the peritoneal cavity

Etiology

Table 23. Serum-Ascites Albumin Gradient in the Evaluation of Ascites

Serum [Alb] – Ascitic [Alb] >11 g/L (1.1 g/dL) Portal Hypertension Related	Serum [Alb] – Ascitic [Alb] <11 g/L (1.1 g/dL) Non-Portal Hypertension Related
Cirrhosis/severe hepatitis	Peritoneal carcinomatosis
Chronic hepatic congestion (right heart failure, Budd-Chiari)	Peritoneal TB
Massive liver metastases	Pancreatic disease
Portal vein thrombosis	Serositis
Idiopathic portal fibrosis	Nephrotic syndrome*

* In nephrotic syndrome: decreased serum [Alb] to begin with, therefore gradient not helpful

Pathophysiology
- key factor in pathogenesis is increased sodium (and water) retention by the kidney for reasons not fully understood. Theories include:
  - underfill hypothesis
  - overfill hypothesis
  - peripheral arterial vasodilation theory (most popular): as portal hypertension develops in cirrhosis, production of local mediators such as nitric oxide leads to splanchnic arterial vasodilation, ultimately pulling blood away from the systemic circulation and resulting in reduced effective arterial volume, which causes compensatory sodium and fluid retention by the kidneys (i.e. circulatory volume is increased, as per the overfill hypothesis, but effective volume is decreased as per the underfill hypothesis)

Underfill Hypothesis
First step in ascites formation is increased portal pressure and low oncotic pressure (e.g. low serum albumin) driving water out of the splanchnic portal circulation into abdominal cavity; the resulting decreased circulating volume causes secondary sodium retention by the kidney

Overfill Hypothesis
Cirrhosis directly causes increased sodium retention by the kidney in the absence of hypovolemia and ascites arises secondarily

Diagnosis
- abdominal U/S
- physical exam (clinically detectable when >500 mL)
  - bulging flanks, flank dullness, shifting dullness, fluid-wave test positive
  - most sensitive symptom: ankle swelling

Investigations
- diagnostic paracentesis
  - 1st aliquot: cell count and differential
  - 2nd aliquot: chemistry (especially albumin, but also total protein; amylase if pancreatitis; TG and chylomicrons if turbid and suspect chylous ascites)
  - 3rd aliquot: C&S, Gram stain
  - 4th aliquot: cytology (usually positive in peritoneal carcinomatosis)

Serum Ascites Albumin Gradient (SAAG) = serum albumin – ascites albumin
>11 g/L portal HTN
Ascitic fluid total protein >25 g/L, suggests cardiac portal hypertension
Ascitic fluid total protein <25 g/L, suggests cirrhosis portal hypertension
<11 g/L unrelated to portal HTN

Treatment
- diuretic-sensitive ascites
  - Na^+ restriction (daily sodium intake <2 g)
  - no need for fluid restriction unless significant hyponatremia (e.g. Na^+<120-125 mmol/L)
  - diuretics: spironolactone, furosemide
  - aim for weight loss 0.5-1 kg/d, more if concomitant peripheral edema (which is mobilized quicker than ascitic fluid); overly rapid weight loss increases risk of renal failure
  - if target weight loss is not achieved and there are no complications, increase dose to achieve target while monitoring for complications
- refractory ascites (diuretics are inadequate or not tolerated)
  - therapeutic paracentesis with IV albumin
  - TIPS in an appropriate patient (no contraindications) with potential transplant-free survival advantage
  - liver transplantation should be considered in every case, since development of ascites in patients with cirrhosis is associated with a high 2 yr mortality

Complication: Primary/Spontaneous Bacterial Peritonitis
- primary/SBP
  - complicates ascites, but does not cause it (occurs in 10% of cirrhotic ascites); higher risk in patients with GI bleed
  - 1/3 of patients are asymptomatic, thus do not hesitate to do a diagnostic paracentesis in ascites even if no clinical indication of infection
  - fever, chills, abdominal pain, ileus, hypotension, worsening encephalopathy, acute kidney injury
  - Gram-negatives compose 70% of pathogens: *E. coli* (most common), *Streptococcus, Klebsiella*

- diagnosis
  - absolute neutrophil count in peritoneal fluid >0.25x10^9 cells/L (250 cells/mm ^{3})
  - Gram stain positive in only 10-50% of patients
  - culture positive in <80% of patients (not needed for diagnosis)
- prophylaxis: consider in patients with:
  - cirrhotic with GI bleed: ceftriaxone IV daily or norfloxacin BID x 7 d
  - previous episode of SBP: long-term prophylaxis with daily norfloxacin or TMP-SMX
- treatment
  - IV ABx (cefotaxime 2 g IV q8h or ceftriaxone 2 g IV daily is the treatment of choice for 5 d; modify if response inadequate or culture shows resistant organisms)
  - IV albumin (1.5 g/kg at time of diagnosis and 1 g/kg on day 3) decreases mortality by lowering risk of acute renal failure

Biliary Tract

Jaundice

• see *Table 2, G6* and *Figures 15 and 16*

Definition
• yellowing of the skin, sclera, and/or mucous membranes due to abnormal deposition of pigmented bilirubin

Signs and Symptoms
• dark urine, pale stools: suggests that bilirubin elevation is from direct fraction
• pruritus: suggests chronic disease, cholestasis
• abdominal pain: suggests biliary tract obstruction from stone or pancreatic/biliary tumour (obstructive jaundice)
• painless jaundice in the elderly: think of pancreatic cancer
• kernicterus: rarely seen in adults due to maturation of blood brain barrier

Investigations
• blood work: CBC, bilirubin (direct and total), liver enzymes (AST, ALT, ALP, GGT), liver function tests (INR/PT, PTT, albumin), ± amylase/lipase
• U/S or CT for evidence of bile duct obstruction (e.g. bile duct dilation)
• more detailed evaluation of bile duct ± surrounding structures like pancreas:
  - MRCP: non-invasive
  - EUS: sensitive for stones and pancreatic tumours
  - ERCP: invasive, most accurate, allows for therapeutic intervention
  - PTC: if ERCP fails (endoscopic access not possible)

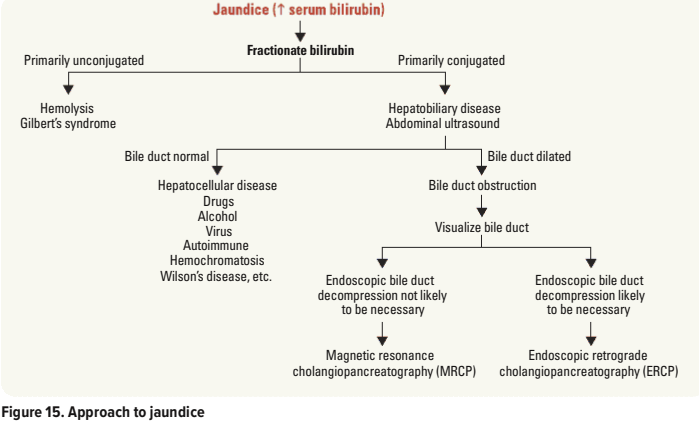

Figure 15. Approach to jaundice

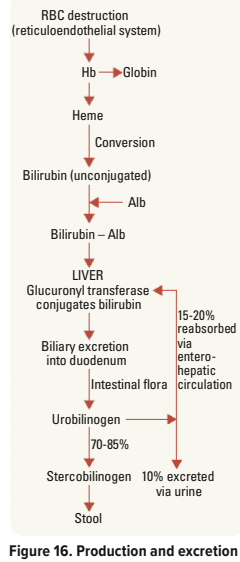

Figure 16. Production and excretion of bilirubin

Gilbert's Syndrome

Definition
- hereditary hyperbilirubinemia due to a deficiency of glucuronyl transferase characterized by repeat episodes of mild asymptomatic jaundice

Etiology/Epidemiology
- some patients have decreased hepatobiliary uptake
- affects 7% of population, especially males
- autosomal dominant, 70% due to a mutation in the UGT gene

Clinical Features
- presents in teens-20s, often an incidental finding
- only manifestation is intermittent jaundice with increased serum unconjugated bilirubin developing most characteristically while fasting, or at times of acute illness; no other clinical implications

Treatment
- reassurance (entirely benign)

Gilbert's Syndrome vs. Crigler-Najjar Syndrome
Gilbert's Syndrome: mild decrease in glucuronyltransferase activity
Crigler-Najjar Syndrome: complete deficiency of glucuronyltransferase

Primary Sclerosing Cholangitis

Definition
- inflammation, fibrosis, and stricturing of biliary tree (intra- and/or extrahepatic bile ducts) from scarring

Etiology
- primary/idiopathic (most common)
  - associated with IBD, more commonly UC, in up to 70-80% of patients (usually male) with PSC
- secondary sclerosing cholangitis (less common)
  - long-term choledocholithiasis
  - cholangiocarcinoma
  - surgical/traumatic injury (iatrogenic)
  - contiguous inflammatory process
  - post-ERCP
  - associated with HIV/AIDS ("HIV cholangiopathy")
  - IgG4-related disease
  - critical illness

Signs and Symptoms
- often insidious, may present with fatigue and pruritus
- may present with signs of episodic bacterial cholangitis secondary to biliary obstruction
- may present with jaundice, hepatomegaly, splenomegaly, excoriations secondary to pruritus

Investigations
- increased ALP (hallmark), less often increased bilirubin
- mildly increased AST, usually <300 U/L
- p-ANCA (30-80%), elevated IgM (40-50%)
- MRCP and ERCP shows narrowing and dilatations of bile ducts that may result in "beading," both intrahepatic and extrahepatic bile ducts
  - if intrahepatic narrowing only, do anti-mitochondrial antibody to rule out PBC
- consider livery biopsy if suspecting small duct variant (accounts for approximately 10% of cases of PSC)

Complications
- repeated bouts of cholangitis may lead to complete biliary obstruction with resultant secondary biliary cirrhosis and hepatic failure
- increased incidence of cholangiocarcinoma (10-15%): difficult to diagnose and treat
- increased incidence of colon cancer in those with concurrent IBD

Treatment
- image bile duct (MRCP) at least annually for early detection of cholangiocarcinoma (controversial)
- endoscopic sphincterotomy, biliary stent in selected cases of dominant common bile duct stricture
- ABx for cholangitis
- suppurative cholangitis requires emergency drainage of pus in common bile duct
- liver transplantation appears to be the best treatment for advanced sclerosing cholangitis (>90% 1 yr survival; mean follow-up time from diagnosis to need for transplant is 10 yr)
- ursodiol: previously recommended, but studies suggest that it increases mortality if taken in high doses

Prognosis
- unfavourable regardless of treatment
- mean survival after diagnosis remains 4-10 yr

Primary Biliary Cholangitis (formerly Primary Biliary Cirrhosis)

Definition
- chronic inflammation and fibrous obliteration of intrahepatic bile ductules

Etiology/Epidemiology
- likely autoimmune (associated with Sjögren's syndrome, scleroderma, CREST syndrome (calcinosis, Raynaud's phenomenon, esophageal dysfunction, sclerodactyly, telangiectasia), RA, thyroiditis)
- affects mainly middle-aged women (M:F=1:9)

Signs and Symptoms
- often asymptomatic
- initial symptoms: pruritus, fatigue
- chronic: jaundice and melanosis (darkening skin) and other signs of cholestasis
- end-stage: hepatocellular failure, portal HTN, ascites
- high incidence of osteoporosis

Investigations
- increased ALP, GGT; bilirubin rises in later stage
- positive anti-mitochondrial antibodies (AMA; 95% specificity and sensitivity)
- elevated IgM
- increased serum cholesterol (mild increase in LDL, larger increase in HDL)
  - may have: xanthelasmas, xanthomas
- liver biopsy confirms diagnosis and stages severity but is usually not required - elevated ALP for >6 mo and positive AMA are diagnostic
- normal bile duct on MRCP rules out bile duct obstruction which can mimic PBC
- "overlap" syndromes with autoimmune cholangitis, autoimmune hepatitis, sclerosing cholangitis are possible

Treatment
- drugs that treat the underlying disease:
  - ursodeoxycholic acid (UDCA ; first line treatment)
  - obeticholic acid (if inadequate response to ursodiol)
- cholestyramine (for pruritus and hypercholesterolemia)
- calcium and vitamin D for low bone density; bisphosphonates if osteoporosis severe
- repeated monitoring of liver enzymes and LFTs (q 3-6 mo), TSH (annually), and BMD (q 2-4 yr)
- ensure vaccines are updated (notably HAV & HBV); avoid EtOH, smoking
- liver transplant if disease severe, progressive

Prognosis
- can be fatal, although not all asymptomatic patients show progression
- treatment improves prognosis - response to treatment with UDCA (normalization or near-normalization of ALP) is associated with survival comparable to age- and sex-matched controls

Table 24. Primary Sclerosing Cholangitis vs. Primary Biliary Cholangitis

	Primary Sclerosing Cholangitis	Primary Biliary Cholangitis
Predominant Gender	Male	Female
Associated Comorbidities	IBD, especially UC	Other autoimmune disorders (Sjögren's, CREST, RA)
Affected Ducts	Both intra- and extrahepatic	Intrahepatic only
Investigations	ERCP/MRCP (narrowing and dilatations of ducts visualized)	Anti-mitochondrial antibodies, IgM, increased lipids, liver biopsy (absence of duct narrowing on ERCP)

MRCP/ERCP
Absence of narrowing in PBC
Narrowing of intra- and extrahepatic ducts in PSC

Endoscopic or Surgical Step-Up Approach for Infected Necrotising Pancreatitis: A Multicentre Randomised Trial
Lancet 2018;391:51-58
Purpose: To compare the outcomes of endoscopic vs. the standard surgical removal of infected necrotising pancreatitis.
Study: RCT.
Population: 98 patients with pancreatic or extrapancreatic necrosis were randomized to either endoscopic removal or surgical removal of the infected necrosis.
Outcomes: Major complications and death at 6 mo follow-up.
Results: The primary endpoints of mortality and major complications were the same in the two groups, but the endoscopic group had shortened hospital stays and less pancreatic fistulae.
Conclusions: Three points are worth emphasizing: (1) necrotising pancreatitis is a severe disease: about 15% in each group died; (2) it is best to wait at least 4 wk after the necrosis has developed to allow it to be encapsulated; (3) the management of severe acute pancreatitis should include experts skilled in therapeutic endoscopy.

Biliary Colic, Cholecystitis

- see General Surgery and Thoracic Surgery, GS56

Ascending Cholangitis

- see General Surgery and Thoracic Surgery, *Acute Cholangitis*, GS58

Definition
- infection of the biliary tree

Etiology
- stasis in the biliary tract due to obstruction or stricture
- bacteria
  - *E. coli, Klebsiella, Enterobacter, Enterococcus*
  - coinfection with *Bacteroides* and *Clostridia* can occur

Charcot's Triad
RUQ pain
Fever
Jaundice

Reynolds' Pentad
Charcot's triad
Hypotension
Altered mental status

Signs and Symptoms
- Charcot's triad: fever, RUQ pain, jaundice (50-70%)
- Reynolds' pentad in patients with suppurative cholangitis: fever, RUQ pain, jaundice, hypotension, altered mental status

Investigations
- evidence of systemic inflammation (increased WBC, increased CRP)
- usually increased ALP and bilirubin, ALT variably elevated (can be markedly increased if acute obstruction from common bile duct (CBD) stone)
- blood culture
- abdominal U/S: CBD dilation, stricture, stones

Treatment
- most important is drainage, ideally via ERCP; perform by percutaneous biliary or by surgical routes (least often) if ERCP not possible
- antibiotic therapy: broad spectrum to cover Gram-negatives, Enterococcus, and anaerobes (especially if CBD manipulation); no clear consensus on antibiotic choice but consider:
  - ampicillin + sulbactam or piperacillin/tazobactam
  - metronidazole + 3rd generation cephalosporin (e.g. ceftriaxone) or fluoroquinolone (e.g. ciprofloxacin or levofloxacin)
  - carbapenem monotherapy (e.g. imipenem or meropenem)

Prognosis
- good with effective drainage and ABx in mild to moderate cases
- high mortality (~50%) in patients with Reynolds' pentad

Pancreas

Pancreatic Enzyme Abnormalities

Causes of Increased Serum Amylase
- pancreatic disease
  - pancreatitis, pancreatic duct obstruction (e.g. ampullary cancer), pseudocyst, abscess, ascites, trauma, cancer
- non-pancreatic abdominal disease
  - biliary tract disease, bowel obstruction/ischemia, perforated or penetrating ulcer, ruptured ectopic pregnancy, aneurysm, chronic liver disease, peritonitis
- non-abdominal disease
  - cancer (lung, ovary, esophagus, etc.), salivary gland lesions, bulimia, renal transplant/insufficiency, burns, ketoacidosis
  - macroamylasemia

Causes of Increased Serum Lipase
- pancreatic disease: same as above
- non-pancreatic abdominal disease (mild elevations only): same as above
- non-abdominal disease
  - macrolipasemia
  - renal failure

Pancreatic Enzymes

TALC
Trypsin
Amylase
Lipase
Chymotrypsin

When serum amylase >5x normal, the cause is almost always pancreatitis or renal disease

Acute Pancreatitis

Etiology (most common are alcohol and gallstones)
- **I**diopathic: thought to be hypertensive sphincter or microlithiasis
- **G**allstones (45%)
- **E**thanol (35%)
- **T**umours: pancreas, ampulla, choledochocele
- **S**corpion stings
- **M**icrobiological
  - bacterial: *Mycoplasma, Campylobacter*, TB, *M. avium intracellulare, Legionella, Leptospira*
  - viral: mumps, rubella, varicella, viral hepatitis, CMV, EBV, HIV, Coxsackie virus, echovirus, adenovirus
  - parasites: ascariasis, clonorchiasis, echinococcosis
- **A**utoimmune: IgG4-related disease, SLE, *polyarteritis nodosa* (PAN), CD
- **S**urgery/trauma
  - manipulation of sphincter of Oddi (e.g. ERCP), post-cardiac surgery, blunt trauma to abdomen, penetrating peptic ulcer
- **H**yperlipidemia (TG >11.3 mmol/L; >1000 mg/dL), hypercalcemia, hypothermia
- **E**mboli or ischemia
- **D**rugs/toxins
  - azathioprine, mercaptopurine, furosemide, estrogens, methyldopa, H_2-blockers, valproic acid, ABx, acetaminophen, salicylates, methanol, organophosphates, steroids (controversial)

When thinking about the causes of acute pancreatitis remember: **I GET SMASHED,** but vast majority due to gallstones or ethanol

Pathophysiology
- activation of proteolytic enzymes within pancreatic cells, starting with trypsin, leading to local and systemic inflammatory response
- in gallstone pancreatitis, this is due to mechanical obstruction of the pancreatic duct by stones
- in ethanol-related pancreatitis, pathogenesis is unknown
- in rare genetic diseases, mutations prevent the physiological breakdown of trypsin required normally to stop proteolysis (e.g. mutant trypsin in hereditary pancreatitis or mutation in *SPINK1* gene, which normally inhibits activated trypsin); may be model for ethanol-related pancreatitis

Pathology
- mild (interstitial)
  - peri-pancreatic fat necrosis
  - interstitial edema
- severe (necrotic)
  - extensive peri-pancreatic and intra-pancreatic fat necrosis
  - parenchymal necrosis and hemorrhage → infection in 60%
  - release of toxic factors into systemic circulation and peritoneal space (causes multi-organ failure)
- severity of clinical features may not always correlate with pathology
- 3 phases
  - local inflammation + necrosis → hypovolemia
  - systemic inflammation in multiple organs, especially in lungs, usually after IV fluids given → pulmonary edema
  - local complications >2 wk after presentation → fluid collection (pseudocyst) or tissue collection (necrosis), sterile or infected

Cullen's Sign
Sensitive, not specific for acute pancreatitis

Grey-Turner's Sign
Flank ecchymosis

Signs and Symptoms
- pain: epigastric, noncolicky, constant
- can radiate to back
- may improve when leaning forward (Inglefinger's sign)
- tender rigid abdomen; guarding
- N/V
- abdominal distention from paralytic ileus
- fever: chemical, not due to infection
- jaundice: compression or obstruction of bile duct
- Cullen's/Grey-Turner's signs
- tetany: transient hypocalcemia
- hypovolemic shock: can lead to renal failure
- acute respiratory distress syndrome
- coma

Increased Amylase
- Sensitive, not specific for acute pancreatitis

Increased Lipase
Higher sensitivity and specificity
Stays elevated longer

Investigations
- increased serum pancreatic enzymes: amylase, lipase (more specific)
- ALT >150 specific for biliary cause
- increased WBC, glucose, low calcium
- imaging: CT most useful for diagnosis and prognosis
  - x-ray: "sentinel loop" (dilated proximal jejunum), calcification, and "colon cut-off sign" (colonic spasm)
  - U/S: useful for evaluating biliary tree (67% sensitivity, 100% specificity)
  - CT scan with IV contrast: most useful when done >1 d after presentation, helpful for diagnosis and prognosis because contrast seen only in viable pancreatic tissue, non-viable areas can be biopsied percutaneously to differentiate sterile from infected necrosis
  - ERCP or MRCP if cause uncertain, assess for duct stone, pancreatic or ampullary tumour, pancreas divisum

Classification
- interstitial edematous vs. necrotizing
- mild, moderate, severe

Prognosis
- usually a benign, self-limiting course, single or recurrent
- occasionally severe leading to:
  - shock
  - pulmonary edema
  - multi-organ dysfunction syndrome
  - GI ulceration due to stress
  - death
    - numerous scales to describe severity: probably most useful is proportion of pancreas not taking up contrast on CT done 48 h after presentation (necrotic pancreas does not take up the contrast dye)
    - presence of organ failure, particularly organ failure that persists >48 h, is associated with worse outcomes

Table 25. Collections in Pancreatitis (Revised 2012 Atlanta Classification)

	Liquid	Solid
Acute	Acute peripancreatic fluid collection (APFC)	Acute necrotic collection (ANC)
Chronic	Pancreatic pseudocyst	Walled-off necrosis (WON)

All of these collections are classified as infected or not infected

Treatment
- goals (only supportive therapy available)
  1. hemodynamic stability
  2. analgesia
  3. oxygen
  4. stop progression of damage (difficult)
  5. treat local and systemic complications
- antibiotic use in infection (cephalosporins, imipenem), not indicated to prevent infection, although without aspiration/biopsy can be difficult to distinguish infection from non-infected inflammation
- aspirate necrotic areas of pancreas to diagnose infection; drain if infected
- IV fluids (crystalloid or colloid)
  - beware third spacing of fluid, monitor urine output carefully
- NG suction (lets pancreas rest) if vomiting, stomach very dilated
- endoscopic sphincterotomy if severe gallstone pancreatitis (i.e. cholangitis or ongoing obstruction)
- nutritional support: NJ feeding tube or TPN if cannot tolerate enteric feeds
  - recent evidence supports NG enteral (or oral if feasible) feeds
- no benefit: glucagon, atropine, aprotinin, H_2-blockers, peritoneal lavage
- follow clinically and CT or U/S to exclude complications
- chief role of invasive intervention is to drain fluid collection, excise necrotic tissue (necrosectomy), especially indicated if pseudocyst or walled-off necrosis is infected
  - try to delay for >2 wk to allow demarcation between viable and necrotic tissue, better done endoscopically or radiologically, rather than surgically if technically possible

Late Complications
- pseudocysts: follow if asymptomatic, drain if symptomatic or growing
  - drain preferably: endoscopic, percutaneous under radiological guidance, surgical if less invasive methods fail
- infected necrosis/abscesses: ABx + percutaneous drainage, endoscopic preferable to surgical
- bleeding: (1) gastric varices if splenic vein thrombosis, (2) pseudoaneurysm of vessels in areas of necrosis, especially splenic artery, (3) duodenal ulcer related to compression of duodenum by enlarged pancreas
- splenic and portal vein thrombosis: no effective therapy described, anticoagulation not proven, hazardous
- rare: DM, pancreatic duct damage

Gallstones only cause acute pancreatitis (not chronic pancreatitis)

Symptoms of Chronic Pancreatitis
- Abdominal pain
- Diabetes
- Steatorrhea

Etiology = Almost Always Alcohol

Treatment
- EtOH abstinence
- Pancreatic enzyme replacement
- Analgesics
- Pancreatic resection if ductular blockage

Chronic Pancreatitis

Definition
- irreversible damage to pancreas characterized by
  1. pancreatic cell loss (from necrosis)
  2. inflammation
  3. fibrosis

Etiology/Pathophysiology
- **T**oxic-metabolic
  - EtOH (most common)
    - causes a larger proportion (>90%) of chronic pancreatitis than acute pancreatitis
    - changes composition of pancreatic juice (e.g. increase viscosity)
    - decreases pancreatic secretion of pancreatic stone protein (lithostathine), which normally solubilizes calcium salts
      - precipitation of calcium within pancreatic duct results in duct and gland destruction
    - toxic effect on acinar and duct cells - directly or via increasing free radicals
    - acinar cell injury leads to cytokine release, which stimulates pancreatic stellate cells to form collagen (leading to fibrosis)
    - varying degrees of ductular dilatation, strictures, protein plugs, calcification
    - no satisfactory theory to explain why only a minority of individuals with EtOH use disorder develop pancreatitis
  - smoking
  - hypercalcemia
  - hypertriglyceridemia
  - medications
- **I**diopathic
- **G**enetic
- **A**utoimmune pancreatitis/steroid-responsive pancreatitis (e.g. IgG4-related disease)
- **R**ecurrent acute pancreatitis/severe acute pancreatitis
- **O**bstructive (e.g. pancreas divisum, ampullary stenosis)

Signs and Symptoms
- early stages
  - recurrent attacks of severe abdominal pain (upper abdomen and back)
  - chronic painless pancreatitis: 10%
- late stages: occurs in 15% of patients
  - steatorrhea (maldigestion) when >90% of function is lost
  - diabetes, calcification, jaundice, weight loss, pseudocyst, ascites, GI bleed

When to Call the Surgeon in Acute Pancreatitis?
Endoscopic Transgastric vs. Surgical Necrosectomy for Infected Necrotizing Pancreatitis: A Randomized Trial JAMA 2012;307:1053-1061
Once it was recognized that severe acute (necrotizing) pancreatitis had a terrible prognosis because of an exuberant inflammatory response leading to multiorgan failure, pancreatectomy was attempted. However, contrary to the expected favourable results, clinical experience has shown that surgical pancreatectomy is usually not helpful, perhaps because once the inflammatory cascade starts, it persists as a self-perpetuating cycle. The problems caused by acute pancreatitis can be thought of as widespread burn initiated by inflammation in the pancreas, but having little to do with ongoing problems within the pancreas itself. Studies suggest that the only compelling indication for surgery is infected necrotizing pancreatitis not responding to ABx. As predicted, without removal of such infected pancreatic tissue, death is likely from sepsis.
In this recent randomized trial, transgastric necrosectomy, an endoscopic technique that also removes infected necrotic pancreatic tissue, reduced both a composite endpoint of major pancreatitis complications (especially new onset organ failure) and the pro-inflammatory response (as measured by serum IL-6 levels) to a greater extent than surgical necrosectomy. Of course, not all necrotic collections are in areas amenable to endoscopic intervention, and the advice of an experienced surgeon should always be welcomed in severe acute pancreatitis, but the role of surgery in this previously considered surgical disease is rapidly diminishing.

Investigations
- laboratory
  - increase in serum glucose
  - increase in serum ALP, less commonly bilirubin (jaundice)
  - serum amylase and lipase usually normal
  - stool elastase is low in steatorrhea
- abdominal x-ray: pancreatic calcifications
- U/S or CT: calcification, dilated pancreatic ducts, pseudocyst
- MRCP or ERCP: abnormalities of pancreatic ducts-narrowing and dilatation
- EUS: abnormalities of pancreatic parenchyma and pancreatic ducts, most sensitive test
- 72 h fecal fat test: measures exocrine function, fecal elastase preferable
- secretin test: gold standard, measures exocrine function but difficult to perform, unpleasant for patient, expensive

Treatment
- most common problem is pain, difficult to control
- general management
  - complete abstinence from EtOH
  - enzyme replacement may help pain by resting pancreas via negative feedback
  - analgesics
  - celiac ganglion blocks
  - time: pain decreases with time as pancreas "burns out"
- endoscopy: sphincterotomy, stent if duct is dilated, remove stones from pancreatic duct
- surgery: drain pancreatic duct (pancreaticojejunostomy) if duct is dilated (more effective than endoscopy); resect pancreas if duct is contracted
- steatorrhea
  - pancreatic enzyme replacement
  - neither endoscopy nor surgery can improve pancreatic function

Autoimmune Pancreatitis

- most commonly presents as a mimicker of pancreatic cancer (pancreatic mass detected because of jaundice ± abdominal pain)

Investigations
- histology: lymphocyte and plasma cell infiltration of pancreas
- imaging: focal or diffuse enlargement of pancreas on CT or MRI, sausage-shaped, low density rim around pancreas
- serology: increased serum IgG4 in type 1
- other organ involvement: sialadenitis, retroperitoneal fibrosis, biliary duct narrowing, nephritis

Treatment
- responds to prednisone
- for refractory patients, consider immunomodulators (azathioprine, mycophenolate mofetil, methotrexate) or rituximab

Clinical Nutrition

Determination of Nutritional Status

Challenging to Differentiate Markers of Malnutrition from Markers of Disease
- most important feature in assessing the need for nutritional support is weight loss (expressed as change in body mass index (kg/m^2))
- Subjective Global Assessment divides nutritional status into A) adequately nourished, B) mild or moderate malnutrition, and C) severe malnutrition in order to identify those who will benefit from nutritional support
- includes weight change in past 6 mo, weight change in past 2 wk, dietary intake change, current dietary intake, GI symptoms, functional capacity, effect of disease on nutritional requirements and physical examination, including loss of subcutaneous fat/muscles wasting/edema/ascites

Table 26. Small Bowel Nutrient Absorption

	Fe^{3+}	CHO	Proteins, Lipids Na^+, H_2O	Bile Acids	Vitamin B_{12}
Duodenum	+++	+++	+++	+	
Jejunum	+	+	++	+	+
Ileum	+	+	++	+++	+++

Determining Nutritional Requirements
- calories: total energy expenditure (TEE) = resting energy expenditure (REE) x stress factor (e.g. 1.7 for burns) usually works out to be 25-35 kcal/kg depending on how disease affects metabolism, with IV nutrition delivered as about 60% carbohydrate, 40% fat. Current trend is to provide fewer calories ("permissive underfeeding"), especially in ICU, to prevent hyperglycemia
- protein: 1-2 g/kg/d, depending on effect of disease on protein metabolism. In disease, a greater proportion of energy expenditure comes from protein than in health
- electrolytes, minerals, and vitamins also required

Indications for Aggressive Nutritional Support:
- inability to meet nutritional needs; logical, but convincing evidence from literature not available for ICU and other acute illnesses
- evidence that nutritional support improves outcome available for (1) short bowel syndrome (home TPN), (2) before major abdominal or thoracic surgery if there is substantial malnutrition, (3) before therapy for cancer of esophagus, head, and neck, (4) decompensated alcoholic liver disease, (5) pancreatitis (acute and chronic). May be helpful for other indications also, but insufficient data
- nutritional support at best prevents protein loss but usually no gain

Enteral Nutrition

Definition
- EN (tube feeding) is a way of providing food through a tube placed in the stomach or the small intestine
  - nasogastric (NG), or nasojejunal (NJ) if nutritional support required for brief time; percutaneous endoscopic gastrostomy ("G-tube" or "PEG tube")/percutaneous endoscopic jejunostomy (J-tube) if nutritional support required for more than 1 mo
- tubes can be placed endoscopically, radiologically, or surgically

Most Common Indications for Artificial Nutrition Support
- Preexisting nutritional deprivation
- Anticipated or actual inadequate energy intake by mouth
- Significant multiorgan system disease

Indications
- oral feeding inadequate or contraindicated

Feeds
- polymeric feeds contain whole protein, carbohydrates, fat as a liquid, and may or may not have fibre added
- elemental feeds contain protein (as amino acids), carbohydrates (as simple sugars), and are low in fat content (are therefore high in osmolarity)
- specific diets: low carbohydrate/high fat solution for ventilated patients (carbohydrate has a high respiratory quotient so minimizes carbon dioxide production), high energy, low electrolyte solutions for dialysis patients

Relative Contraindications
- non-functioning gut (e.g. intestinal obstruction, enteroenteral or enterocutaneous fistulae)
- uncontrolled diarrhea
- GI bleeding

Whenever possible, EN is ALWAYS preferable over PN

Complications
- aspiration
- diarrhea
- refeeding syndrome (rare): carbohydrate can stimulate excessive insulin release, leading to cellular uptake and low serum levels of phosphate, magnesium, potassium
- overfeeding syndrome (rare): hypertonic dehydration, hyperglycemia, hypercapnia, azotemia (from excess protein)

Parenteral Nutrition

Definition
- PN is the practice of feeding a person intravenously, bypassing the usual process of eating and digestion

Indications
- short-term (<1 mo)
  - use whenever GI tract not functioning
  - only situations where PN has been well shown to increase survival are after bone marrow transplant and in short bowel syndrome, some evidence for benefit in gastric cancer, but often used in ICU, perioperatively, and in difficult-to-control sepsis
  - preoperative: only useful in severely malnourished (e.g. loss of >15% of pre-morbid weight, serum albumin <28 g/L or <2.8 g/dL), and only if given for ≥2 wk
  - renal failure: PN shown to increase rate of recovery; no increase in survival
  - liver disease: branched chain amino acids may shorten duration of encephalopathy; no increase in survival
  - IBD: PN closes fistulae and heals acute exacerbations of mucosal inflammation, but effect is transient (EN is equally effective)

- some evidence for efficacy, but convincing data not available for:
  - radiation/chemotherapy-induced enteritis
  - AIDS with wasting diarrhea
  - severe acute pancreatitis
- long-term (>1 mo): can be given at home
  - severe untreatable small bowel disease (e.g. radiation enteritis, extensive CD, high output fistulae)
  - following surgical resection of >70% of small bowel (e.g. small bowel infarction)
  - severe motility diseases (e.g. scleroderma affecting bowel)

Hypomagnesemia may be an initial sign of short bowel syndrome in patients who have undergone surgical bowel resection

Relative Contraindications
- functional GI tract available for EN
- active infection; at least until appropriate antibiotic coverage
- inadequate venous access; triple-lumen central venous lines usually prevent this problem

Enteral vs. Parenteral Nutrition for Acute Pancreatitis Cochrane DB Syst Rev 2010;1:CD002837
Purpose: Compare EN vs. TPN on mortality, morbidity, and hospital stay in patients with pancreatitis.
Study Selection: RCTs of TPN vs. EN in pancreatitis.
Results: Eight trials (n=348) were included. EN decreases RR of death (0.50), multiple organ failure (0.55), infection (0.39), and other local complications (0.70). It also decreased hospital stay by 2.37 d.
Conclusion: EN reduces mortality, organ failure, infections, and length of hospital stay in patients with pancreatitis.

Complications of PN
- sepsis: most serious of the common complications
- mechanical pneumothorax from insertion of central line, catheter migration and thrombosis, air embolus
- metabolic: congestive heart failure, hyperglycemia, gallstones, cholestasis, electrolyte abnormalities, micronutrient deficiency

Enteral Nutrition Preferable to Parenteral Nutrition
- fewer serious complications (especially sepsis)
- nutritional requirements better understood
- can supply gut-specific fuels such as glutamine and short chain fatty acids with EN
- nutrients in the intestinal lumen have a trophic effect (prevent atrophy of the gut and pancreas)
- prevents gallstones by stimulating gallbladder motility
- much less expensive

Common Medications

Table 27. Common Drugs Prescribed in Gastroenterology

Class	Generic Drug Name	Trade Name	Dosing	Mechanism of Action	Indications	Contraindications	Side Effects
Proton Pump Inhibitors (H^+K^+-ATPase inhibitors)	omeprazole	Losec®/ Prilosec®	20 mg PO once daily	Inhibits gastric enzymes H^+/K^+-ATPase (proton pump)	Duodenal ulcer, gastric ulcer, NSAID-associated gastric and duodenal ulcers, reflux esophagitis, symptomatic GERD, dyspepsia, Zollinger-Ellison syndrome, eradication of *H. pylori* (combined with ABx)	Hypersensitivity to drug	Dizziness, headache, flatulence, abdominal pain, nausea, rash, increased risk of osteoporotic fracture (secondary to impaired calcium absorption)
	lansoprazole or dexlansoprazole	Prevacid® Dexilant®	Oral therapy: lansoprazole 15-30 mg once daily (before breakfast), dexlansoprazole 30-60 mg once daily (does not need to be taken before breakfast)	Same as above	Same as above	Same as above	Same as above
	pantoprazole	Pantoloc® Protonix®	40 mg PO once daily for UGIB: 80 mg IV bolus then 8 mg/h infusion	Same as above	Same as above and UGIB	Same as above	Same as above
	rabeprazole	Pariet®/ Aciphex®	40 mg PO once daily	Same as above	Same as above	Same as above	Same as above
	esomeprazole	Nexium®	20-40 mg PO once daily	Same as above	Same as above	Same as above	Same as above
Histamine H_2 Receptor Antagonists	ranitidine* *ranitidine drugs recalled in 2019 due to impurity concerns	Zantac®*	300 mg PO once daily or 150 mg BID IV therapy: 50 mg q8 h (but tachyphylaxis a problem)	Inhibits gastric histamine H_2 receptors	Duodenal ulcer, gastric ulcer, NSAID-associated gastric and duodenal ulcers, ulcer prophylaxis, reflux esophagitis, symptomatic GERD; not useful for acute GI bleeds	Hypersensitivity to drug	Confusion, dizziness, headache, arrhythmias, constipation, nausea, agranulocytosis, pancytopenia, depression
	famotidine	Pepcid®	Oral therapy: duodenal/ gastric ulcers: 40 mg qhs GERD: 20 mg BID IV therapy: 20 mg BID	Same as above	Same as above	Same as above	Same as above
Stool Softener	docusate sodium	Colace®	100-400 mg PO once daily, divided in 1-4 doses	Promotes incorporation of water into stool	Relief of constipation	Presence of abdominal pain, fever, N/V	Throat irritation, abdominal cramps, rashes

Table 27. Common Drugs Prescribed in Gastroenterology

Class	Generic Drug Name	Trade Name	Dosing	Mechanism of Action	Indications	Contraindications	Side Effects
Osmotic Laxatives	lactulose	Lactulose Constulose®	Constipation: 15-30 mL PO once daily to BID Encephalopathy: 15-30 mL BID to QID	Poorly absorbed in GI tract and is broken down by colonic bacteria into lactic acid in the colon, increases osmotic colonic contents, increases stool volume	Chronic constipation, prevention, and treatment of portal-systemic encephalopathy	Patients who require a low galactose diet	Flatulence, intestinal cramps, nausea, diarrhea if excessive dosage
	PEG3350	Lax-a-day® RestoraLAX® Golytely®	Constipation: 17 g powder dissolved in 4-8 oz liquid PO once daily	Osmotic agent causes water retention in stool and promotes frequency of stool	Relief of constipation Colonoscopy prep	Hypersensitivity to drug	Abdominal distension, pain, anal pain, thirst, nausea, rigor, tonic-clonic seizures (rare)
	magnesium hydroxide	Milk of Magnesia/ Pedia-Lax®	Constipation (adult): 400 mg/5 mL: 30-60 mL PO qhs	Osmotic retention of fluid which distends the colon and increases peristaltic activity	Relief of constipation	Patients with myasthenia gravis or other neuromuscular disease	Renal impairment Abdominal pain, vomiting, diarrhea
Stimulant Laxatives	senna	Senokot®	Tablets: 1-4 PO qhs Syrup: 10-15 mL PO qhs	Induce peristalsis in lower colon	Constipation	Patients with acute abdomen	Abdominal cramps, discolouration of breast milk, urine, feces, melanosis coli and atonic colon from prolonged use (controversial)
	bisacodyl	Bisacodyl®	5-30 mg PO once daily (start at 10 mg for bowel preparation)	Enteric nerve stimulation and local contact-induced secretory effects Colonic movements	Constipation Preparation of bowel for procedure	GI obstruction Gastroenteritis	Abdominal colic, abdominal discomfort, proctitis (with suppository use), diarrhea
Bulk Laxatives	psyllium	Metamucil®	Start at one heaping tablespoon daily	Increases stool bulk → water retention in stool	Constipation	Hypersensitivity to drug GI obstruction	GI obstruction, diarrhea, constipation, abdominal cramps
Guanylate Cyclase C Agonist	linaclotide	Constella®	75-145 µg once daily	Opens water channels in bowel epithelial cells to add water to stool	Chronic constipation IBS-constipation	Children	Diarrhea
Antidiarrheal Agents	loperamide	Imodium®	Acute diarrhea: 4 mg PO initially, followed by 2 mg after each unformed stool	Acts as antidiarrheal via cholinergic, noncholingeric, opiate, and non-opiate receptor-medicated mechanisms; decreases activity of myenteric plexus	Adjunctive therapy for acute non-specific diarrhea, chronic diarrhea associated with IBD and for reducing the volume of discharge for ileostomies, colostomies, and other intestinal resections	Children <2 yr, known hypersensitivity to drug, acute dysentery characterized by blood in stools and fever, acute UC or pseudomembranous colitis associated with broad-spectrum ABx	Abdominal pain or discomfort, drowsiness or dizziness, tiredness, dry mouth, N/V, hypersensitivity reaction
	diphenoxylate/ atropine	Lomotil®	5 mg PO TID to QID	Inhibits GI propulsion via direct action on smooth muscle, resulting in a decrease in peristaltic action and increase in transit time	Adjunctive therapy for diarrhea, as above	Hypersensitivity to diphenoxylate or atropine, jaundice, pseudomembranous enterocolitis, diarrhea caused by enterotoxin producing bacteria	Dizziness, drowsiness, insomnia, headache, N/V, cramps, allergic reaction
	eluxadoline	Viberzil®	75-100 mg BID	Bowel opioid modulator	IBS Diarrhea	Pancreatic disease, excess EtOH, gallstones or other biliary disease	Pancreaticobiliary pain including sphincter of Oddi dysfunction
Antiemetics	dimenhydrinate	Gravol®	25-50 mg PO/IV/IM q4-6 h PRN	Competitive H_1 receptor antagonist in GI tract, blood vessels, and respiratory tract. Blocks chemoreceptor trigger zone. Diminishes vestibular simulation and disrupts labyrinthine function through central anticholinergic action	Motion sickness, radiation sickness, postoperative vomiting, and drug-induced N/V	Hypersensitivity to drug	Xerostomia, sedation
	prochlorperazine	Stemetil®	5-10 mg PO/IV/IM BID-TID PRN	D_1, D_2receptor antagonist in chemoreceptor trigger zone and α-adrenergic and anticholinergic effects Depresses reticular activating system (RAS) affecting emesis	Postoperative N/V, antipsychotic, anxiety	Hypersensitivity to drug	Dystonia, extrapyramidal symptoms (EPS), seizure, NMS (rarely)
	metoclopramide	Maxeran®	10 mg IV/IM q2-3 h pm, 10-15 mg PO QID (30 min before meals and qhs)	Dopamine and 5-HT receptor antagonist in chemoreceptor trigger zone. Enhances response to ACh in upper GI tract, enhancing motility and gastric emptying. Increases LES tone	GERD, diabetic gastroparesis, postoperative and chemotherapy induced N/V, migraines, constipation	Hypersensitivity to drug, GI obstruction, perforation, hemorrhage, pheochromocytoma, seizures, and EPS	Restlessness, drowsiness, dizziness, fatigue, EPS, some rare serious side effects include NMS, agranulocytosis

Table 27. Common Drugs Prescribed in Gastroenterology

Class	Generic Drug Name	Trade Name	Dosing	Mechanism of Action	Indications	Contraindications	Side Effects
	ondansetron	Zofran®	Depends on procedure, generally 8-16 mg PO	Selective 5-HT_3 receptor antagonist in central chemoreceptor trigger zone and peripherally on vagus nerve	N/V caused by cancer chemotherapy and radiation therapy; multiple off label uses, including gastroenteritis N/V	Morphine, hypersensitivity to drug	Constipation, diarrhea, increased liver enzymes, headache, fatigue, malaise, cardiac dysrhythmia
	granisetron	Kytril®	1 mg PO BID (for nausea from chemotherapy/ radiation)	Same as above	N/V caused by cancer chemotherapy and radiation therapy	Same as above	Constipation, prolonged QT interval (rarely)
Prokinetic Agents	domperidone	Motilium®	GI motility disorder (e.g. gastroparesis): 10 mg TID	peripherally acting D_2 receptor blocker, main effect in the upper GI tract (i.e. increased esophageal peristalsis, gastric motility), antiemetic properties	upper GI motility disorders (e.g. gastroparesis, subacute gastritis), prevention of nausea associated with dopamine-agonists	hypersensitivity to domperidone, prolonged QT interval, prolactinoma, electrolyte disturbances, CYP3A4 inhibitors, mechanical GI obstruction or perforation, GI hemorrhage, severe hepatic dysfunction, children <2 yr	cardiac arrhythmia (use lowest dose for shortest duration) and hyperprolactinemia causing hypogonadism, breast engorgement, and galactorrhea
	prucalopride	Resotran® Motegrity®	2 mg PO QD	high affinity 5-HT_4 agonist, main effect in the lower GI tract (i.e. increased colonic peristalsis, ameliorates gastroparesis)	chronic idiopathic constipation	hypersensitivity to prucalopride, GI obstruction or perforation, severe inflammation co-morbidity (e.g. Crohn's disease, UC, toxic megacolon)	headache, fatigue, dizziness, abdominal pain, N/V, diarrhea, abdominal distention
Aminosalicylates (5-ASAs)	mesalamine	Pentasa® Salofalk® Asacol® Mesasal®	CD: 1 g PO TID/QID Active UC: 1 g PO QID Maintenance UC: 1.6 g PO divided doses daily also as suppositories and enemas	5-ASA: Blocks arachidonic acid metabolism to prostaglandins and leukotrienes	Mild to moderate UC	Hypersensitivity to mesalamine salicylates; Asacol® contains phthalate, potential urogenital teratogenicity for male fetus	Abdominal pain, constipation, arthralgia, headache
	sulfasalazine	Salazopyrin®	3-4 g/d PO in divided doses	Compound composed of 5-ASA bound to sulfapyridine, hydrolysis by intestinal bacteria releases 5-ASA, the active component	Mild to moderate UC	Hypersensitivity to sulfasalazine, sulfa drugs, salicylates; intestinal or urinary obstruction, porphyria	Rash, loss of appetite, N/V, headache, oligospermia (reversible)
Immuno-suppressive Agents	6-mercaptopurine (6-MP)	Purinethol®	CD: 1.5 mg/kg/d PO	Immunosuppressive	IBD: active inflammation and to maintain remission	Hypersensitivity to mercaptopurine, prior resistance to mercaptopurine or thioguanine, history of treatment with alkylating agents, hypersensitivity to azathioprine, pregnancy	Pancreatitis, bone marrow suppression, increased risk of cancer
	azathioprine	Azasan® Imuran®	IBD: 2-3 mg/kg/d PO	Same as above	Same as above	Same as above	Same as above
	prednisone		Induction of remission for acute exacerbations: 20-40 mg PO once daily; taper 2.5-5 mg/wk until discontinued	Anti-inflammatory	Symptomatic moderate to severe CD and UC	Hypersensitivity to prednisone, systemic fungal infections	Hyperglycemia, insomnia, osteoporosis, weight gain, increased risk of infections
Biologics	infliximab	Remicade®	5-10 mg/kg IV over 2 h	Monoclonal antibody to TNFα	Medically refractory CD	Heart failure, moderate to severe, doses >5 mg/kg	Reported cases of reactivated TB, PCP, lymphoma, other infections Other TNFα share similar serious side effects
	adalimumab	Humira®	CD induction: four 40 mg SC on day 1, then 80 mg 2 wk later (day 15) CD maintenance: 40 mg every other wk beginning day 29	Monoclonal antibody to TNFα	Medically refractory CD or poor response to infliximab	Hypersensitivity to adalimumab Severe infection Moderate-to-severe heart failure	Headaches, skin rashes, upper respiratory tract infection
	golimumab	Simponi®	RA: 2 mg/kg at wk 0, 4, and then every 8 wk thereafter (use with methotrexate) UC induction: 200 mg SC at wk 0, then 100 mg at wk 2 UC maintenance: 50 mg every 4 wk	Monoclonal antibody to TNFα	Active ankylosing spondylitis Psoriatic arthritis Moderate-to-severe active RA (combined with methotrexate) UC: medically refractory UC	Hypersensitivity to golimumab or latex Severe infection Moderate-to-severe heart failure	
	vedolizumab	Entyvio®	CD/UC: 300 mg at 0, 2, 6 wk and then every 8 wk thereafter	Monoclonal antibody to α4β7 integrin	Medically refractory CD/UC, including other TNFα inhibitors and corticosteroids	Hypersensitivity to vedolizumab	Infections, liver injury, and progressive multifocal leukoencephalopathy
	ustekinumab	Stelara®	Induction: single IV weight-based dose on day 1 Maintenance: 90 mg subcutaneous injection every 8 wk	Monoclonal antibody to IgG1K, inhibits signals by IL-12 and IL-23	Moderate to severe CD and UC	Hypersensitivity to ustekinumab	Infections, headaches, joint pain, fever, N/V

Table 27. Common Drugs Prescribed in Gastroenterology

Class	Generic Drug Name	Trade Name	Dosing	Mechanism of Action	Indications	Contraindications	Side Effects
Small Molecules	tofacitinib	Xeljanz®	5-10 mg BID	JAK inhibitor	UC	TB, hepatitis B	Infections, macro-cardiac events, thrombosis (e.g. PE, DVT)
Antibiotics	rifaximin	Zaxine®	550 mg BID or TID	Non-absorbable antibiotic, affects dysbiosis of microbiome	Hepatic encephalopathy Non-constipation IBS Traveller's diarrhea	Nil	Nil

Landmark Gastroenterology Trials

Trial Name	Reference	Clinical Trial Details
PEPTIC ULCER DISEASE		
FAMOUS	Lancet 2009;374:119-25	**Title:** Famotidine for the Prevention of Peptic Ulcers and Oesophagitis in Patients Taking Low-dose Aspirin (FAMOUS): A Phase III, Randomised, Double-blind, Placebo-controlled Trial **Purpose:** Evaluate the efficacy of famotidine in the prevention of peptic ulcers and erosive esophagitis, in patients receiving low-dose aspirin. **Methods:** Patients without erosions or ulcers on upper endoscopy, currently on low-dose aspirin, were randomized to famotidine 20 mg BID or placebo. The primary endpoint was development of new stomach ulcers. **Results:** At 12 wk, gastric ulcers occurred in 3.4% of famotidine patients and 15% of placebo-matched patients (OR 0.20; 95% CI 0.09 to 0.47; P=0.0002). Duodenal ulcers developed in 0.5% of famotidine patients and 8.5% of placebo patients (OR 0.05; 95% CI 0.01 to 0.40; P=0.0045). **Conclusions:** Famotidine is effective in the prevention of gastric and duodenal ulcers, and erosive esophagitis in patients taking low-dose aspirin.
INFLAMMATORY BOWEL DISEASE		
SONIC	NEJM 2010;362:1383-95	**Title:** Infliximab, Azathioprine, or Combination Therapy for Crohn's Disease **Purpose:** Compare the efficacy and safety of infliximab and azathioprine therapy alone or in combination, in patients with CD. **Methods:** CD patients who had not undergone previous biologic or immunosuppressive therapy were randomized to infliximab 5 mg/kg IV infusion or 2.5 mg oral azathioprine, or combination therapy of both drugs. **Results:** Among patients receiving combination therapy, 56.8% were in steroid-free remission, compared with 44.4% of patients receiving infliximab monotherapy, and 30% receiving azathioprine monotherapy (P<0.001 for comparison with combination; P=0.06 for comparison with infliximab). **Conclusions:** Patients' CD treated with infliximab monotherapy or infliximab-azathioprine combination had better corticosteroid-free remission than azathioprine monotherapy recipients.
A Comparison of Methotrexate with Placebo for the Maintenance of Remission in Crohn's Disease	NEJM 2000;342:1627-32	**Title:** A Comparison of Methotrexate with Placebo for the Maintenance of Remission in Crohn's Disease **Purpose:** Evaluate the role of methotrexate in maintaining remission of CD. **Methods:** Patients with chronically active CD who entered remission were randomized to methotrexate 15 mg IM or placebo for 15 wk. The primary endpoint was rates of remission at wk 40. **Results:** At the follow-up period of 40 wk, 65% of methotrexate patients were in remission compared to 39% of patients in the placebo group (risk reduction 26.1%; 95% CI 4% to 47.8%; P=0.04). None of the methotrexate patients reported serious adverse events. **Conclusions:** Patients with CD in remission saw increased remission rates and fewer relapse treatments at 40 wk.
Adalimumab Induction Therapy for Crohn's Disease Previously Treated with Infliximab	Ann Intern Med 2007;146:829-38	**Title:** Adalimumab Induction Therapy for Crohn's Disease Previously Treated with Infliximab **Purpose:** Determine the efficacy of adalimumab in symptomatic CD patients despite infliximab treatment. **Methods:** 325 adults with moderate-severe active CD were randomized to induction doses of adalimumab 160 mg and 80 mg at 0 and 2 wk respectively, or time-matched placebo. The primary endpoint was induction of remission at 4 wk. **Results:** Remission was achieved at 4 wk in 21% of adalimumab patients compared with 7% of placebo patients (95% CI 6.7% to 21.6%). **Conclusions:** Adalimumab induces remission more frequently than placebo in adult patients with symptomatic CD despite infliximab therapy.
UNIFI	NEJM 2019;381:1201-14	**Title:** Ustekinumab as Induction and Maintenance Therapy for Ulcerative Colitis **Purpose:** Determine the effectiveness of ustekinumab as induction and maintenance therapy in patients with UC. **Methods:** 961 patients with moderate-severe UC were randomized to IV induction ustekinumab (130 mg), or placebo. The primary endpoint was clinical remission determined by the Mayo scale. **Results:** The primary endpoint occurred in 15.6% of patients in the intervention group compared with 5.3% of placebo patients (P<0.001). The incidence of serious adverse events was similar between groups. **Conclusions:** Ustekinumab was more effective than placebo for inducing and maintaining remission in patients with moderate-to-severe UC.
VARSITY	NEJM 2019;381:1215-26	**Title:** Vedolizumab versus Adalimumab for Moderate-to-Severe Ulcerative Colitis **Purpose:** Compare efficacy of vedolizumab versus adalimumab in patients with moderate-severe UC. **Methods:** Adults with moderate-severe active UC were randomized to IV infusions of vedolizumab 300 mg or subcutaneous adalimumab 40 mg (total weekly dose 160 mg). The primary outcome was clinical remission at wk 52 as determined by the Mayo scale. **Results:** At wk 52, clinical remission was observed in 31.3% of vedolizumab patients compared to 22.5% of adalimumab patients (95% CI 2.5 to 15.0; P=0.006). Steroid-free remission occurred in 12.6% of vedolizumab patients and 21.8% of adalimumab patients (95% CI 18.9 to 0.4). **Conclusions:** In patients with moderate-to-severe UC, vedolizumab was superior to adalimumab with respect to achievement of clinical remission and endoscopic improvement, but not corticosteroid-free clinical remission.

Trial Name	Reference	Clinical Trial Details
LIVER DISEASE		
MELD Score as A Predictor Of Death in Chronic Liver Disease	Gastroenterology 2003;124:91-96	**Title:** MELD Score as A Predictor Of Death in Chronic Liver Disease **Purpose:** Assess the capability for the MELD score to correctly rank potential liver transplant recipients. **Methods:** The MELD score was prospectively applied to estimate 3-mo mortality in 3437 adult liver transplant candidates with chronic liver disease. **Results:** Waiting list mortality increased directly in proportion to the MELD score. Using 3-mo mortality as the endpoint, the ROC curve for MELD was 0.83 compared to 0.76 for the Child-Turcotte-Pugh score. **Conclusions:** MELD score can be applied for allocation of donor livers as it accurately predicts 3-mo mortality in patients with chronic liver failure.
PROVE 3	NEJM 2010;362:1292-1303	**Title:** Telaprevir for Previously Treated Chronic HCV Infection **Purpose:** Study the efficacy of telaprevir in patients without a sustained virologic response to peginterferon therapy. **Methods:** Patients with HCV genotype 1 without sustained virologic response to peginterferon therapy were randomized to one of four telaprevir and peginterferon treatment groups. The primary endpoint was sustained virologic response 24 wk after the last dose. **Results:** The rates of sustained virologic response in the three telaprevir groups were significantly higher than the control group rates (14%, P<0.001, P<0.001, P=0.02). Discontinuation of the drugs due to adverse events was more frequent in the telaprevir groups than in the control group (15% vs. 4%). **Conclusions:** In HCV-infected patients in whom initial peginterferon therapy failed, retreatment with telaprevir in combination with peginterferon and ribavirin was more effective than the latter two alone.
SPRINT-2	NEJM 2011;364:1195-1206	**Title:** Boceprevir for Untreated Chronic HCV Genotype 1 Infection **Purpose:** Evaluate virologic response with additional boceprevir treatment in patients with HCV genotype 1 infection. **Methods:** Previously untreated adults with HCV genotype 1 infection were randomized to placebo plus peginterferon-ribavirin or boceprevir plus peginterferon-ribavirin. The primary endpoint was sustained virologic response. **Results:** A virologic response was achieved in 40% of group 1, 67% in group 2 and 68% in group 3. **Conclusions:** The addition of boceprevir to standard therapy of peginterferon-ribavirin, compared with standard therapy alone, increased rates of sustained virologic response in chronically HCV infected adults.
Rifaximin Treatment in Hepatic Encephalopathy	NEJM 2010;362:1071-81	**Title:** Rifaximin Treatment in Hepatic Encephalopathy **Purpose:** Evaluate the efficacy of rifaximin in the prevention of hepatic encephalopathy secondary to cirrhosis. **Methods:** 299 patients in remission from recurrent hepatic encephalopathy were randomized to rifaximin 550 mg BID or placebo for 6 mo. The primary endpoint was time for the first breakthrough episode. **Results:** Rifaximin reduced the risk of a hepatic encephalopathy episode (hazard ratio 0.42; 95% CI 0.28 to 0.64; P<0.001). A breakthrough episode occurred in 22.1% of rifaximin-treated patients compared to 45.9% of placebo patients (hazard ratio 0.5; 95% CI 0.29 to 0.87; P=0.01). The incidence of adverse events was similar between groups. **Conclusions:** The antibiotic rifaximin was successful in maintaining remission from hepatic encephalopathy and reducing hospitalizations.
Prednisolone or Pentoxifylline For Alcoholic Hepatitis	NEJM 2015;372:1619-28	**Title:** Prednisolone or Pentoxifylline For Alcoholic Hepatitis **Purpose:** To elucidate the benefits of pentoxifylline and prednisolone for the treatments of severe alcoholic hepatitis. **Methods:** Patients with severe alcoholic hepatitis were randomized to one of four groups: double-matched placebo, prednisolone plus matched placebo, pentoxifylline plus matched placebo, or prednisolone plus pentoxifylline. The primary endpoint was mortality at 28 d. **Results:** Mortality at 28 d was 17% in the first group, 14% in the second group, 19% in the third group, and 13% in the fourth group. At 90 d and 1 yr, there were no significant differences between groups. **Conclusions:** For alcoholic hepatitis, prednisolone improved survival at a level below statistical significance. Pentoxifylline did not improve survival.

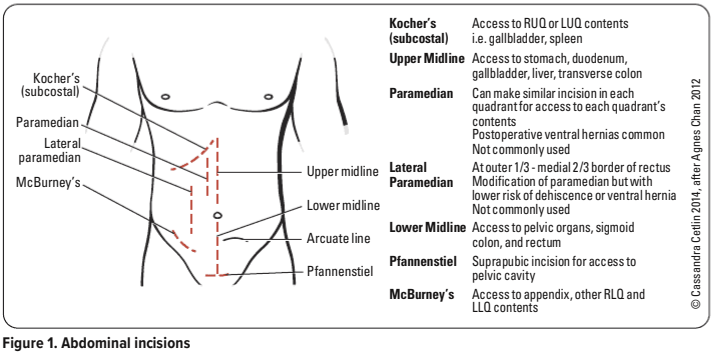
Acronyms

5-FU	5-fluorouracil
AAA	abdominal aortic aneurysm
ABG	arterial blood gas
ABI	ankle brachial index
ALND	axillary lymph node dissection
APR	abdominoperineal resection
ARDS	acute respiratory distress syndrome
ATN	acute tubular necrosis
AXR	abdominal x-ray
BRBPR	bright red blood per rectum
BCS	breast conserving surgery
CBD	common bile duct
CEA	carcinoembryonic antigen
CF	cystic fibrosis
CHD	common hepatic duct
CRC	colorectal cancer
CVA	costovertebral angle
CVP	central venous pressure
DCIS	ductal carcinoma in situ
DHEAS	dehydroepiandrosterone sulfate
DIC	disseminated intravascular coagulation
DPL	diagnostic peritoneal lavage
DRE	digital rectal exam
EBL	estimated blood loss
ERCP	endoscopic retrograde cholangiopancreatography
EUA	examination under anesthesia
EUS	endoscopic ultrasound
FAP	familial adenomatous polyposis
FAST	focused abdominal sonography for trauma
FNA	fine needle aspiration
FNH	focal nodular hyperplasia
FOBT	fecal occult blood test
GERD	gastroesophageal reflux disease
GIST	gastrointestinal stromal tumour
GU	genitourinary
HCC	hepatocellular carcinoma
HDGC	hereditary diffuse gastric carcinoma
HIDA	hepatobiliary imino-diacetic acid
HNPCC	hereditary nonpolyposis colorectal cancer
I&D	incision and drainage
IBD	inflammatory bowel disease
IPAH	idiopathic pulmonary arterial hypertension
IPF	idiopathic pulmonary fibrosis
IUGR	intrauterine growth restriction
IVC	inferior vena cava
IVIG	intravenous immune globulin
LAR	low anterior resection
LBO	large bowel obstruction
LCIS	lobular carcinoma in situ
LES	lower esophageal sphincter
LGIB	lower gastrointestinal bleed
LLQ	left lower quadrant
LMWH	low molecular weight heparin
LUQ	left upper quadrant
LVRS	lung volume reduction surgery
MALT	mucosa-associated lymphoid tissue
MBP	mechanical bowel preparation
MEN	multiple endocrine neoplasia
MIBG	metaiodobenzylguanidine
MIS	minimally invasive surgery
MRCP	magnetic resonance cholangiopancreatography
MSAFP	maternal serum α-fetoprotein
NET	neuroendocrine tumour
NS	normal saline
OCP	oral contraceptive pill
OGD	oesophagogastroduodenoscopy
PMN	polymorphonuclear neutrophils
POD	postoperative day
PPI	proton pump inhibitor
PTC	percutaneous transhepatic cholangiography
PTT	partial thromboplastin time
PUD	peptic ulcer disease
RAI	radioactive iodine
RL	Ringer's lactate
RLQ	right lower quadrant
RUQ	right upper quadrant
SBO	small bowel obstruction
SBFT	small bowel follow-through
SCC	squamous cell carcinoma
SIADH	syndrome of inappropriate anti-diuretic hormone
SMA	superior mesenteric artery
SMV	superior mesenteric vein
SNLB	sentinel lymph node biopsy
TED	thromboembolic deterrent
TEE	transesophageal echocardiogram
TTE	transthoracic echocardiogram
UC	ulcerative colitis
UGI	upper gastrointestinal series
UGIB	upper gastrointestinal bleed
URTI	upper respiratory tract infection
VATS	video-assisted thoracoscopic surgery
VIP	vasoactive intestinal peptide
VTE	venous thromboembolism

Basic Anatomy Review



Kocher's (subcostal)
Paramedian
Lateral paramedian
McBurney's
Upper midline
Lower midline
Arcuate line
Pfannenstiel
Kocher's (subcostal) Access to RUQ or LUQ contents i.e. gallbladder, spleen
Upper Midline Access to stomach, duodenum, gallbladder, liver, transverse colon
Paramedian Can make similar incision in each quadrant for access to each quadrant's contents
Postoperative ventral hernias common
Not commonly used
Lateral Paramedian At outer 1/3 - medial 2/3 border of rectus
Modification of paramedian but with lower risk of dehiscence or ventral hernia
Not commonly used
Lower Midline Access to pelvic organs, sigmoid colon, and rectum
Pfannenstiel Suprapubic incision for access to pelvic cavity
McBurney's Access to appendix, other RLQ and LLQ contents
© Cassandra Cetlin 2014, after Agnes Chan 2012

Figure 1. Abdominal incisions

Lateral Abdominal Wall Layers and their Continuous Spermatic and Scrotal Structures (superficial to deep)

1. skin (epidermis, dermis, subcutaneous fat)
2. superficial fascia
   - Camper's fascia (fatty) → Dartos muscle/fascia
   - Scarpa's fascia (membranous) → Colles' superficial perineal fascia
3. muscle (see *Figure 2 and Figure 3, GS3*)
   - external oblique → inguinal ligament → external spermatic fascia
   - internal oblique → cremasteric muscle/fascia
   - transversus abdominis → posterior inguinal wall
4. transversalis fascia → internal spermatic fascia
5. preperitoneal fat
6. peritoneum → tunica vaginalis

Midline Abdominal Wall Layers (superficial to deep)

1. skin
2. superficial fascia
3. rectus abdominis muscle: in rectus sheath, divided by linea alba (see *Figure 3, GS3*)
   - above arcuate line (midway between symphysis pubis and umbilicus)
     - anterior rectus sheath = external oblique aponeurosis and anterior leaf of internal oblique aponeurosis
     - posterior rectus sheath = posterior leaf of internal oblique aponeurosis and transversus abdominis aponeurosis
   - below arcuate line
     - aponeuroses of external oblique, internal oblique, and transversus abdominis all pass in front of rectus abdominis

4. arteries: superior epigastric (branch of internal thoracic), inferior epigastric (branch of external iliac); both arteries anastomose and lie behind the rectus muscle (superficial to posterior rectus sheath above arcuate line)
5. transversalis fascia
6. peritoneum

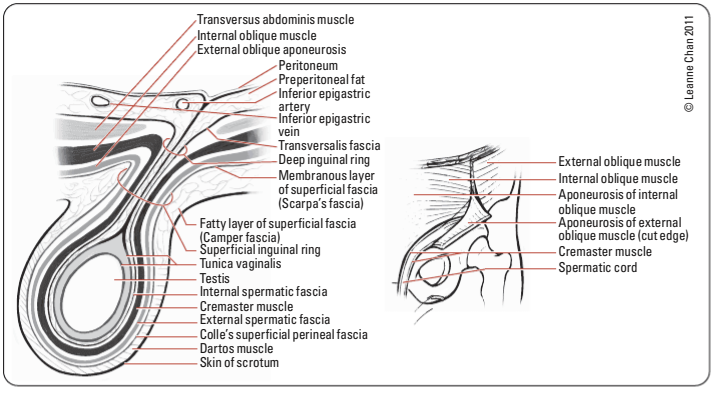


Figure 2. Continuity of the abdominal wall with layers of the scrotum and spermatic cord

Differential Diagnoses of Common Presentations

Acute Abdominal Pain

- acute abdomen = severe abdominal pain of acute onset and requires urgent medical attention
- in patients with acute abdominal pain, the first diagnoses that you should consider are those requiring potential urgent surgical intervention, including:
  - peritonitis
  - bowel obstruction

Table 1. Differential Diagnosis of Acute Abdominal Pain

Right Upper Quadrant (RUQ)	Right Lower Quadrant (RLQ)
Hepatobiliary	**Gastrointestinal**
Biliary colic	Appendicitis*
Cholecystitis*	Crohn's disease
Cholangitis	Tuberculosis of the ileocecal junction
CBD obstruction (e.g. stone, tumour)	Cecal tumour
Hepatitis (includes perihepatitis/Fitz-Hugh-Curtis syndrome)	Intussusception
Gastrointestinal	Mesenteric lymphadenitis (Yersinia)
Pancreatitis	Cecal diverticulitis
Presentation of gastric, duodenal, or pancreatic pathology	Cecal volvulus*
Hepatic flexure pathology (e.g. CRC, subcostal incisional hernia)	Hernia: femoral, inguinal obstruction, Amyand's (and resulting cecal distention)
Genitourinary	**Gynecological**
Nephrolithiasis*	See 'suprapubic'
Pyelonephritis	**Genitourinary**
Renal: mass, ischemia, trauma	See 'suprapubic'
Cardiopulmonary	**Extraperitoneal**
Right lower lobe pneumonia	Abdominal wall hematoma/abscess
Effusion/empyema	Psoas abscess
CHF (causing hepatic congestion and right pleural effusion)	
MI	
Pericarditis	
Pleuritis	
Miscellaneous	
Herpes zoster	
Trauma	
Costochondritis (Infectious*)	

*indicated need for urgent surgical evaluation

In All Patients Presenting with an Acute Abdomen, Order the Following:
Key Tests for Specific Diagnosis
- ALP, ALT, AST, bilirubin
- Lipase/ amylase
- Urinalysis
- β-hCG (in women of childbearing age)
- Troponins
- Lactate

Key Tests for OR Preparation
- CBC, electrolytes, creatinine, glucose
- INR/PTT
- CXR (if history of cardiac or pulmonary disease)
- ECG if clinically indicated by history or if >69 yr and no risk factors

Note: Choosing Wisely does not recommend routine preoperative blood work for ambulatory/elective surgery

Types of Peritonitis

Primary peritonitis: spontaneous without clear etiology

Secondary peritonitis: due to a perforated viscus

Tertiary peritonitis: recurrent secondary peritonitis more often with resistant organisms

Localization of Pain

Most digestive tract pain is perceived in the midline because of bilaterally symmetric innervation; kidney, ureter, ovary, or somatically innervated structures are more likely to cause lateralized pain

Parietal peritoneum: supplied by somatic sensory nerves of body wall. Pain is sharp and well-localized

Visceral peritoneum: supplied by autonomic sensory fibres. Pain is colicky and poorly localized

Table 1. Differential Diagnosis of Acute Abdominal Pain

Left Upper Quadrant (LUQ)	Left Lower Quadrant (LLQ)
Pancreatic Pancreatitis (acute vs. chronic) Pancreatic pseudocyst Pancreatic tumours*	**Gastrointestinal** Diverticulitis* Diverticulosis Colon/sigmoid/rectal cancer Fecal impaction Proctitis (e.g. UC, infectious; i.e. gonococcus or *Chlamydia*) Sigmoid volvulus*
Gastrointestinal Gastritis PUD Splenic flexure pathology (e.g. CRC, ischemia)	Hernia (incarcerated/strangulated*)
Splenic Splenic infarct/abscess* Splenomegaly Splenic rupture* Splenic artery aneurysm	**Gynecological** See 'suprapubic'
Cardiopulmonary (see RUQ and Epigastric)	**Genitourinary** See 'suprapubic'
Genitourinary (see RUQ)	**Extraperitoneal** Abdominal wall hematoma/abscess* Psoas abscess
	See Gynecology, Urology, Respirology, and Cardiology and Cardiac Surgery for further details regarding respective etiologies of acute abdominal pain

EPIGASTRIC	SUPRAPUBIC	DIFFUSE
Cardiac Aortic dissection/ruptured AAA* MI Pericarditis	**Gastrointestinal (see RLQ/LLQ)** Acute appendicitis* IBD	**Gastrointestinal** Peritonitis* Early appendicitis, perforated appendicitis* Mesenteric ischemia* Gastroenteritis/colitis Constipation Bowel obstruction* Pancreatitis IBD Irritable bowel syndrome Ogilvie's syndrome
Gastrointestinal Gastritis GERD/esophagitis PUD Pancreatitis Mallory-Weiss tear	**Gynecological** Ectopic pregnancy* Pelvic inflammatory disease Endometriosis Threatened/incomplete abortion* Hydrosalpinx/salpingitis Ovarian torsion* Hemorrhagic fibroid Tubo-ovarian abscess Gynecological tumours	**Cardiovascular/Hematological** Aortic dissection* Ruptured AAA* Sickle cell crisis
	Genitourinary Cystitis (infectious, hemorrhagic) Hydroureter/urinary colic Epididymitis Testicular torsion* Acute urinary retention	**Genitourinary/Gynecological** Perforated ectopic pregnancy* Pelvic inflammatory disease Acute urinary retention
	Extraperitoneal Rectus sheath hematoma	**Endocrinological** Carcinoid syndrome* Diabetic ketoacidosis Addisonian crisis Hypercalcemia
		Other Lead poisoning Tertiary syphilis

*indicated need for urgent surgical evaluation

Referred Pain

Biliary colic: to right shoulder or scapula

Renal colic: to groin

Appendicitis: periumbilical to RLQ

Pancreatitis: to back

Ruptured AAA: to back or flank

Perforated ulcer: to RLQ (right paracolic gutter)

Hip pain: to groin

Ovarian torsion: to flank or groin

Most Common Presentations of Surgical Pain

Sudden onset with rigid abdomen = perforated viscus

Pain out of proportion to physical findings = ischemic bowel

Vague pain that subsequently localizes = appendicitis or other intra-abdominal process that irritates the parietal peritoneum

Waves of colicky pain = bowel obstruction

Acute Abdominal Pain Mnemonic

ABDOMINAL
Appendicitis
Biliary tract disease
Diverticulitis
Ovarian disease
Malignancy
Intestinal obstruction
Nephritic disorders
Acute pancreatitis
Liquor/ethanol

Abdominal Mass

Table 2. Differential Diagnosis of Abdominal Mass

RUQ	Upper Midline	LUQ
Gallbladder: cholecystitis, cholangiocarcinoma, peri-ampullary malignancy, cholelithiasis **Biliary tract:** Klatskin tumour Liver: hepatomegaly, hepatitis, abscess, tumour (hepatocellular carcinoma, metastatic tumour, etc.)	**Pancreas:** pancreatic adenocarcinoma, other pancreatic neoplasms, pseudocyst **Abdominal aorta:** AAA (pulsatile) **GI:** gastric tumour (adenocarcinoma, gastrointestinal stromal tumour, carcinoid tumour), MALT lymphoma	**Spleen:** splenomegaly, tumour, abscess, subcapsular splenic hemorrhage, can also present as RLQ mass if extreme splenomegaly **Stomach:** tumour
RLQ	**Lower Midline**	**LLQ**
Intestine: stool, tumour (CRC), mesenteric adenitis, appendicitis, appendiceal phlegmon or other abscess, typhlitis, intussusception, Crohn's inflammation **Ovary:** ectopic pregnancy, cyst (physiological vs. pathological), tumour (serous, mucinous, struma ovarii, germ cell, Krukenberg) **Fallopian tube:** ectopic pregnancy, tubo-ovarian abscess, hydrosalpinx, tumour	**Uterus:** pregnancy, leiomyoma (fibroid), uterine cancer, pyometra, hematometra **GU:** bladder distention, tumour	**Intestine:** stool, tumour, abscess (see RLQ) **Ovary:** see RLQ **Fallopian tube:** see RLQ

Pancreatitis can look like a surgical abdomen, but is rarely an indication for immediate surgical intervention

Gastrointestinal Bleeding

- see Gastroenterology, G28 and G30

Indications for Surgery

- failure of medical management (after at least 2 endoscopic attempts at management)
- exsanguinating hemorrhage: hemodynamic instability despite vigorous resuscitation
- recurrent hemorrhage with up to two attempts of endoscopic hemostasis
- prolonged bleeding with transfusion requirement >3 units
- bleeding at rate >1 unit/8h

Indications for Urgent Operation

IHOP
Ischemia
Hemorrhage
Obstruction
Perforation

Surgical Management of GI Bleeding

- UGIB
  - bleeding from a source proximal to the ligament of Treitz
  - often presents with hematemesis and melena unless very brisk (then can present with hematochezia), may present with anemia, hypovolemic shock
  - initial management with PPIs and endoscopy; if fails, then consider surgical management appropriate to etiology
  - PUD accounts for approximately 55% of severe UGIB
- LGIB
  - bleeding from a source distal to the ligament of Treitz
  - often presents with BRBPR unless proximal to transverse colon, rarely melena (right-sided colonic bleeding)
  - initial management with colonoscopy to detect and potentially stop source of bleeding
  - 75% of patients will spontaneously stop bleeding, however if bleeding continues, barium enema should NOT be performed
  - angiography or RBC scan to determine source as indicated
  - surgery indicated if bleeding is persistent - aimed at resection of area containing source of bleeding
  - for obscure bleed conduct wireless capsule endoscopy, may require blind total colectomy if the source is not found
  - diverticular bleeding is the most common cause of LGIB (accounting for 40% of cases)

Overt Bleeding: obvious hematemesis, hematochezia or melena per rectum (i.e. visible to naked eye)
Occult Bleeding: bleeding per rectum is not obvious to naked eye (e.g. positive guaiac FOBT)
Obscure Bleeding: bleeding with no identifiable source after colonoscopy and endoscopy (source usually in small bowel). Can be either overt or occult

Table 3. Differential Diagnosis of GI Bleeding

Anatomical Source	Etiology	
Hematological	Excess anticoagulation (warfarin, heparin, etc.) Excess antiplatelet (clopidogrel, ASA)	DIC Congenital bleeding disorders
Nose	Epistaxis	
Esophagus	Esophageal varices Mallory-Weiss tear Esophagitis	Aorto-esophageal fistula (generally post endovascular aortic repair)* Esophageal cancer
Stomach	Gastritis Gastric varices Dieulafoy's lesion	Gastric ulcer Gastric cancer*
Duodenum	Duodenal ulcer Perforated duodenal ulcer*	Duodenal cancer*
Jejunum	Tumours* Polyps Ulcers	
Ileum and Ileocecal Junction	Meckel's diverticulum Small bowel obstruction	Crohn's disease* Tuberculosis of ileocecal junction
Large Intestine	Colorectal cancer* Mesenteric thrombosis/ischemic bowel* UC* (subtotal colectomy if failure of medical management) Angiodysplasia Diverticulosis (*if bleeding is persistent)	Crohn's disease (less frequently presents with bleeding)* Pancolitis (infectious, chemotherapy, or radiation induced) Bleeding post-gastrointestinal anastomosis
Sigmoid	Diverticulosis (*if bleeding is persistent) Sigmoid cancer* Bleeding post-polypectomy	Polyps (*if not amenable to colonoscopic polypectomy) IBD
Rectum and Anus	Hemorrhoids Fissures Rectal cancer* Anal varices	Polyps (*if not amenable to colonoscopic polypectomy) Crohn's or UC* Solitary rectal ulcer syndrome

*Managed surgically in most cases

Bloodwork for GI Bleeds
CBC (including platelet count), serum chemistries (electrolytes, BUN, LFTs, etc.), coagulation studies (INR, PT, PTT), blood type and crossmatch if anticipate transfusion

Jaundice

- see Gastroenterology, G45

Biochemical Signs for Differentiating Jaundice
Hepatocellular: Elevated bilirubin + elevated ALT/AST
Cholestatic: Elevated bilirubin + elevated ALP/GGT ± duct dilatation upon biliary U/S
Hemolysis: ↓ haptoglobin ↑ LDH

Note: cholestatic jaundice is often surgical

Preoperative Preparations

Considerations

- informed consent (see Ethical, Legal, and Organizational Medicine, ELOM12)
- screening questionnaire to determine risk factors e.g. age, exercise capacity, medication use, allergies, exposure to people with infection (i.e. COVID-19)
- consider preoperative anesthesia, medicine consult as indicated to optimize patient status
- NPO according to fasting guidelines (see Anesthesia, A5)
- IV-balanced crystalloid at maintenance rate (4:2:1 rule for paediatrics, roughly 100-125 cc/h for adults): NS or RL (RL most common); bolus to catch up on estimated losses including losses from bowel prep
  - appropriate use of fluids perioperatively decreases risk of cardiorespiratory complications
- patients can take their regular medications except for hypoglycemic agents, diuretics, and ACEis
- patients with primary adrenal insufficiency (e.g. Addison's disease) or secondary adrenal insufficiency (e.g. glucocorticoid use) may require additional glucocorticoid stress dose coverage
- anticoagulation/antiplatelet medication must be managed to decrease surgical bleeding but not put patient at risk for increased thrombotic events (e.g. Bridging: switching from warfarin to LMWH, easier to start/stop as needed)
- prophylactic antibiotics depending on wound class (immediately/within 1 h prior to incision): cefazolin (skin flora coverage) ± metronidazole (GI flora coverage) for contaminated cases
- role of MBP: Current evidence suggests that use of MBP preoperatively has no impact on postoperative complications, and therefore, routine use of MBP for non-LAR elective colorectal surgery is not recommended
  - MBP is indicated in open or laparoscopic anterior resection i.e. rectal resection where anastomosis is at or below sacral promontory; given with antibiotics
- assess risk for postoperative VTE prior to surgery based on procedure- and patient-related factors; tools such as Caprini Score can be used
  - only hold VTE prophylaxis if epidural is expected
- smoking cessation and weight loss preoperatively can significantly decrease postoperative complications
- infection: delay elective surgery until infection managed, including respiratory infection (particularly in asthma patients)
- when scheduling elective surgeries following a COVID-19 diagnosis, consider the severity of COVID-19 illness, the risks of complications, and risks of delaying surgery

Table 4. Recommendations for Timing of Surgery following Recovery from COVID-19 with Consideration of Individual Risk/Benefits

Priority of Surgical Procedure	Clinical Severity of COVID-19 Infection			
	Mild	Moderate	Severe	Critically ill
	Mild (suspected or confirmed) COVID-19 and/or asymptomatic and/or upper respiratory tract infection	Moderate symptomatic COVID-19 not requiring hospitalization and/or persistent symptoms	Lung involvement requiring hospitalization and/or significant comorbidities and/or immunocompromised	Severe COVID-19 with ICU admission and/or meet criteria for severe disease and/or severely immunocompromised
Urgent or Emergent <2 wk ACATS and PCATS Urgent within 3, 7 or 14 d	Do case urgently/ emergently	Do case urgently/ emergently	<7 wk post-infection consider non-operative options if safe and available	<7 wk post-infection consider non-operative options if safe and available
Urgent (28 or 42 d) 2-6 wk ACATS/PCATS	4 -7 wk post infection	7 wk post infection	7 wk post infection	12 wk post infection
Elective (>43 d) >6 wk ACATS/PCATS				

Investigations

- see Anesthesia, A4
- routine preoperative laboratory investigations for elective procedures should be selective
  - only ASA class and surgical risk have been found to independently predict postoperative adverse effects
- blood components: group and screen or cross and type depending on procedure
- CBC, electrolytes, creatinine
- INR/PT, PTT
- CXR (PA and lateral) for patients with history of cardiac or pulmonary disease
- ECG as indicated by history or age>69 and no risk factors
- β-hCG testing in all women of reproductive age
- for patients undergoing low-risk surgery without systemic disease (ASA I or II), routine preoperative chest x-rays, CBC, INR, and PTT should be avoided

Bilirubin Levels

	Pre-hepatic	Intra-hepatic	Post-hepatic
Serum Bilirubin			
Indirect	↑	↑	N
Direct	N	↑	↑
Urine			
Urobilinogen	↑	↑	–
Bilirubin	–	+	+
Fecal			
Urobilinogen	↑	↑	–

In patients with liver disease and an acute abdomen, spontaneous bacterial peritonitis must be ruled out

Surgical Emergencies: Take an AMPLE History

Allergies
Medications
Past medical/surgical history (including anesthesia and bleeding disorders)
Last meal
Events – HPI

Best Practice in General Surgery (BPIGS)
http://www.bpigs.ca/
Best Practice in Surgery is a resource from the quality improvement program at the University of Toronto Department of Surgery. Since its inception, it has expanded beyond general surgery best practices and provides EBM guidelines for a variety of fields and procedures

Mechanical Bowel Preparation Strategies: A Clinical Practice Guideline developed by the University of Toronto's Best Practice in Surgery
Informed by: Can J Surg 2010;53:385-395
14 RCTs (5071 participants), 8 meta-analyses
1. All open/laparoscopic colorectal procedures (excluding LARs ± diverting stoma)
   - No MBP
   - No dietary restrictions before NPO
   - Fleet enema for left colon anastomoses with transrectal stapling
2. Open/laparoscopic LAR ± diverting stoma
   - MBP
   - No dietary restrictions before MBP; clear fluids after MBP complete

Drains

- NG tube
  - indications: gastric decompression, analysis of gastric contents, irrigation/dilution of gastric contents, feeding, and/or administration of medications, if necessary
  - 2 types: NG tube (for drainage or feeding) and Dobhoff (for feeding only)
  - insertion should be done in stages with x-ray protocol to avoid injury
  - contraindications: suspected basal skull fracture, obstruction of nasal passages, esophageal stricture, esophageal varices
- Foley catheter with urometer
  - indications: to accurately monitor urine output, decompression of bladder, relieve obstruction, rapidly expanding suprapubic mass
  - contraindications: suspected urethral injury and difficult insertion of catheter

Drain Size
Measured by the unit French:
French = diameter (mm) x 3

Surgical Complications

- general principles in preventing complications during the postoperative period include:
  - frequent examination of the patient (daily or more) and their wound
  - removal of surgical tubes as soon as possible (e.g. Foley catheters and surgical drains)
  - early mobilization
  - monitor fluid balance and electrolytes
  - analgesia - enough to adequately address pain (minimize opioids through routine use of anti-inflammatories and acetaminophen)

Postoperative Fever

- postoperative fever is considered a temperature higher than 38°C on two consecutive postoperative days or higher than 39°C on any postoperative day
- fever does not necessarily imply infection, particularly in the first 24-48 h postoperatively
- fever may not be present or may be blunted if patient is receiving chemotherapy, glucocorticoids, or other immunosuppressive agents
- timing of fever may help identify cause
- hours after surgery - POD #1
    - inflammatory reaction in response to physiological stress from surgery; most common cause of fever on POD #1-3 and unlikely to be infectious (unless necrotizing fasciitis or another severe infection)
    - reaction to blood products received during surgery
    - malignant hyperthermia
  - POD #1-2 (acute)
    - atelectasis
    - early necrotizing fasciitis wound infection (especially *Clostridium perfringens*, β-hemolytic Group A *Streptococcus*); feel for crepitus and look for "dishwater" drainage
    - aspiration pneumonitis
    - other: acute adrenal insufficiency, thyroid storm, and transfusion reaction
  - POD #3-7: likely infectious
    - UTI, surgical site infection, IV site/line infection (commonly with *Staphylococcus*), septic thrombophlebitis, and leakage at bowel anastomosis (tachycardia, hypotension, oliguria, and abdominal pain)
  - POD #8+
    - intra-abdominal abscess, DVT/PE (can be anytime postoperative, most commonly POD #8-10, may occur earlier but recognition is often delayed), and drug fever
    - other: URTI, infected seroma/biloma/hematoma, *C. difficile* colitis, and endocarditis

Treatment

- resuscitation then treat primary cause

Wound/Incisional Complications

WOUND CARE (see Plastic Surgery, PL8)

- can shower POD #2-3 after epithelialization of wound (or earlier depending on dressing)
- most dressings can be removed POD #2 and left uncovered if dry
- Steri strips or dermabond glue should be left on for up to 2 wk
- examine wound for wet dressing, signs of infection (fever, tachycardia, and pain)
- skin sutures and staples can be removed POD #7-10
  - exceptions: incision crosses crease (groin), closed under tension, in extremities (hand) or patient factors (elderly, corticosteroid use, or immunosuppressed) removed POD #14 or earlier if there are signs of infection
- negative pressure dressings consist of foam and suction, promote granulation
  - ideal for large (grafted sites) or non-healing wounds (irradiated skin or ulcer)

DRAINS

- drains may be placed selectively at the time of surgery to prevent fluid accumulation (blood, pus, serum, bile, and urine)
  - can be used to assess quantity of third space fluid accumulation postoperatively
- potential route of infection; to decrease risk of wound infection bring out through separate incision (vs. operative wound) and remove as soon as possible
- types of drains
  - open (e.g. Penrose), higher risk of infection
  - closed: 1) gravity drainage (e.g. Foley catheter); 2) underwater-seal drainage system (e.g. chest tube); 3) suction drainage (e.g. Jackson-Pratt)
  - sump (e.g. NG tube)
- monitor drain outputs daily
- drains should be removed once drainage is minimal (usually <30-50 cc/24 h)
- drains do not guarantee that the patient will not form a collection of fluid
- ridged drains can erode through internal structures, and excessive suction can cause necrosis
- evidence does not support routine postoperative drainage of abdominal cavity

SURGICAL SITE INFECTION

Etiology

- most surgical wounds are contaminated by bacteria often consisting of normal endogenous flora from skin, respiratory, GU, or GI tracts (depending on surgery)
  - e.g. skin flora (Gram positive cocci: *S. aureus, Streptococcus* spp.) and GI flora (Gram-positive microbes: *Enterococcus* spp., Clostridium spp.; Gram-negative rods: *E. coli*; anaerobic species)

Risk Factors

Table 5. Classification of Surgical Wound Contamination

Classification	Clean	Clean-Contaminated	Contaminated	Dirty/Infected
Definition	Incision under sterile conditions; nontraumatic; no entrance of hollow organ	Incision under sterile conditions; ENTRANCE of hollow viscus with no spillage; no evidence of active infection; minimal contamination with no spillage	Incision under sterile conditions; MAJOR contamination of wound during procedure (i.e. gross spillage of stool, infection in biliary, respiratory, or GU systems)	Established infection present before wound is made in skin; traumatic wound with delayed treatment Traumatic wound with delayed treatment
Example	Hernia repair	Routine cholecystectomy; colon resection	Bowel obstruction with enterotomy and spillage of contents; necrotic bowel resection; fresh traumatic wounds	Appendiceal abscess; traumatic wound with contaminated devitalized tissue; perforated viscus
Infection Rate	<2%	3-4%	7-10%	30-40%
Wound Closure	Primary closure	Primary closure	Often secondary closure	Secondary closure

- patient characteristics
  - age, DM, steroids, immunosuppression, smoking, obesity, burn, malnutrition, patient with other infections, traumatic wound, radiation, and chemotherapy
- other factors
  - prolonged preoperative hospitalization, skin preparation, multiple antibiotics, reduced blood flow, break in sterile technique, foreign bodies (drains, sutures, grafts), excessive tension, hematoma, seroma, hypoxemia, and hypothermia

Prophylaxis

- preoperative antibiotics for most surgeries (cefazolin ± metronidazole or if β-lactam allergy, clindamycin ± gentamicin or vancomycin)
  - within 1 h pre-incision; can re-dose at 1-2 half-lives (~q4-8 h) in the OR
  - not required for low-risk or clean surgery, e.g. elective thyroidectomy, cholecystectomy, hemorrhoidectomy, fistulotomy, and sphincterotomy for fissure
  - important to review patient factors and clinical context; immunosuppression (transplant, Cushing's, malignancy, etc.) would likely warrant preoperative antibiotics
  - some evidence suggests role in breast surgery
  - important that redosing antibiotics is performed if surgery is longer than the half-life of antibiotics
- reserve postoperative antibiotics for treatment of suspected or documented intra-abdominal infection
- normothermia (maintain patient temperature 36-38°C in the OR)
- hyperoxygenation (consider FiO_2 of 80% in OR)
- chlorhexidine-alcohol wash of surgical site
- hair removal should not be performed unless necessary; if so, clipping superior to shaving done at the time of surgery
- consider delayed primary closure of incision for contaminated wounds
- use sterile closing tray for laparotomy

Clinical Features

- typically fever POD #5-8 (*Streptococcus* and *Clostridium* can present in 24 h)
- localized pain, blanchable erythema, induration, purulent discharge, and warmth
- complications: fistula, sinus tracts, sepsis, abscess, suppressed wound healing, superinfection, spreading infection to myonecrosis or fascial necrosis (necrotizing fasciitis), wound dehiscence, evisceration, and hernia

Complication	Laboratory/Imaging Tests
Wound Complication	Wound culture, CBC, CT scan
Fever	CBC, electrolytes, glucose, creatinine, BUN, U/A, CXR, urine/blood/sputum and wound culture if applicable
Respiratory Distress	EKG, echo, CXR, ABG, CT-angiography of the chest
AKI/Oliguria	Electrolytes, glucose, creatinine, BUN, U/A with microscopy, urine electrolytes, EKG, renal U/S
Hypotension	CBC, electrolytes, glucose, creatinine, BUN, lactate, ABG, ACTH stimulation testing, cortisol level, and coagulation studies
Ileus	Electrolytes, glucose, creatinine, BUN, AXR
Stress Ulcer	CBC, upper endoscopy

Preoperative Skin Antiseptics for Preventing Surgical Wound Infections after Clean Surgery
Cochrane DB Syst Rev 2015;4:CD003949
Purpose: To determine whether preoperative skin antisepsis prior to clean surgery prevents surgical-site infection (SSI) and to compare the effectiveness of other antiseptics.
Methods: Systematic review of RCTs part of the Cochrane Wounds Group Specialised Register and the Cochrane Central Register of Controlled Trials (CENTRAL). Main outcome was SSI. Secondary outcomes included quality of life, mortality, and resource use.
Results: 13 RCTs (n=2623 patients) were included that made 11 total comparisons between skin antiseptics. A single study found that 0.5% chlorhexidine solution in methylated spirits was significantly superior in preventing SSIs after clean surgery compared to alcohol-based povidone iodine solution. No other statistically significant differences were found.
Conclusions: Further research is warranted to determine the effectiveness of one antiseptic over the others at preventing SSI post clean surgery.

Primary vs. Delayed Primary Incision Closure in Contaminated Abdominal Surgery: A Meta-Analysis
J Surg Res 2019;239:22-30
Purpose: To determine if delayed primary incision closure (DPC) has lower rates of surgical site infections (SSI) and length of stay (LOS) compared to primary incision closure (PC) in contaminated abdominal surgery.
Methods: Systematic review and meta-analysis of RCTs in Medline, Embase, and Cochrane database between 1980-2017.
Results: 12 RCTs were included and analyzed. Using a fixed-effect model, DPC showed significantly reduced SSI with risk ratio of 0.64 (95% CI 0.51-0.79; P<0.0001) and reduced LOS with a mean difference of less than one day compared with PC. However, using a random-effect model, there was no significant difference in SSI or LOS.
Conclusions: DPC may be the preferential option in contaminated abdominal incisions, however higher quality research is required to provide a more comprehensive evidence base.

Treatment
- examination of the wound: inspect, compress adjacent areas, swab drainage for C&S and Gram stain
- reopen affected part of incision, drain, pack, heal by secondary intention in most cases
- for deeper or necrotizing infections, debride necrotic and non-viable tissue
- antibiotics and demarcation of erythema only if cellulitis or immunodeficiency

WOUND HEMORRHAGE/HEMATOMA

Risk Factors
- anticoagulant therapy, coagulopathies, thrombocytopenia, DIC, severe liver disease, myeloproliferative disorders, severe arterial HTN, and severe cough
- more common with transverse incisions through muscle due to vascularity of muscle
- more clinically relevant in small working spaces such as breast or thyroid surgery (airway edema/compression)

Clinical Features
- pain, swelling, discolouration of wound edges, and leakage
- rapidly expanding neck hematoma can compromise airway and is a surgical emergency: consider having a suture kit at bedside in all neck surgery in the event of having to open the wound emergently (most important treatment in this case is to protect the airway with intubation)

Treatment
- pressure dressing
- open drainage ± wound packing (large hematoma only)
- if significant bleeding, may need to re-operate to find source (often do not find a discrete source)

SEROMA
- fluid collection related to serous lymph drainage
- secondary to transection of lymph vessels
- increased infection risk if drained

Treatment
- observation
- consider pressure dressing ± needle drainage (this may increase infection risk)

WOUND DEHISCENCE
- disruption of a wound that was primarily closed, causing loss of barrier of skin or fascia

Risk Factors
- local: technical failure of closure, excessive tension on the wound, increased intra-abdominal pressure (e.g. COPD, ileus, bowel obstruction), hematoma, infection, poor blood supply, radiation, and transverse incision
- systemic: male, smoking, malnutrition (hypoalbuminemia, vitamin C deficiency), connective tissue diseases, immunosuppression, pulmonary disease, ascites, poor nutrition, steroids, chemotherapy, obesity, others (e.g. age, sepsis, and uremia)
- DM alone is not a risk factor
- when removing staples, those at high risk should have alternate staples removed first in a small area to ensure the fascia is intact before removing more (PRO TIP)

Clinical Features
- typically POD #1-3 or #7-10; most common presentation sign is serosanguinous (salmon-coloured) drainage from wound; erythema or leakage of enteric material
- ± evisceration
- palpation of wound edge: should normally feel a "healing ridge" from abdominal wall closure (raised area of tissue under incision)

Treatment
- place moist dressing over wound with binder around abdomen and transfer to OR
- may consider conservative management with debridement of fascial and/or skin margins
- evisceration (i.e. 'burst abdomen') is a surgical emergency: take patient for operative re-closure

INCISIONAL HERNIA
- a late complication of fascial dehiscence and failure of fascial closure; GI contents are still contained within sack of peritoneum
  - hernia can develop 6-8 wk postoperatively due to poor wound healing and/or increased stress on abdominal wall
- symptoms aggravated by coughing or straining
- smaller fascial defects such as laparoscopic port sites have a higher risk of incarceration
- definitive treatment: surgical repair
  - large hernias that pose little risk of incarceration do not need to be repaired as minimal chance of bowel obstruction

Small Bites vs. Large Bites for Closure of Abdominal Midline Incisions (Stitch): A Double-Blind, Multicentre, Randomised Controlled Trial
Lancet 2015;386:1254-1260
Purpose: To compare the large bites suture technique with the small bites technique for fascial closure of midline laparotomy incisions.
Methods: RCT conducted at 10 hospitals in the Netherlands. Patients undergoing elective abdominal surgery randomized (1:1) to small or large bite technique. Primary outcome was incisional hernia occurrence.
Results: At one year follow-up, the large bites group had a greater incidence of incisional hernia occurrence than the small bites group (21% vs. 13%, respectively). Rates of adverse events did not differ between the groups.
Conclusion: Small bites suture technique is superior to the large bites technique for prevention of incisional hernia in midline incisions and is not associated with a higher rate of adverse events.

Urinary and Renal Complications

URINARY RETENTION
- may occur after any operation with general anesthesia or more commonly with spinal anesthesia
- more likely in older males with history of benign prostatic hyperplasia and patients on anticholinergics but can also happen in young, healthy patients

Clinical Features
- abdominal discomfort, palpable bladder, overflow incontinence, post-void residual urine volume >100 mL

Treatment
- in-and-out catheter to rest bladder, then trial of voiding
- often accompanied by an α-blocker such as tamsulosin (does not start working for 48 h)
- if postoperative retention: patients may need to be sent home with foley catheter and leg-bag (urometer) to follow-up within the week for trial-of-void

OLIGURIA/ANURIA

Etiology
- prerenal (e.g. hypovolemia due to transient renal hypoperfusion) vs. renal (e.g. ATN, acute interstitial nephritis (AIN), acute glomerulonephritis) vs. postrenal (e.g. urinary tract obstruction)
- most common postoperative cause is prerenal ± ischemic ATN
  - external fluid loss: hemorrhage, dehydration, and diarrhea
  - internal fluid loss: third-spacing due to bowel obstruction and pancreatitis

Clinical Features
- urine output <0.5 cc/kg/h (e.g. <450 cc in 75 kg patient in 12 h), increasing Cr and BUN

Treatment
- according to underlying cause; fluid deficit is treated with crystalloid (NS or RL)

Postoperative Dyspnea

- see *Respiratory Complications* and *Cardiac Complications, GS12*

Etiology
- respiratory: atelectasis, pneumonia/pneumonitis, pulmonary embolism (PE), ARDS, asthma, and pleural effusion
- cardiac: MI, arrhythmia, and CHF
- inadequate pain control

Respiratory Complications

ATELECTASIS
- comprises 90% of postoperative pulmonary complications

Risk Factors
- COPD, smoking, obesity, and elderly persons
- upper abdominal/thoracic surgery, oversedation, significant postoperative pain, and poor inspiratory effort

Clinical Features
- postoperative atelectasis may be asymptomatic or present as low-grade fever on POD #1, tachycardia, crackles, decreased breath sounds, bronchial breathing, and tachypnea

Treatment
- preoperative prophylaxis
  - smoking cessation (best if >8 wk preoperative)
- postoperative prophylaxis
  - incentive spirometry, deep breathing exercise, chest physiotherapy, and intermittent positive-pressure breathing
  - short-acting neuromuscular blocking agents
  - minimize use of respiratory depressive drugs, and ensure adequate pain control, and early ambulation

PNEUMONIA/PNEUMONITIS
- may be secondary to aspiration of gastric contents during anesthetic induction or extubation causing a chemical pneumonitis

Risk Factors
- aspiration: general anesthetic, decreased LOC, GERD, full stomach, bowel/gastric outlet obstruction + non-functioning NG tube, pregnancy, and seizure disorder
- non-aspiration: atelectasis, immobility, and pre-existing respiratory disease

Clinical Features
- productive cough and fever
- tachycardia, cyanosis, respiratory failure, and decreased LOC
- CXR: pulmonary infiltrate

Treatment
- prophylaxis: see atelectasis prophylaxis, preoperative NPO/NG tube, and rapid sequence anesthetic induction
- immediate removal of debris and fluid from airway
- consider endotracheal intubation and flexible bronchoscopic aspiration
- empiric IV antibiotics to cover oral nosocomial aerobes and anaerobes (e.g. piperacillin-tazobactam, cefepime + metronidazole)

PULMONARY EMBOLUS

Clinical Features
- unilateral leg swelling and pain (DVT as a source of PE), sudden onset dyspnea, pleuritic chest pain, tachycardia, and fever
- most commonly POD #8-10, but can occur anytime postoperatively, even after discharge
- diagnosis made by chest CT scan usually

Treatment
- initial treatment: IV heparin or subcutaneous LMWH, bridging to therapeutic anticoagulation is required for a minimum of 3 mo (usually 6 mo); for patients with cancer, or other risk factors for hypercoagulability, the duration of anticoagulation may be longer; severe cases may require endovascular thrombectomy and thrombolysis
- Greenfield (IVC) filter if contraindications to anticoagulation helps prevent worsening of PE
- prophylaxis: subcutaneous heparin (5000 units BID/TID; less preferred) or LMWH, compression stockings (TED™ Hose), and sequential compression devices

PULMONARY EDEMA

Etiology
- cardiogenic vs. noncardiogenic
- circulatory overload: excess fluid overload, left ventricular (LV) failure, shift of fluid from peripheral to pulmonary vascular bed, negative airway pressure, and alveolar injury due to toxins (e.g. ARDS)
  - more common with pre-existing cardiac disease
- negative pressure pulmonary edema due to inspiratory efforts against a closed glottis upon awakening from general anesthesia

New onset "asthma" and wheezing in the elderly is cardiogenic until proven otherwise

Clinical Features
- shortness of breath, crackles at lung bases, and CXR abnormal

Treatment (LMNOP)
- **L**asix® (furosemide)
- **M**orphine (decreases symptoms of dyspnea, venodilator, and afterload reduction)
- **N**itrates (venodilator)
- **O**xygen + non-invasive ventilation
- **P**osition (sit patient up)

RESPIRATORY FAILURE

Clinical Features
- dyspnea, cyanosis, and evidence of obstructive lung disease
- earliest manifestations - tachypnea and hypoxemia (RR >25, PO_2 <60)
- pulmonary edema and unexplained decrease in SaO_2

Treatment
- ABCs, O_2, ± positive pressure ventilation, and intubation
- bronchodilators and diuretics to treat CHF
- adequate blood pressure to maintain pulmonary perfusion
- if these measures fail to keep PaO_2 >60, consider ARDS (see Respirology, R24)

Cardiac Complications

- abnormal ECGs common in postoperative period (compare to preoperative ECG)
- common arrhythmias: supraventricular tachycardia, atrial fibrillation (secondary to fluid overload, PE, and MI)

MYOCARDIAL INFARCTION
- see Cardiology and Cardiac Surgery, C9
- surgery increases risk of MI
- incidence
  - 0.5% in previously asymptomatic men ages >50
  - 40-fold increase in men ages >50 with previous MI

Risk Factors
- preoperative HTN, CHF
- previous MI (highest risk ≤6 mo, but risk never returns to baseline)
- increased age
- intraoperative hypotension
- operations >3 h
- angina

Clinical Features
- majority of cases on day of operation or POD #3-4 (shifting of third space fluid back into intravascular compartment)
- often silent without chest pain, may only present with new-onset CHF (dyspnea), arrhythmias, and hypotension

Intra-Abdominal Abscess

Definition
- collection of pus walled-off from rest of peritoneal cavity by inflammatory adhesions and viscera

Etiology
- usually polymicrobial: Gram-negative bacteria, and anaerobes
  - consider Gram-positives if coexisting cellulitis

Risk Factors
- emergency surgery and contaminated OR
- GI surgery with anastomotic leak
- poor healing risk factors (DM, poor nutrition, etc.)
- may occur POD #3 after laparotomy when third space fluid redistribution occurs

Clinical Features
- manifests at least 5-7 d after surgery. Cannot manifest earlier as it takes time to form collection
- persistent spiking fever, dull pain, and weight loss
- peritoneal signs if abscess perforation and secondary peritonitis
- leukocytosis or leukopenia (immunocompromised and elderly)
- coexisting effusion (pleural effusion with subphrenic abscess)
- mass is often difficult to palpate
- common sites if disseminated peritonitis: pelvis, Morrison's pouch (space between kidney and liver), subphrenic, paracolic gutters, lesser sac or local peritonitis: peri-appendiceal, post-surgical anastomosis, diverticular, and psoas

Investigations
- CBC, blood cultures x2
- CT ± IV and water-soluble contrast
- C&S from drain

Treatment
- drain placement by interventional radiology (preferred), laparoscopy, and open drainage
- subsequent antibiotic coverage; ceftriaxone + metronidazole or piperacillin-tazobactam (Pip-Tazo)

Paralytic Ileus

- see *Paralytic Ileus, GS31*

Delirium

- see Psychiatry, PS23 and Neurology, N21

Thoracic and Foregut Surgery

Approach to the Solitary Pulmonary Nodule

- see Medical Imaging, MI8

Definition
- lesion up to 3 cm, which may or may not be calcified and is surrounded by normal lung
- can be benign or malignant

Differential Diagnosis of Upper GI Symptoms

GI Causes	Non-GI Causes
Cholelithiasis	MI
Diverticulitis	Angina
Peptic ulcer	Pericarditis
Achalasia	
Pancreatitis	
GERD	
Gastritis	
Hiatus hernia	

Horner has a MAP of the Coast
A Pancoast tumour compresses the cervical sympathetic plexus causing Horner's syndrome:
Miosis
Anhydrosis
Ptosis

Differential of an Anterior Compartment Mass

4 Ts
Thymoma
Thyroid enlargement (goitre)
Teratoma
Tumours (lymphoma, parathyroid, angiomatous)

Table 6. Differential Diagnosis for Benign vs. Malignant Solitary Nodule

Benign (70%)	Malignant (30%)	
Infectious granuloma (histoplasmosis, coccidiomycosis, TB, atypical mycobacteria) - most common **Other infections** (bacterial abscess, PCP, aspergilloma) **Benign neoplasms** (hamartoma, lipoma, fibroma) **Vascular** (AV malformation, pulmonary varix) **Developmental** (bronchogenic cyst) **Inflammatory** (granulomatosis with polyangiitis, rheumatoid nodule, sarcoidosis, amyloidosis) **Other** (infarct, pseudotumour, rounded atelectasis, lymph nodes, amyloidoma)	**Bronchogenic carcinoma** Adenocarcinoma SCC Large cell carcinoma Small cell carcinoma Small cell lung cancer	**Metastatic lesions** Breast Head and neck Melanoma Colon Kidney Sarcoma Germ cell tumours

Investigations

- CXR: always compare with previous CXR
- CT and contrast-enhanced CT of thorax
- biopsy (bronchoscopic or percutaneous) or excision (thoracoscopy): if clinical and radiographic features do not help distinguish between benign or malignant lesion
  - if at risk for lung cancer, biopsy may be performed regardless of radiographic features
  - if a biopsy is non-diagnostic, whether to observe, re-biopsy, or resect will depend on the level of suspicion
- watchful waiting: repeat CT scan at 3, 6, 12 mo depending on nodule characteristics and patient risk
- PET scan can narrow the differential diagnosis

Table 7. CT Characteristics of Benign vs. Malignant Solitary Nodule

Parameters	Benign	Malignant
Size	Nodule (<3 cm)	Mass (>3 cm)
Borders	Smooth or lobulated	Irregular or spiculated
Features	Calcified pattern: diffuse, central, laminated, "popcorn" pattern if hamartoma, usually no cavitation; if cavitating, wall is smooth and thin, no other lung pathology	Usually not calcified; if calcified, pattern is eccentric, stippled, no satellite lesions, cavitation with thick wall, may have pleural effusions, lymphadenopathy
Doubling Time	Doubles in <20 or >400 d	Doubles between 20 and 400 d

Table 8. Evaluation of a Solitary Pulmonary Nodule

SOLID NODULES			
Nodule Type	**Size <6 mm (<100 mm^2)**	**Size 6-8 mm (100-250 mm^2)**	**Size >8 mm (>250 mm^2)**
Single			
Low-Risk	No routine follow-up	CT at 6-12 mo, then consider CT at 18-24 mo	Consider CT a 3 mo, PET/CT or tissue sampling
High-Risk	Optional CT at 12 mo	CT at 6-12 mo, then at 18-24 mo	Consider CT a 3 mo, PET/CT or tissue sampling
Multiple			
Low-Risk	No routine follow-up	CT at 3-6 mo, then consider CT at 18-24 mo	CT at 3-6 mo, then consider CT at 18-24 mo
High-Risk	Optional CT at 12 mo	CT at 3-6 mo, then at 18-24 mo	CT at 3-6 mo then at 18-24 mo
SUBSOLID NODULES			
Nodule Type	**Size <6 mm (<100 mm^2)**	**Size ≥6 mm (>100 mm^2)**	
Single			
Ground Glass	No routine follow-up	CT at 6-12 mo to confirm persistence then CT every 2 yr until 5 yr	
Part Solid	No routine follow-up	CT at 3-6 mo to confirm persistence If unchanged and solid component remains <6 mm, annual CT should be performed for 5 yr	
Multiple	CT at 3-6 mo. If stable consider CT at 2 and 4 yr	CT at 3-6 mo Subsequent management based on the most suspicious nodule(s)	

Adapted from: MacMahon H, Naidich DP, Goo JM, et al. Guidelines for Management of Incidental Pulmonary Nodules Detected on CT Images. The Fleischner Society 2017. Radiology Journal. doi:10.1148/radiol.2017161659. Feb 23 2017.

Lung Cancer

Classification

- lung tumours can be classified as:
  - primary or secondary
  - benign or malignant
  - endobronchial or parenchymal
- bronchogenic carcinoma (epithelial lung tumours) are the most common type of primary lung tumour (other types make up less than 1%)
  - small cell lung cancer (SCLC): 10-15%

- non-small-cell lung cancer (NSCLC): 85-90%
  - SCC: arise from the proximal respiratory epithelium
  - adenocarcinoma: incidence is increasing; most common subtype in nonsmokers
    - mucinous adenocarcinoma: grows along the alveolar wall in the periphery; may arise at sites of previous lung scarring
  - large cell carcinoma
- benign epithelial lung tumours can be classified as papillomas or adenomas

Table 9. Characteristics of Lung Cancer

Cell Type	Percentage of Lung Cancer	Correlation with Smoking	Location	Histology	Metastasis	5 Yr Survival Rates
SCLC	10-15%	Strong	Central	Oat cell, neuroendocrine	Disseminated at presentation Origin in endobronchial cells	10-13% limited stage, 1-2% extensive stage
Adenocarcinoma	M: 35% F: 40%	Moderate	Peripheral	Papillary, lepidic, acinar, mucinous, solid	Early, distant	70% early stage, 7% advanced stage
SCC	30%	Strong	Central	Keratin, intercellular bridges	Local invasion and distant spread, may cavitate	47% early stage, 6% advanced stage
Large Cell Carcinoma	10-15%	Strong	Peripheral	Anaplastic, undifferentiated	Early, distant	53% early stage, 5% advanced stage

US Mortality Files, National Center for Health Statistics, CDC

Canadian Task Force on Preventive Health (2016)
Screening with low-dose CT recommended for high-risk patients only:
- 55-74 yr
- ≥30 pack-yr smoking Hx
- Current smoker or quit within last 15 yr
- Annual screening low-dose CT up to 3 yr

Risk Factors

- cigarette smoking: the relative risk of developing lung cancer is 10-30 times higher for smokers than for nonsmokers
- risk of lung cancer increases with number of cigarettes smoked per day (linear) and duration of smoking (exponential)
- other risk factors: cigar smoking, pipe smoking, second-hand smoke, asbestos without smoking (relative risk is 5), asbestos with smoking (relative risk is 92), metals (e.g. chromium, arsenic, nickel), radon gas, ionizing radiation, and genetics

Clinical Features

- may be due to primary lesion, metastasis, or paraneoplastic syndrome
- primary lesion
  - cough (75%): beware of chronic cough that changes in character
  - dyspnea (60%)
  - chest pain (45%)
  - hemoptysis (35%)
  - other pain (25%)
  - clubbing (21%)
  - constitutional symptoms: anorexia, weight loss, fever, and fatigue
- metastasis
  - lung, hilum, mediastinum, pleura: pleural effusion, atelectasis, wheezing, post-obstructive pneumonia
  - pericardium: pericardial effusion, pericardial tamponade
  - esophageal compression: dysphagia
  - phrenic nerve: paralyzed diaphragm, dyspnea
  - recurrent laryngeal nerve: hoarseness
  - superior vena cava syndrome
    - obstruction of SVC causing neck and facial swelling
    - other symptoms: dyspnea, cough, hoarseness, tongue swelling, epistaxis, and hemoptysis
    - physical findings: dilated neck veins, increased number of collateral veins covering the anterior chest wall, cyanosis, edema of the face, arms, and chest, Pemberton's sign (facial flushing, cyanosis, and distension of neck veins upon raising both arms above head)
    - milder symptoms if obstruction is above the azygos vein
  - lung apex (Pancoast tumour): Horner's syndrome, brachial plexus palsy (most commonly C8 and T1 nerve roots)
  - rib and vertebrae: erosion, pain
  - distant metastasis to brain, bone, liver, and adrenals
- paraneoplastic syndromes
  - most often associated with SCLC

Malignant lung tumours are the most common cause of cancer mortality in both men and women worldwide

Endobronchial Ultrasound (EBUS)

Allows visualization of peri-bronchial structures and lung lesions

Allows for guided biopsies of lymph nodes and tumours

Used for diagnosis and staging

Table 10. Paraneoplastic Syndromes

System	Clinical Features	Associated Malignancy
Skeletal	Clubbing, hypertrophic pulmonary osteoarthropathy (HPOA)	Non-small cell lung cancer (NSCLC)
Dermatologic	Acanthosis nigricans Dermatomyositis	Lung cancer
Endocrine	Hypercalcemia (osteolysis or PTHrP) Hypophosphatemia Hypoglycemia Cushing's syndrome (ACTH) Carcinoid syndrome SIADH	SCC SCC Sarcoma Small cell lung cancer (SCLC) Bronchial carcinoid SCLC
Neuromyopathic	Lambert-Eaton syndrome Polymyositis Subacute cerebellar degeneration Spinocerebellar degeneration Peripheral neuropathy	SCLC
Vascular/Hematologic	Nonbacterial endocarditis Trousseau's syndrome (migratory thrombophlebitis) DIC	Lung cancer NSCLC
Renal	Nephrotic syndrome	Lung carcinoma

Investigations

- initial diagnosis
  - imaging: CXR, CT chest + abdomen, PET scan
  - biopsy: bronchoscopy, EBUS, CT-guided percutaneous needle biopsy
- staging workup
  - TNM staging system: T – primary tumour (size); N – regional lymph nodes; M – distant metastasis
  - blood work: electrolytes, LFTs, calcium, ALP
  - imaging: CXR, CT thorax and abdomen, PET scan, bone scan (-in confirmed stage 4 cancer), neuroimaging (MRI Brain)
  - invasive: bronchoscopy (EBUS), mediastinoscopy, VATS

Table 11. SCLC vs. NSCLC

	Stage	Definition	Treatment	Median Survival
SCLC	Limited stage	Confined to single radiation port (one hemithorax and regional lymph nodes)	Radiation ± chemotherapy ± prophylactic to brain	1-2 yr (12 wk without treatment)
	Extensive stage	Extension beyond a single radiation port	Chemotherapy	6 mo (5 wk without treatment)
	Stage	**TNM**	**Treatment**	**5 Yr Survival (%)***
NSCLC	0	TisN0M0	1st line is complete surgical resection (VATS or open thoracotomy) with possible postoperative adjuvant chemotherapy with stage IB and stage II; radiotherapy for non-surgical candidates	
	IA1	T1aN0M0		90-92
	IA2	T1bN0M0		83-85
	IA3	T1cN0M0		77-80
	IB	T2aN0M0		68-73
	IIA	T2bN0M0		60-65
	IIB	T3N0M0 or T1N1M0 or T2N1M0		53-56
	IIIA	T4N0M0 or T4N1M0 or T3M1N0 or T1N2M0 or T2N2M0	Combined modality approach (chemo ± radiation, and sometimes surgical resection)	36-41
	IIIB	T3N2M0 or T4M2N0 or T1N3M0 or T2N3M0		24-26
	IIC	T3N3M0 or T4N3M0		12-13
	IVA	T1-4N0-3M1a-1b	Systemic therapy or molecularly targeted therapy or symptom-based palliative management (radiation); isolated metastasis may be resected	10
	IVB	T1-4N0-3M1c		0

* Depends on clinical vs. pathologic stage Refer to AJCC Cancer Staging Manual, 8th ed. 2017 for complete TNM classification

Treatment

- options include surgery, radiotherapy, ablation, chemotherapy, and palliative care for end-stage disease
- surgery not usually performed for SCLC since it is generally non-curable
- contraindications for surgery
  - spread to contralateral mediastinal lymph nodes or distant sites
    - patients with potentially resectable disease must undergo mediastinal node sampling since CT thorax is not accurate in 20-40% of cases
  - poor pulmonary status (e.g. unable to tolerate resection of lung)
    - postoperative estimated FEV $_1$and DLCO must be at least 40% of predicted to tolerate surgery
- chemotherapy (used in combination with other treatments)
  - common agents: cisplatin-vinorelbine (standard of care), etoposide, ifosfamide, vincristine, anthracyclines, paclitaxel, irinotecan, gefitinib (an endothelial growth factor receptor inhibitor)
  - pembrolizumab, a PD-1 monoclonal antibody is used in those with tumour PD-L1 levels >50%; for those with PD-L1 levels <50%, combination of doublet chemotherapy and pembrolizumab is initiated

2/3 of primary lung cancer is found in the upper lung; 2/3 of metastases occur in the lower lung (hematogenous spread secondary to increased blood flow to the base of the lung)

Prevention
Smoking cessation
Avoidance of exposures
Early detection

Terminology
- "Nodule" <3 cm
- "Mass" >3 cm

Mutations in endothelial growth factor receptor are more common in non-smoking patients with adenocarcinoma

Corona Radiata Sign on Chest CT

Fine striations that extend linearly from a nodule in a spiculated fashion

Highly associated with malignancy

Carcinoids

Early onset (40-60 yr)

Most are central and can produce symptoms and signs of bronchial obstruction

Hemoptysis is present in ~50% of cases

Assuming adequate pulmonary function, surgical resection (i.e. segmentectomy, wedge resections, and lobectomy) is the preferred treatment approach

- targeted therapies such as EGFR tyrosine kinase inhibitors and ALK tyrosine kinase inhibitors are used if tumour tests positive for these mutations
- complications
  - acute: tumour lysis syndrome, infection, bleeding, myelosuppression, hemorrhagic cystitis (cyclophosphamide), cardiotoxicity (doxorubicin), renal toxicity (cisplatin), peripheral neuropathy (vincristine)
  - chronic: neurologic damage, leukemia, additional primary neoplasms

Pleura, Lung, and Mediastinum

- see Respirology, R23

Hamartomas

10% of benign lung lesions

Composed of tissues normally present in lung (fat, epithelium, fibrous tissue, and cartilage), but they exhibit disorganized growth

Peak incidence is age 60, more common in men

Usually peripheral and clinically silent

CXR shows clustered "popcorn" pattern of calcification (pathognomonic for hamartoma)

Peripheral small hamartomas can generally be observed with occasional follow-up to monitor growth; symptomatic endobronchial hamartomas are removed via rigid transbronchial resection

Complicated Parapneumonic Effusion

Definition
- persistent bacteria in the pleural space but fluid is non-purulent
- neutrophils, pleural fluid acidosis (pH<7.20), low glucose (<40 mg/dL)
- often no bacteria grown since rapidly cleared from pleural space

Clinical Features
- fever, pleuritic chest pain, dyspnea, and sputum production

Treatment
- antibiotics depending on Gram stain and culture
- chest tube drainage

Empyema

Definition
- bacteria in pleural space or an effusion with organisms seen on a Gram stain or culture (e.g. pleural fluid is grossly purulent in advanced stage empyema)
- positive culture is not required for diagnosis

Etiology
- contiguous spread from lung infection (most commonly anaerobes) or infection through chest wall (e.g. trauma, surgery)

Clinical Features
- fever, pleuritic chest pain, dyspnea, and sputum production

Investigations
- CT chest
- thoracentesis
  - PMNs (lymphocytes in TB) ± visible organisms on Gram stain

Treatment
- antibiotic therapy for at least 4-6 wk (rarely effective alone)
- complete pleural drainage with chest tube
- if loculated, more difficult to drain – may require surgical drainage with VATS, or fibrinolysis (surgical or tPA/DNAse) to allow lung re-expansion (decortication)

Pneumothorax

Definition
- presence of air in the pleural space
- can be classified as:
  - primary or secondary
  - open or closed
  - simple or tension or occult (only visible on CT scan)

Pathophysiology
- entry of air into pleural space raises intrapleural pressure causing partial or complete lung deflation

Etiology
- traumatic: penetrating or non-penetrating chest injuries
- iatrogenic: central venous catheter, thoracentesis, mechanical ventilation with barotrauma, surgery

- spontaneous: no history of trauma or other underlying cause
  - primary (no underlying lung disease)
    - spontaneous rupture of apical subpleural bleb (pockets of air) of lung into pleural space
    - smoker, male, family history, Marfan's syndrome
  - secondary (underlying lung disease)
    - rupture of subpleural bleb in the pleural space which can migrate along bronchioalveolar bronchoalveolar sheath to the mediastinum then to the intrapleural space
    - necrosis of lung tissue adjacent to pleural surface
    - pneumonia, abscess, PCP, lung cancer, COPD, CF, TB, lymphangioleiomyomatosis (LAM), pulmonary Langerhans cell histiocytosis (PLCH), lung metastasis (e.g. sarcoma)

Clinical Features
- can be asymptomatic
- acute-onset pleuritic chest pain, dyspnea
- tachypnea, tachycardia
- tracheal deviation (contralateral deviation in tension pneumothorax)
- shock (in tension pneumothorax)
- ipsilateral diminished chest expansion
- decreased tactile/vocal fremitus
- hyperresonance
- ipsilateral diminished breath sounds

Investigations
- CXR
  - small: separation of visceral and parietal pleura seen as fine crescentic line parallel to chest wall at apex
  - large: decreased density and decreased volume of lung on side of pneumothorax
  - see Medical Imaging, MI4 and MI9

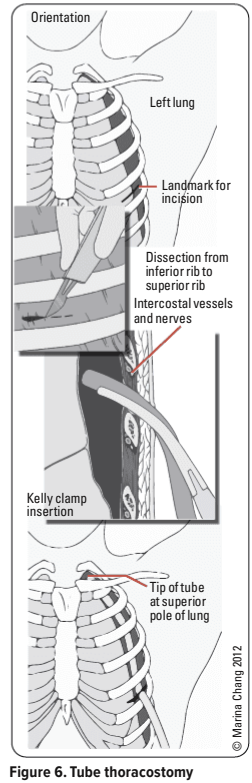
Tube thoracostomy can be completed under U/S guidance

Treatment
- primary spontaneous pneumothorax
  - stable, small (<3 cm), minimal symptoms: observation + O_2
  - symptomatic or large (>3 cm): aspiration or chest tube
  - unstable/tension pneumothorax: needle decompression then chest tube, VATS bullectomy, and pleurodesis if unsuccessful (25-50%)
- secondary spontaneous pneumothorax
  - stable, small (<3 cm), minimal symptoms: observation + O_2
  - symptomatic, large, or unstable: chest tube and VATS pleurodesis with or without bullectomy if unsuccessful

Tube Thoracostomy

Indications
- to drain abnormal air or fluid collections in the pleural space
  - hemothorax, pleural effusion, chylothorax, and empyema
  - pneumothorax, if:
    - large or progressive
    - patient is on mechanical ventilation
    - bronchopleural fistula
    - tension pneumothorax
- to treat symptomatic and/or recurrent pleural effusion
  - see Respirology, R24
  - for long-term drainage of malignant effusions use: 1. Tunneled pleural catheter; 2. Pleural drainage and Talc pleurodesis
  - via facilitation of pleurodesis - obliteration of the pleural space by instilling talc to cause fusion of parietal and visceral pleura

Complications
- overall complications are rare (1-3%)
- malposition (most common complication), especially by inexperienced operators
  - tubes may be placed outside the pleural cavity in the chest wall, or below the diaphragm
- bleeding (anticoagulation is a relative contraindication)
- local infection, empyema
- perforation of lung parenchyma, liver, spleen or vasculature
- risk of re-expansion pulmonary edema when large volumes of fluid are drawn off quickly (>1.0-1.5 L)



Orientation
Left lung
Landmark for incision
Dissection from inferior rib to superior rib
Intercostal vessels and nerves
Kelly clamp insertion
Tip of tube at superior pole of lung
© Marina Chang 2012

Figure 6. Tube thoracostomy

Lung Transplantation

Conditions Leading to Transplantation
- obstructive: chronic acquired lung disease (e.g. COPD), CF, and emphysema due to α-1 antitrypsin deficiency
- restrictive interstitial lung disease: IPF, hypersensitivity pneumonitis
- vascular: idiopathic pulmonary arterial HTN (IPAH), secondary pulmonary HTN, and Eisenmenger's syndrome
- other: sarcoidosis, lymphangioleiomyomatosis, and pulmonary Langerhans cell histiocytosis

Clinical Indications
- transplantation should be considered for patients with advanced lung disease refractory to maximal medical or surgical therapy
- patients who are symptomatic during activities of daily living and have risk of death >50% over the next 2 yr

Criteria for Transplantation
- lung allocation score based on: 1) post-transplant survival measure, and 2) waiting list urgency measure
- transplant benefit = post-transplant survival (days) – waitlist survival (days)

Absolute Contraindications
- uncontrolled or untreatable pulmonary or extrapulmonary infection
- active TB infection
- malignancy in the last 2 yr
- dysfunction of vital organs including glomerular filtration rate of <40 mL/min/1.73 m^3, stroke within 30 d, acute liver failure or cirrhosis, acute coronary syndrome within 30 d or heart disease not amenable to revascularization, and untreatable hematologic disorders
- active cigarette smoking
- BMI ≥35 kg/m^2
- unresolved psychosocial problems or non-adherence to medical therapy
- smoking
- absence of social support system

Relative Contraindications
- ages >70 yr and low physiologic reserve
- BMI 30-34.9 kg/m^2
- limited functional status including severe malnutrition or osteoporosis
- HIV infection, HBV infection
- alcohol (required to stay within healthy drinking guidelines)

Postoperative Complications
- primary graft dysfunction
- airway anastomotic complications (bronchial necrosis and dehiscence, tracheobronchomalacia, stenosis)
- chronic lung allograft dysfunction (bronchiolitis obliterans syndrome and restrictive allograft syndrome)
- infectious complications (bacterial, fungal, CMV, community-acquired respiratory viruses, and mycobacteria)
- malignancy (non-melanoma skin cancer, post-transplant lymphoproliferative disorders, colon, breast, Kaposi's sarcoma, and bladder)

Prognosis
- median survival for all adult recipients: 6.5 yr; bilateral transplant survival higher than single (7.6 vs. 4.7 yr, respectively)
- 1 yr survival: COPD > IPF > IPAH
- 10 yr survival: CF, α-1 antitrypsin deficiency > IPAH > COPD, IPF

Chronic Obstructive Pulmonary Disease

- see Respirology, R9

Treatment
- indications for surgical management
  - dyspnea despite maximal medical therapy and pulmonary rehabilitation
  - CT showing hyperinflation and heterogeneously distributed emphysema predominant in the upper lung zone
  - may be used as a bridging procedure to lung transplantation

- contraindications
  - ages >75, cigarette smoking within the prior 6 mo, higher risk of surgical mortality (e.g. severe CAD or HF)
  - homogeneously distributed emphysematous changes without areas of preserved lung tissue
  - severe cachexia or obesity, chest wall deformity, or pulmonary HTN (PA systolic pressure >45 mmHg)
  - diffusing capacity of lung for carbon monoxide <20% of predicted, $PaCO_2$ >60 mmHg, PaO_2 <45 mmHg
- surgical procedures
  - lung volume reduction surgery: wedge excision of emphysematous tissue
  - bilateral or unilateral, thoracotomy or VATS (preferred)

Complications of Treatment
- arrhythmias, pneumonia (may require reintubation and mechanical ventilation), prolonged air leak from chest tube

Prognosis
- worse early mortality but better exercise capacity and quality of life with LVRS

Mediastinal Masses

Definition
- mediastinum: bound by the thoracic inlet, diaphragm, sternum, vertebral bodies, and the pleura
- can be broken down into 3 compartments: anterior, middle, and posterior

Etiology and Pathophysiology
- diagnosis is aided by location and patient's age
- anterior compartment: more likely to be malignant
  - "Four Ts" (see sidebar), lymphadenopathy, lipoma, pericardial cyst, goitre, and ascending aortic aneurysm thymic tumours/cysts
- middle compartment
  - pericardial cyst, bronchogenic cyst/tumour, lymphadenopathy, aortic aneurysm
- posterior compartment
  - neurogenic tumours, meningocele, enteric cysts, lymphadenopathy, diaphragmatic hernias, esophageal tumours, aortic aneurysm

Clinical Features
- 50% asymptomatic (mainly benign); when symptomatic, 50% are malignant
- chest pain, cough, dyspnea, recurrent respiratory infections
- hoarseness, dysphagia, Horner's syndrome (see sidebar), facial/upper extremity edema (SVC compression)
- paraneoplastic syndromes (e.g. myasthenia gravis (thymomas))

Investigations
- CXR (compare to previous)
- CT with contrast (anatomic location, density, relation to mediastinal vascular structures)
- MRI: specifically indicated in the evaluation of neurogenic tumours
- echocardiogram: best for assessment of structures in close proximity to the heart and pericardium
- radionuclide scanning: ^{131}I (for thyroid), gallium (for lymphoma), PET/CT
- biochemical studies: thyroid function, serum calcium, phosphate, PTH, AFP, β-hCG, LDH
- biopsy (mediastinoscopy, bronchoscopy, and EBUS, percutaneous needle aspiration)

Management
- excision – symptomatic benign mass that is enlarging or a mass with concerns for malignancy
- resect bronchogenic cysts and localized neurogenic tumours via VATS or open surgery
- diagnostic biopsy rather than major operation if mass is likely to be a lymphoma, germ cell tumour, or unresectable invasive malignancy
- no biopsy if AFP, β-hCG, LDH elevated – pathognomonic for germ cell tumour

Differential of an Anterior Compartment Mass

4 Ts
Thymoma
Thyroid enlargement (goitre)
Teratoma
Tumours (lymphoma, parathyroid, esophageal, angiomatous)

Mediastinal Components
Anterior: sternum to pericardium and great vessels. Includes: thymus, extra-pericardial aorta and branches, great veins, lymphatic tissues
Middle: pericardium (anteriorly), posterior pericardial reflection, diaphragm, thoracic inlet. Includes: heart, intrapericardial great vessels, trachea
Posterior: posterior pericardial reflection, posterior border of vertebral bodies, first rib to the diaphragm. Includes: esophagus, vagus nerve, thoracic duct, sympathetic chain, azygous venous system

Masaoka Staging System
Stage I: completely encapsulated
Stage II: invasion beyond capsule
Stage III: into another organ
Stage IVa: pleural/pericardial mets
Stage IVb: hematogenous/lymphatic mets

Thymoma

Definition
- rare neoplasms in thymus, located in anterior mediastinum

Epidemiology
- patients between 40 and 60 yr
- M=F
- no known risk factors, strong association with myasthenia gravis and other paraneoplastic syndromes

Clinical Features
- frequently asymptomatic: incidental finding on imaging
- symptoms related to tumour size and location (chest pain, SOB, cough, and phrenic nerve palsy)
- DDx includes intrathoracic goitre, lymphoma, and other anterior mediastinal tumours (see *Mediastinal Masses, GS20*)

Investigations
- CT chest (and/or MRI): assess resectability
- germ cell tumour markers (β-hCG, AFP, LDH), thyroid function, acetylcholinesterase antibodies (to rule out myasthenia gravis), and PFTs
- Masaoka staging system widely used

Treatment
- for patients with resectable disease
  - surgical resection of the thymoma and the thymus via median sternotomy or VATS depending on the size
  - ± postoperative radiation based on Masaoka staging
    - radiation considered for stage II/III disease
- for potentially unresectable disease (i.e. invasion into heart and great vessels) or non-surgical patients
  - definitive or palliative chemo and radiation therapy
- re-evaluation if debulking procedure feasible in situations where preoperative chemo- and radiation therapy is offered
- common chemotherapy regimens include: 1) cyclophosphamide, doxorubicin, and cisplatin, or 2) cisplatin and etoposide

Prognosis
- depends upon stage of disease and resectability
- generally slow-growing tumours and have good prognosis

Esophageal Carcinoma

Epidemiology
- M:F=3:1
- onset 50-60 yr
- upper (20-33%), middle (33%), and lower (33-50%)
- main types
  - most common worldwide: SCC in upper 2/3 of esophagus
  - most common in Western countries: adenocarcinoma in lower 1/3 of esophagus

Risk Factors
- SCC
  - underlying esophageal disease such as strictures, diverticula, and achalasia
  - smoking, alcohol, and hot liquids
  - more common in Black and Asian populations
- adenocarcinoma
  - Barrett's esophagus (most important), smoking, obesity (increased reflux), and GERD
  - more common in White populations

Clinical Features
- progressive dysphagia (mechanical): first solids then liquids, then saliva
- odynophagia then constant pain
- constitutional symptoms
- regurgitation and aspiration (aspiration pneumonia)
- hematemesis and anemia
- direct, hematogenous, or lymphatic spread
  - trachea (coughing), recurrent laryngeal nerves (hoarseness, vocal paralysis), aortic, liver, lung, bone, celiac, and mediastinal nodes

Investigations and Staging
- barium swallow: shows narrowing – suggestive but not diagnostic
- endoscopic biopsy to assess location, resectability, and confirm diagnosis
- both SCC and adenocarcinoma use TNM staging system but have separate stage groupings according to histology
- endoscopic U/S (EUS)
  - visualize local disease
  - regional nodal involvement (number of nodes may be more important than location)
- bronchoscopy and laryngoscopy
  - rule out airway invasion in tumours of the upper and middle esophagus
- full metastatic workup (CXR, bone scan, CT head, CT chest/abdomen/pelvis, and LFTs, etc.)
- PET scan more sensitive than CT in detecting metastatic disease

Treatment
- if early stage (non-transmural and without evidence of nodal disease)
  - endoscopic mucosal resection can be considered for early mucosal cancer or high-grade dysplasia
  - esophagectomy (transthoracic or trans-hiatal approach) and lymphadenectomy
    - anastomosis in chest or neck
    - stomach is used for reconstruction; colon is rarely used
- if locally advanced (locally invasive disease or nodal disease on CT or EUS)
  - multimodal therapy
    - concurrent external beam radiation and chemotherapy (cisplatin and fluorouracil)
    - possibility of curative esophagectomy after chemoradiation if unable to tolerate multimodal therapy or if highly advanced disease, consider radiotherapy, brachytherapy, or endoscopic dilatation/stenting/laser ablation for palliation
- if present with distant metastatic disease, treat with systemic therapy and treat symptoms (esophageal stent or radiation)

Prognosis
- TNM status - usually poor because presentation is usually at advanced stage

OTHER DISORDERS
- esophageal motor disorders (see Gastroenterology, G8)
- esophageal varices (see Gastroenterology, G9)
- Mallory-Weiss tear (see Gastroenterology, G30)

Esophageal Perforation

Etiology
- iatrogenic (most common)
  - endoscopic, dilatation, biopsy, intubation, operative, and NG tube placement (rare)
- barogenic
  - trauma
  - repeated, forceful vomiting (Boerhaave's syndrome)
  - other: convulsions, defecation, or labour (rare)
- ingestion injury
  - foreign body or corrosive substance
- carcinoma
- penetrating trauma

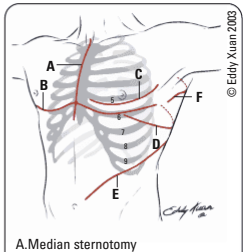
Clinical Features
- neck or chest pain
- fever, tachycardia, hypotension, dyspnea, and respiratory compromise
- subcutaneous emphysema, pneumothorax, pleural effusion, voice changes, and hematemesis

Investigations
- CXR: subcutaneous emphysema, pneumothorax, pneumomediastinum, pleural effusion, subdiaphragmatic air, and widened mediastinum
- CT chest with oral and IV contrast: pneumomediastinum, pleural effusion, pneumothorax, contrast in the chest, and subcutaneous emphysema
- contrast esophagram
  - Gastrografin® (water-soluble contrast) upper GI study is the first choice
  - if negative, followed by dilute barium upper GI study: contrast extravasation

Treatment
- supportive if rupture is contained (see sidebar Cameron's Criteria)
- NPO, antibiotics, IV fluids, percutaneous drainage of mediastinal collections/abscess if needed, enteral/parenteral feed, and repeat imaging
- surgical (preferred treatment in progressively deteriorating or toxic patient)
  - <24 h from perforation
    - primary closure of a healthy esophagus with buttressed intercostal muscle flap or resection of diseased esophagus
  - >24 h from perforation, non-viable esophagus, or morbidly toxic patient
    - diversion and exclusion followed by delayed reconstruction (i.e. esophagostomy proximally, close esophagus distally, and gastrostomy/jejunostomy for decompression/feeding)

Complications
- sepsis, abscess, fistula, empyema, mediastinitis, and death
- postoperative esophageal leak
- mortality 10-50% depending on timing of diagnosis, or etiology of the perforation, and underlying health and age of the patient

Cameron's Criteria for Conservative Management of Esophageal Perforation
- Perforation contained in mediastinum
- Contrast drains back into esophagus
- No signs of sepsis
- Minimal symptoms



A. Median sternotomy
B. Transverse thoracotomy (clam shell)
C. Anterolateral thoracotomy
D. Lateral thoracotomy
E. Thoracoabdominal thoracotomy
F. Posterolateral thoracotomy

Figure 7. Typical thoracic surgery incisions

Boerhaave's syndrome: transmural esophageal perforation
Mallory-Weiss tear: non-transmural esophageal tear (partial thickness tear)
Both are associated with forceful emesis

Standard of Care in 2019
1. Pre and postoperative FLOT chemotherapy for gastric and GE junction adenocarcinoma (docetaxel, oxaliplatin, and fluorouracil/leucovorin)
2. Neoadjuvant CROSS chemoradiotherapy for esophageal cancer with squamous histology or mid-body adenocarcinoma (carboplatin and paclitaxel plus radiotherapy)

6Ss of SCC
Smoking
Spirits (alcohol)
Seeds (betel nut)
Scalding (hot liquid)
Strictures
Sack (diverticula)

Hiatus Hernia

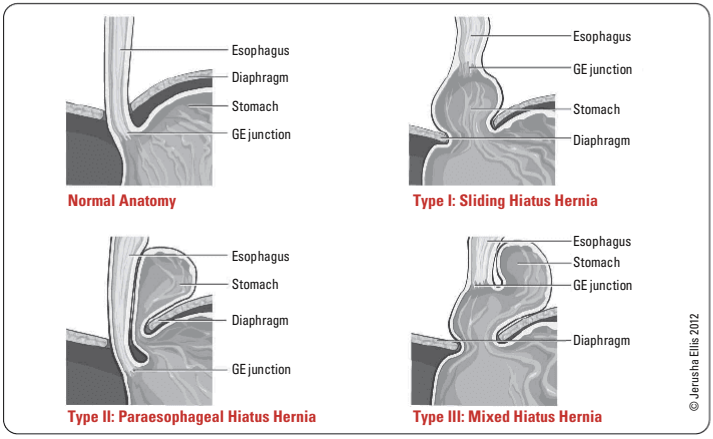


Figure 8. Types of hiatus hernia: Type I: Sliding (GE junction above the level of the diaphragm) Type II: Paraesophageal (GE junction below the diaphragm, fundus rolls past it) Type III: Mixed and Type IV: Massive (not shown) (containing another intra-abdominal organ: bowel/spleen/etc.)

SLIDING HIATUS HERNIA (TYPE I)

- reducible and/or limited herniation of both the stomach and the gastroesophageal (GE) junction into thorax
- 90% of esophageal hernias

Risk Factors

- age
- increased intra-abdominal pressure (e.g. obesity, pregnancy, coughing, and heavy lifting)
- smoking

Clinical Features

- majority are asymptomatic
- symptoms in decreasing frequency are heartburn, regurgitation, eructation, sour taste, and cough

Complications

- complications are due to acid reflux when clinically significant and include these three categories:
  - esophagitis (dysphagia and heartburn)
  - consequences of esophagitis (peptic stricture, Barrett's esophagus, and esophageal carcinoma)
  - extra-esophageal complications (aspiration pneumonitis/pneumonia, bronchospasm, cough, and laryngitis)

Investigations

- barium study
- CXR or CT scan
- 24 h esophageal pH monitoring to quantify reflux and esophageal manometry (technique for measuring LES pressure)
- endoscopy with biopsy to document type and extent of tissue damage and rule out esophagitis, Barrett's esophagus, and cancer

Treatment

- lifestyle modification
  - smoking cessation, weight loss, elevate head of bed, no meals <3 h prior to sleeping, smaller and more frequent meals, avoid alcohol, coffee, mint, chocolate, and fatty foods
- medical
  - PPI, antacid, H2-antagonist, prokinetic agent
- surgical (<15% of cases)
  - consider if: volume regurgitation, patient unwilling or unable to stay on PPI indefinitely, suboptimal medical therapy, complications of GERD such as pharyngitis, esophageal stricture, recurrent nocturnal aspiration, Barrett's esophagus, patient preference
  - laparoscopic hiatus hernia repair and fundoplication
    - fundus of stomach is wrapped around the gastroesophageal junction and sutured in place

- operative principles are reduction of hernia, removal of hernia sac, fundoplication, and partial closure of hiatus
- 360 degree wrap: Nissen Fundoplication (most commonly performed). Dor, and Toupet are partial fundoplications
- expect transient postoperative clinical changes: dysphagia, bloating, excessive gas
- long-term complications may include post-prandial diarrhea and hernia recurrence in minority of patients
- dysphagia and gas bloat may be less with partial fundoplications (Toupet/Dor), however accompanied with higher risk of mild reflux symptoms
- 90% success rate for alleviating GERD

WebSurg
https://websurg.com/en/
WebSurg is an excellent resource which allows trainees to learn many different surgical techniques via videos and lectures. This resource primarily focuses on laparoscopic surgeries

PARAESOPHAGEAL HIATUS HERNIA (TYPE II)
- least common esophageal hernia (<10%)
- herniation of all or part of the stomach through the esophageal hiatus into the thorax with an undisplaced GE junction

Clinical Features
- usually asymptomatic due to normal GE junction
- dysphagia (most common), chest pain, and pressure sensation in lower chest

Complications
- hemorrhage, incarceration, strangulation (gastric volvulus), obstruction, gastric stasis ulcer (Cameron's lesion – causes Fe-deficiency anemia)

Elective laparoscopic procedures for paraesophageal hiatal hernia repair are associated with relatively low mortality. However, this value increases greatly with emergency repairs (7.5% vs. 0.5%)

MIXED HIATUS HERNIA (TYPE III)
- most common indication for surgical repair
- second most common type of hernia – combination of types I and II
- includes giant hernias or intrathoracic stomach
- rare incidence of gastric volvulus (Borschadt's Triad: chest pain, retching, inability to pass NG tube)
- may present with long-standing Fe-deficiency anemia of unknown etiology

Clinical Features
- symptoms may include reflux or heartburn
- most common symptoms: abnormal postprandial fullness after normal-sized meal, chest pain or retrosternal discomfort (gastric angina), and bloating
- can present with gastric outlet obstruction or gastric necrosis secondary to strangulation in the setting of gastric volvulus

Treatment
- surgery to address symptoms or treat/prevent complications
- reduce hernia and excise hernia sac, repair defect at hiatus, and anti-reflux procedure (e.g. Nissen fundoplication)
- may consider suturing stomach to anterior abdominal wall (gastropexy) to reduce the risk of gastric reherniation
- in very elderly patients at high surgical risk consider reduction of hernia and PEG (percutaneous endoscopic gastrostomy) insertion to anchor the stomach in the abdomen

TYPE IV HERNIA
- herniation of stomach and other abdominal organs into thorax: colon, spleen, pancreas, and small bowel
- similar presentation as type III hernia and may include intermittent large bowel symptoms (pain, hematochezia, constipation, etc.) if it is herniated

Achalasia

- esophageal smooth muscle motility disorder which occurs because the lower esophageal sphincter fails to relax
- esophagus does not have peristalsis
- in 50% of patients, the lower esophageal tone is hypertensive resulting in obstruction at the GE junction

Risk Factors
- spinal cord injury

Clinical Features
- dysphagia, initially solid than to liquids though a majority of patients will initially present with dysphagia to both solids and liquids
- regurgitation
- late symptoms include chest pain, nocturnal cough, and weight loss from difficulty eating

Investigations
- barium esophagram with a classic finding of smooth tapering of the lower esophagus to a "bird's beak" appearance
- upper endoscopy
- esophageal manometry will show incomplete lower esophageal sphincter relaxation in response to swallowing and sometimes a lack of peristalsis in the lower esophagus

Treatment
- non-surgical treatment:
  - pharmacologic: nitrates, calcium channel blockers, and phosphodiesterase-5 inhibitors to reduce LES pressure
  - endoscopic botulinum toxin injection
  - pneumatic dilation
- surgical treatment options:
  - laparoscopic Heller myotomy
  - peroral endoscopic myotomy

Complications
- esophageal perforation
- GERD
- bloating

Stomach and Duodenum

Peptic Ulcer Disease

GASTRIC ULCERS
- see Gastroenterology, G11

Indications for Surgery
- treat complications: bleeding (common indication for emergency management), perforation and obstruction (3x greater risk compared to duodenal ulcers)
- refractory to medical management–time period is unclear but generally after 8-12 wk of medical therapy
- suspicion of malignancy (even if biopsy is benign), especially if ulcer fails to heal after 12 wk of medical therapy
- surgery is becoming increasingly rare due to H. pylori eradication, medical treatment, endoscopic treatments (injection therapy with adrenaline, polidocanol, or fibrin glue) and coagulation therapy (heater probe or argon plasma)

Procedures
- ligation of bleeding vessels
- distal gastrectomy with ulcer excision: Billroth II, Roux-en-Y gastrojejunostomy, or Billroth I (rarely) reconstruction
- vagotomy and pyloroplasty only if acid hypersecretion (very rare)
- wedge resection if possible
- biopsy for suspicion of malignancy, followed by gastroscopy to minimize further bleeding and aid with healing

DUODENAL ULCERS
- see Gastroenterology, *Peptic Ulcer Disease, G11*
- most within 2 cm of pylorus (duodenal bulb)

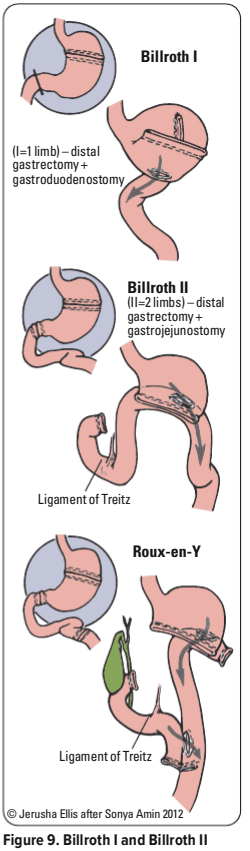
Indications for Surgery
- hemorrhage, rebleed in hospital, perforation, gastric outlet obstruction
- refractory to medical and endoscopic management

Procedures
- omental (Graham) patch: plication of perforated ulcer supported by overlying omental patch
- oversewing of bleeding ulcer ± pyloroplasty
- treat with *H. pylori* eradication protocol postoperatively

Complications of Gastric Surgery
- retained antrum
- fistula (gastrocolic/gastrojejunal)
- dumping syndrome, postvagotomy diarrhea, afferent loop syndrome

Table 12. Complications of Duodenal Ulceration

Complication	Clinical Features	Management
Perforated Ulcer (typically on anterior surface)	Sudden onset of pain (possibly in RLQ due to track down right paracolic gutter) Acute abdomen: rigid, diffuse guarding Ileus Initial chemical peritonitis followed by bacterial peritonitis	Investigation CXR free air under diaphragm (70% of patients) Treatment Oversew ulcer (plication) and omental (Graham) patch most common treatment
Penetration to Nearby Organs	Elevated amylase/lipase if penetration into pancreas Elevated hepatic transaminases if penetration into liver (rare, but serious) Constant mid-epigastric pain burrowing into back, unrelated to meals	Management should follow the intensive measures for refractory ulcers
Hemorrhage (typically on posterior surface)	Gastroduodenal artery involvement	Resuscitation initially with crystalloids; blood transfusion if necessary Diagnostic and/or therapeutic endoscopy (laser, cautery, or injection); if recurs, may have second scope Consider interventional radiology: angiography with embolization/coiling Surgery if severe or recurrent bleeding, hemodynamically unstable, or failure of endoscopy and IR: oversewing of ulcer, pyloroplasty
Gastric Outlet Obstruction	Ulcer can lead to edema, fibrosis of pyloric channel, and neoplasm N/V (undigested food, non-bilious), dilated stomach, and crampy abdominal pain Succussion splash (splashing noise heard with stethoscope over the stomach when patient is shaken) Auscultate gas and fluid movement in obstructed organ	NG tube decompression and correction of hypochloremic, hypokalemic metabolic alkalosis Medical management initially: high-dose PPI therapy Surgical resection if obstruction does not resolve: either Billroth I, pyloroplasty, or gastrojejunostomy



Billroth I
(I=1 limb) – distal gastrectomy + gastroduodenostomy
Billroth II
(II=2 limbs) – distal gastrectomy + gastrojejunostomy
Ligament of Treitz
Roux-en-Y
Ligament of Treitz

Figure 9. Billroth I and Billroth II with Roux-en-Y reconstruction (gastrojejunostomy)

Gastric Carcinoma

Epidemiology

- 5th most common cancer in the world
- M:F=3:2
- most common age group = 50-59 yr
- incidence has decreased by 2/3 in past 50 yr
- incidence highest in Asian, Latin American, and Caribbean countries

Risk Factors

- compensatory epithelial cell proliferation via gastric atrophy from:
  - *H. pylori*, causing chronic atrophic gastritis
  - pernicious anemia associated with achlorhydria and chronic atrophic gastritis
  - previous partial gastrectomy (>10 yr post-gastrectomy)
- lifestyle and environmental factors:
  - salt and salt-preserved food (e.g. salted fish, cured meat, and salted vegetables)
  - obesity
  - cigarette smoking
  - EBV infection
  - abdominal radiation therapy
- host-related factors
  - blood type A – also associated with pernicious anemia
  - hereditary nonpolyposis colorectal cancer (HNPCC), hereditary diffuse gastric carcinoma (HDGC)
  - gastric adenomatous polyps
  - hypertrophic gastropathy
  - genetic syndromes: hereditary diffuse gastric cancer (e.g. E-cadherin (CDH1)) gene

Clinical Features

- clinical suspicion
  - ulcer fails to heal
  - lesion on greater curvature of stomach or cardia
- asymptomatic, insidious, or late onset of symptoms
  - postprandial abdominal fullness, pseudoachalasia (in older patients), vague epigastric pain
  - anorexia or weight loss
  - eructation, N/V, dyspepsia, and dysphagia
  - hepatomegaly, epigastric mass (25%)
  - hematemesis, fecal occult blood, melena, and iron-deficiency anemia
- metastasis
  - peritoneum, ovarian, liver, lung, and brain

Investigations

- OGD and biopsy; consider EUS to assess preoperative T-stage and N-stage
- CT chest/abdomen/pelvis (with gastric protocol)

Kissing Ulcer: combination of perforation and bleeding

Signs of Metastatic Gastric Carcinoma
Virchow's Node: left supraclavicular node
Blumer's Shelf: mass in pouch of Douglas
Krukenberg Tumour: metastases to ovary
Sister Mary Joseph Node: umbilical metastases
Irish's Node: left axillary nodes

Table 13. TNM Classification System for Staging of Gastric Carcinoma (AJCC/IUCC 2017, 8th edition)

Primary Tumour (T)		Regional Lymph Nodes (N)		Distant Metastasis (M)	
TX	Primary tumour cannot be assessed	**NX**	Cannot be assessed	**M0**	No distant metastasis
T0	No evidence of primary tumour	**N0**	No regional node metastasis	**M1**	Distant metastasis
Tis	Carcinoma *in situ*	**N1**	Metastasis in 1-2 regional nodes		
T1a	Invasion into lamina propria or muscularis mucosae	**N2**	Metastasis in 3-6 regional nodes		
T1b	Invasion into submucosa	**N3a**	Metastasis in 7-15 regional nodes		
T2	Invasion into muscularis propria	**N3b**	Metastasis in ≥16 regional nodes		
T3	Penetration of subserosal connective tissue without tissue invasion of visceral peritoneum or adjacent structures				
T4a	Invasion into serosa				
T4b	Invasion into adjacent structures				

Treatment

- adenocarcinoma
  - proximal lesions
    - total gastrectomy and Roux-en-Y esophagojejunostomy
  - distal lesions
    - subtotal gastrectomy: wide margins, en bloc removal of omentum and lymph nodes (D2 lymphadenectomy) with Roux-en-Y or Billroth II reconstruction
  - adjuvant therapies
    - perioperative chemotherapy or postoperative chemoradiotherapy in addition to surgery is standard of care in a curative intent strategy
  - palliation
    - limited gastric resection or endoscopic stenting to decrease bleeding and relieve obstruction, enables the patient to eat
    - radiation therapy
    - studies are showing larger role for palliative chemotherapy
- lymphoma
  - *H. pylori* eradication, chemotherapy ± radiation, and surgery in limited cases (perforation, bleeding, and obstruction)

Staging and 5 Yr Survival Rates for Gastric Cancer

Stage	TNM	5 Yr Survival
IA	T1N0M0	71%
IB	T2N0M0	57%
	T1N1M0	
IIA	T3N0M0	45%
	T2N1M0	
	T1T2M0	
IIB	T4aN0M0	33%
	T3N1M0	
	T2N2M0	
	T1N3M0	
IIIA	T4aN1M0	20%
	T3T2M0	
	T2N3M0	
IIIB	T4bN0M0	14%
	T4bN1M0	
	T4aN2M0	
	T3N3M0	
IIIC	T4bN2M0	9%
	T4bN3M0	
	T4aN3M0	
IV	TxNxM1	4%

Gastrointestinal Stromal Tumour

Epidemiology

- most common mesenchymal neoplasm of GI tract
- derived from interstitial cells of Cajal (cells associated with Auerbach's plexus that have autonomous pacemaker function which coordinate peristalsis throughout the GI tract)
- 75-80% associated with tyrosine kinase (c-KIT) mutations
- most common in stomach (50%) and proximal small intestine (25%), but can occur anywhere along GI tract
- often discovered incidentally on CT, laparotomy, or endoscopy

Neoadjuvant Chemotherapy in Advanced Gastric and Esophago-Gastric Cancer. Meta-Analysis of Randomized Trials
Int J Surg 2018;51:120-127
Study: Meta-analysis evaluating the effects of neoadjuvant chemotherapy on advanced gastric cancer.
Results/Conclusions: Neoadjuvant chemotherapy and resection reduces overall mortality at 3 and 5 yr in advanced gastric cancer (RR=0.74; 0.82 respectively). Morbidity and perioperative mortality rate are not influenced by NACT. Recurrence rate is reduced by NACT + surgery in EGC (RR=0.80).

Risk Factors

- Carney triad: gastric GISTs, extra-adrenal paraganglioma, and pulmonary chondroma
- type I neurofibromatosis
- Carney-Stratakis syndrome

Clinical Features

- most commonly in stomach (40-60%) and jejunum (25-30%)
- typically present with vague abdominal mass, feeling of abdominal fullness, or with secondary symptoms of bleeding and anemia
- sometimes asymptomatic (13-18%)
- nonspecific symptoms (8-17%): bloating, early satiety, abdominal pain/discomfort
- overt or occult GI bleeding (50% of gastric GISTs)

Investigations

- contrast-enhanced CT is preferred imaging for screening and staging; MRI if IV contrast not feasible
- preoperative biopsy (EUS): useful for indeterminate lesions (not recommended if high index of suspicion for GIST)
- given that lesions are submucosal, mucosal biopsies are sometimes non-diagnostil

Treatment
- surgical resection if >2 cm; follow with serial endoscopy if <2 cm (gastric GIST) and resect if growing or symptomatic
- localized GIST
  - surgical resection with preservation of intact pseudocapsule
  - lymphadenectomy NOT required as GISTs rarely metastasize to lymph nodes
  - consider adjuvant treatment with imatinib (Gleevec®) if high-risk of relapse (large, >4 cm with significant mitotic activity)
- advanced disease (i.e. metastases to liver and/or peritoneal cavity)
  - palliative intent chemotherapy with imatinib
  - metastasectomy may be considered for liver limited disease

Prognosis
- risk of metastatic potential depends on
  - tumour size (worse if >10 cm)
  - mitotic activity (worse if >5 mitotic figures/50 HPF)
  - degree of nuclear pleomorphism
  - location: with identical sizes, extra-gastric location has a higher risk of progression than GISTs in the stomach
- frequently metastasize to the liver and omentum; nodal and lung metastases rare

Extent of Lymph Node Dissection for Adenocarcinoma of the Stomach
Cochrane DB Syst Rev 2015;12:CD001964
Study: Systematic review and meta-analysis on the evidence that existed regarding the impact of the three main types of progressively more extended lymph node dissection (that is, D1, D2 and D3 lymphadenectomy) on the clinical outcome of patients with primary resectable carcinoma of the stomach.
Results/Conclusions: Data suggested no significant difference in overall survival between D2 and D3 type dissection. There was no significant difference in overall survival between D1 and D2 type node dissection. In contrast, D2 lymphadenectomy was associated with a significantly better disease specific survival compared to D1 lymphadenectomy but was also associated with a higher postoperative mortality rate.

Bariatric Surgery

- weight reduction surgery for morbid obesity
- indications: BMI ≥35 without illness or BMI ≥30 with 1+ serious comorbidity (e.g. DM, CAD, sleep apnea, GERD, or severe joint disease)
  - Asian patients: growing evidence to lower BMI criteria by 2.5 (i.e. BMI ≥37.5 or BMI ≥35.5) due to higher prevalence of truncal obesity
- consult with a multidisciplinary bariatric team: nutrition, psychological deterrents, life modifications, lifelong surveillance, reliable bariatric program (details realistic outcomes) to optimize success post-operation

Surgery for Weight Loss in Adults
Cochrane DB Syst Rev 2014;8:CD003641
Study: Update of a 2003 Cochrane review assessing the effects of bariatric surgery and control of comorbidities.
Conclusions: Surgery resulted in decreased BMI one to two years postoperative. 3 RCTs found that laparoscopic Roux-en-Y gastric bypass achieved significantly greater weight loss and BMI reduction up to 5 yr after surgery compared with laparoscopic adjustable gastric banding (mean difference -5.2 kg/m^2; 95% CI -6.4 to -4.0). More patients experienced remission of diabetes with lap R-en-Y, however, different definitions were used. Risks of surgery include leaks, hernias, infection, pulmonary embolism, cholecystitis, and postoperative mortality.

Surgical Options
- combination malabsorptive and restrictive
  - laparoscopic Roux-en-Y gastric bypass (most common, most effective; higher complication rates)
    - small gastric pouch (restrictive), from distal stomach, anastomosed with Roux limb of small bowel (malabsorptive); connect to biliopancreatic limb to maintain digestive enzymes and bile
    - complications: gastric remnant distention, stomal stenosis, marginal ulcers, cholelithiasis, ventral incisional hernia, short bowel syndrome, dumping syndrome, metabolic perturbations, gastrogastric fistula
  - restrictive laparoscopic sleeve gastrectomy
    - creation of tubular stomach via removal of majority of greater curvature
    - complications: bleeding from gastric or short gastric vessels from dissection of greater curve, stenosis at the gastroesophageal junction, gastric leaks
- malabsorptive
  - biliopancreatic diversion with duodenal switch (performed as a rescue operation after traditional Roux-en-y)
    - anastomosis of stomach to distal ileum, anastomosis of biliopancreatic limb to terminal Ileum
    - complications: protein calorie malnutrition, anemia, metabolic bone disease, fat-soluble vitamin deficiency

Complications of Gastric Surgery
- most resolve within 1 yr
- important to note that morbidly obese patients usually do not present with the symptoms and signs shown below; often times, the only presenting sign is tachycardia

Alkaline Reflux Gastritis
- duodenal contents (bilious) reflux into stomach causing gastritis ± esophagitis
- treatment
  - medical: H2-blocker, metoclopramide, cholestyramine (bile acid sequestrant)
  - surgical: conversion of Billroth I or II to Roux-en-Y

Afferent Loop Syndrome
- accumulation of bile and pancreatic secretions causes intermittent mechanical obstruction and distention of afferent limb
- clinical features
  - early postprandial distention, RUQ pain, nausea, bilious vomiting, anemia
- treatment: surgery (conversion to Roux-en-Y increases afferent loop drainage)

Dumping Syndrome
- early: 15-30 min postprandial
  - etiology
    - rapid emptying of hyperosmotic chyme leads to jejunal distention, stimulating release of vasoactive hormones
  - clinical features
    - postprandial epigastric cramping, bloating, emesis, nausea, and vasomotor symptoms (dizziness, palpitations, tachycardia, diaphoresis)
  - treatment
    - frequent small meals high in fibre and protein, low in carbohydrates; avoidance of liquids with meals
    - last resort is interposition of antiperistaltic jejunal loop between stomach and small bowel to delay gastric emptying
- late: 3 h postprandial
  - etiology: hypoglycemia following postprandial insulin peak
  - treatment: small snack 2 h after meals

Blind-Loop Syndrome
- bacterial overgrowth of colonic Gram-negative bacteria in afferent limb
- clinical features
  - anemia/weakness, diarrhea, malnutrition, abdominal pain, and hypocalcemia
- treatment: broad-spectrum antibiotics and surgery (conversion to Billroth I)

Postvagotomy Diarrhea
- up to 25%
- bile salts in colon inhibit water resorption
- treatment: medical (cholestyramine) and surgical (reversed interposition jejunal segment)

SMALL INTESTINE

Small Bowel Obstruction

Mechanical Small Bowel Obstruction

Pathophysiology
- obstruction → gas and fluid (swallowed or GI secretions) accumulate proximal to site of obstruction and distal decompression → intestinal activity increases to overcome obstruction → colicky pain and diarrhea (initially)

Etiology

Table 14. Common Causes of SBO

Intraluminal Foreign Body	Intramural	Extramural (>85% of causes)
Intussusception Gallstones (gallstone ileus) Bezoars Foreign body	Crohn's Radiation stricture Neoplasm (adenocarcinoma, carcinoid, lymphoma, sarcoma)	Adhesions from previous surgeries (75% SBO) Incarcerated hernia Peritoneal carcinomatosis

- AAST grading system for severity (Grade - "Operative Criteria")
  - partial SBO - minimal intestinal distension with no evidence of obstruction
  - complete SBO with viable bowel - intestinal distension with transition point: no bowel compromise
  - complete SBO with compromised but viable bowel - intestinal distension with impending bowel compromise
  - complete SBO with nonviable bowel or perforation and localized spillage - intestinal distension with localized perforation or free fluid
  - small bowel perforation with diffuse peritoneal contamination - intestinal distension with perforation, free fluid, and diffuse peritonitis
- closed-loop obstruction is when a segment is obstructed in two separate locations, creating a segment with no proximal or distal outlet and can rapidly progress to complications and require immediate abdominal exploration

Risk Factors
- prior abdominal or pelvic surgery (adhesions)
- abdominal wall or groin hernia
- personal history or increased risk of malignancy
- prior radiation

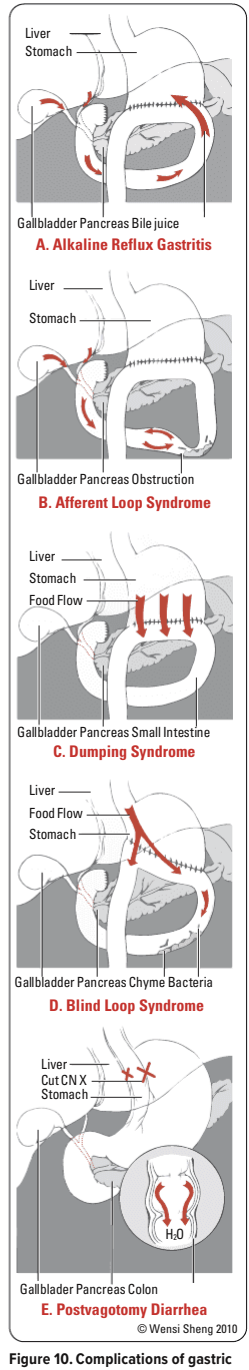

Figure 10. Complications of gastric surgery

- IBD
- history of foreign body ingestion

Clinical Features
- symptoms: colicky periumbilical abdominal pain, N/V, obstipation, delayed passage/inability to pass flatus, inability to tolerate an oral diet
  - more feculent vomitus suggests more established obstruction because of bacterial overgrowth
  - passage of gas and/or stool that continues 6-12 h after onset of symptoms suggests partial rather than complete obstruction
  - inability to pass flatus is the most useful indicator
- signs: abdominal distention (most prominent if obstruction at distal ileum), hyperactive proceeding to minimal bowel sounds, bloating, hypovolemia, hyperresonance with percussion
- strangulated obstruction: abdominal pain disproportionate to physical exam findings suggest intestinal ischemia
  - may have tachycardia, localized abdominal tenderness, fever, marked leukocytosis, and lactic acidosis

Investigations
- approach
  1. distinguish mechanical obstruction from ileus
  2. determine likely and easily reversible etiology of obstruction
  3. differentiate complicated (e.g. strangulated) obstruction
- imaging
  - usually if you suspect a bowel obstruction, a CT scan is the first line. Further, once CT scan confirms a bowel obstruction,, we perform 6 and 12 hour X-rays after giving water soluble contrast which is diagnostic for obstruction and often therapeutic
  - CT with IV contrast: discrete transition zone/point with proximal bowel dilation, distal bowel decompression, and intraluminal contrast does not pass the transition zone
    - most importantly to rule out ischemic bowel/strangulation: pneumatosis intestinalis (free air in bowel wall) and thickened bowel wall, air in portal vein, free intraperitoneal fluid, and differential wall enhancements (poor uptake of IV contrast into the wall of the affected bowel)
  - other (less common)
    - upper GI series/small bowel series (if no cause apparent, i.e. no hernias, and no previous surgeries)
    - serial CTs with oral contrast
    - may consider U/S or MRI in pregnant patients
- laboratory
  - may be normal early in disease course
  - CBC, electrolytes, BUN, creatinine, lactate
  - creatinine and hematocrit to assess degree of dehydration
  - may have fluid and electrolyte abnormalities with metabolic alkalosis due to frequent emesis
  - if strangulation: leukocytosis with left shift, elevated lactate (late signs)

Treatment
- IV isotonic fluid resuscitation and urine output monitoring with catheter
  - SBO related vomiting and decreased PO intake leads to volume depletion
- NG tube in the stomach for gastric decompression; decrease nausea, distention, and risk of aspiration from vomiting
- NPO
- if partial SBO/Crohn's/Carcinomatosis: conservative management with fluid resuscitation and NG tube decompression
  - 48 h of watchful waiting; if no improvement or develops complications, surgery
  - for Crohn's patients, consider GI consult for steroid management
- if no clinical features of ischemia: short course of conservative management with fluid resuscitation and NG tube decompression with frequent re-examination by surgical team
  - duration of observation varies from hours to a few days
  - if SBO fails to resolve, or if symptoms of ischemia develop, then surgery
- if high-risk for ischemia based on clinical symptoms: urgent surgery to prevent irreversible ischemia
  - early postoperative SBO: if bowel function does not return within 3-5 d after surgery; usually partial, extended conservative therapy (2-3 wk) with bowel rest, fluids, and TPN is appropriate
- immediate surgery if ischemia, necrosis, and perforation
  - clinical signs: fever, leukocytosis, tachycardia, worsening pain, metabolic and lactic acidosis, and tachypnea
  - radiologic signs: free air on radiographs or CT, closed-loop obstruction, abnormal course of a mesenteric vessel, and high-density free fluid

Prognosis
- related to etiology; mortality: non-strangulating <1%, strangulating 8% (25% if >36 h), ischemic = up to 50%
- surgical intervention associated with a lower risk of recurrence

Prevention
- open surgery has four-fold increase in risk of SBO in 5 yr compared to laparoscopic surgery

Increased Risk of Perforation with Distention as seen on Abdomen Imaging
Small bowel ≥3 cm
Distal colon ≥6 cm
Proximal colon ≥9 cm
Cecum ≥12 cm

Important to know if chronic vs. acute. Chronic distention is more likely to be tolerated without perforation

Patients with NO Abdominal Surgery History ("Virgin Abdomen")
Presenting with a SBO should have surgery ASAP (EXCEPTION: malignant obstruction from history and imaging)

Patients with Abdominal Surgery History ("Non-virgin Abdomen")
Adhesional SBOs resolve spontaneously with NG tube decompression 70% of time

Top 3 Causes of SBO (in order)

ABC
Adhesions
Bulge (hernias)
Cancer (neoplasms)

Causes of SBO

SHAVING
Stricture
Hernia
Adhesions
Volvulus
Intussusception/IBD
Neoplasm
Gallstones

Paralytic Ileus

Pathogenesis
- temporary, reversible impairment of intestinal motility; most frequently caused by:
  - abdominal operations, infections and inflammation, medications (opiates, anesthetics, psychotropics), and electrolyte abnormalities
  - often seen for patients in the postoperative setting from intra-abdominal sepsis (perforated appendicitis, diverticulitis, etc.)
  - pathophysiology related to inhibitory splanchnic reflexes, inhibitory sympathetic activity, inflammatory stress response, peptides (VIP, substance P, Calcitonin gene-related peptide (CGRP))
- NOT the same as intestinal pseudo-obstruction
  - chronic pseudo-obstruction refers to specific disorders that affect the smooth muscle and myenteric plexus, leading to irreversible intestinal dysmotility

Clinical Features
- symptoms and signs of intestinal obstruction without mechanical obstruction
  - bowel sounds are diminished or absent (in contrast to initial hyperactive bowel sounds in SBO)
  - pain is often diffuse and less frequently has the colicky pattern present in mechanical obstruction
  - passing gas is the most useful indicator
- postoperative: gastric and small bowel motility returns by 24-48 h, colonic motility by 3-5 d

Investigations
- routine postoperative ileus: expected, no investigation needed
- if ileus persists or occurs without abdominal surgery
  - review patient medications (especially opiates)
  - measure serum electrolyte to monitor for electrolyte abnormalities (including extended electrolytes like Mg^{2+}, Ca^{2+}, PO_4^{3-})
  - creatinine and BUN
  - LFTs
  - CT scan to rule out abscess or peritoneal sepsis, or to exclude mechanical obstruction

Treatment
- address underlying cause
- most important initial treatment: NPO + fluid resuscitation
- for prolonged ileus: NG tube decompression, TPN, and pain management

Intestinal Ischemia

Etiology
- acute
  - arterio-occlusive mesenteric ischemia (AOMI)
    - thrombotic, embolic, and extrinsic compression (e.g. strangulating hernia)
  - non-occlusive mesenteric ischemia (NOMI)
    - mesenteric vasoconstriction secondary to systemic hypoperfusion (preserves supply to vital organs)
  - mesenteric venous thrombosis (MVT)
    - consider hypercoagulable state (i.e. rule out malignancy) and DVT (prevents venous outflow)
- chronic: usually due to atherosclerotic disease – look for cardiovascular risk factors
- can lead to occlusion in vessels that supplies the small intestine and the large intestine

Pain "out of keeping with physical findings" is the hallmark of early intestinal ischemia

Clinical Features
- acute: severe abdominal pain out of proportion to physical findings, vomiting, bloody diarrhea, bloating, minimal peritoneal signs early in course, hypotension, shock, and sepsis
- chronic: postprandial pain (from mesenteric angina), fear of eating, and weight loss
- common sites: SMA supplied territory, "watershed" areas of colon – splenic flexure, left colon, and sigmoid colon

Investigations
- laboratory: leukocytosis (non-specific) and lactic acidosis (late finding)
  - lactate used to observe progress
  - hypercoagulability workup if suspect venous thrombosis
- AXR: portal venous gas, intestinal pneumatosis, and free air if perforation
- contrast CT: thickened bowel wall, luminal dilatation, SMA or SMV thrombus, mesenteric/portal venous gas, and pneumatosis
- CT angiography is the gold standard for acute arterial ischemia

An acute abdomen + metabolic acidosis is bowel ischemia until proven otherwise

Treatment
- fluid resuscitation, correct metabolic acidosis, NPO, NG tube decompression of stomach, and prophylactic broad-spectrum antibiotics; avoid vasoconstrictors and digitalis
- exploratory laparotomy/laparoscopy to assess extent of viability ± segmental resection of necrotic intestine
  - if extent of bowel viability is uncertain, a second-look laparotomy 12-24 h later is mandatory
- angiogram, embolectomy/thrombectomy, bypass/graft, mesenteric endarterectomy, anticoagulation therapy, and percutaneous transluminal angioplasty ± stent

Tumours of Small Intestine

BENIGN TUMOURS

- 10x more common than malignant
- usually asymptomatic until large
- most common sites: terminal ileum and proximal jejunum
- polyps
  - adenomas
  - hamartomas
  - FAP (see *Familial Colon Cancer Syndromes, GS42*)
  - juvenile polyps
- other: leiomyomas, lipomas, and hemangiomas

Table 15. Malignant Tumours of the Small Intestine

	Adenocarcinoma	Carcinoid/GI NET-Neuroendocrine Tumour	Lymphoma	Metastatic
Epidemiology	Usually 50-70 yr M>F	Increased incidence 50-60 yr	Highest incidence in 70s M>F Usually non-Hodgkin's lymphoma	Most common site of GI metastases in patients with metastatic melanoma
Risk Factors	Crohn's, FAP, history of CRC, HNPCC		Crohn's, celiac disease, autoimmune disease, immunosuppression, radiation therapy, and nodular lymphoid hyperplasia	Melanoma, breast, lung, ovary, colon, and cervical cancer
Origin/Location	Usually in proximal small bowel, incidence decreases distally	Classified based on embryological origin (foregut, midgut, and hindgut) Originate from gut enterochromaffin cell Appendix 46%, distal ileum 28%, rectum 17%	Usually distal ileum Proximal jejunum in patients with celiac disease	Hematogenous spread from breast, lung, and kidney Direct extension from cervix, ovaries, and colon
Clinical Features	Early metastasis to lymph nodes 80% metastatic at time of operation Abdominal pain (common)	N/V, anemia, GI bleeding, jaundice, and weight loss (less common) Often slow-growing Usually asymptomatic, incidental finding Obstruction, bleeding, crampy abdominal pain, and intussusception Carcinoid syndrome (<10%) Hot flashes, hypotension, diarrhea, bronchoconstriction, and right heart failure Requires liver involvement: lesion secretes serotonin, kinins, and vasoactive peptides directly to systemic circulation (normally inactivated by liver)	Fatigue, weight loss, fever malabsorption, abdominal pain, anorexia, vomiting, constipation, and mass Rarely perforation, obstruction, bleeding, and intussusception	Obstruction and bleeding
Investigations	CT abdomen/pelvis Endoscopy	Most found incidentally at surgery for obstruction or appendectomy CT thorax/abdomen/pelvis Consider small bowel enteroclysis to look for primary Serum chromogranin A as a tumour marker Elevated 5-HIAA (breakdown product of serotonin) in urine or increased 5-HT in blood Some nuclear medicine testing available but should be done by endocrine oncologist. Testing includes Galium DOTATATE PET scans and octreotide scans	CT abdomen/pelvis	CT abdomen/pelvis
Treatment	Surgical resection ± chemotherapy	Surgical resection ± chemotherapy Carcinoid syndrome treated with octreotide Metastatic risk 2% if size <1 cm, 90% if >2 cm	Low-grade: chemotherapy with cyclophosphamide High-grade: surgical resection, and radiation Palliative: somatostatin, doxorubicin	Palliation
Prognosis	5 yr survival 25% (if node positive)	5 yr survival 70%; 20% with liver metastases Based on the Ki67 index	5 yr survival 40%	Poor
Staging System	TNM	TNM	Ann Arbor	

Carcinoid Syndrome Symptoms

FDR
Flushing
Diarrhea
Right-sided heart failure

Indirect Inguinal Hernias: Rule of 5s

5% lifetime incidence in males
5x more common than direct inguinal hernias
5-10x more common in males than females
Generally occur by **5**th decade of life

Short Gut Syndrome

Definition
- reduced surface area (length) of small bowel causing insufficient intestinal absorption leading to diarrhea, malnutrition, and dehydration

Etiology
- due to surgical resection
  - large amount of bowel at once (acute mesenteric ischemia, trauma, malignancies)
  - cumulative resections (Crohn's disease)
- in infant and pediatric patients, the most common causes are necrotizing enterocolitis, abdominal wall defects, jejunal ileal atresia, and midgut volvulus

Prognostic Factors
- residual small bowel length, residual colon length (reabsorption of water and electrolytes and some reabsorption of nutrients), condition of the remnant small bowel (healthier bowel facilitate better reabsorption), presence of ileocecal valve (delay transition into colon leading to more reabsorption)
- resection of ileum is less tolerated than resection of jejunum (ileum reabsorbs bile salt and vitamin B_{12})

Therapy
- medical
  - IV fluids in acute management (initial 3-4 wk following resection) and TPN once stabilized to replenish lost fluid and electrolytes in diarrhea
  - histamine 2-receptor antagonist or PPI to prevent gastric acid secretion
  - antimotility agent to prolong transit time in the small intestine
  - consider octreotide to decrease GI secretion and cholestyramine for bile acid absorption
- surgical: non-transplant
  - to slow transit time: small bowel segmental reversal, intestinal valve construction, or electrical pacing of small bowel
  - to increase intestinal length:
    - LILT (longitudinal intestinal lengthening and tailoring) procedure
    - STEP (serial transverse enteroplasty procedure) in dilated small bowels
- surgical: small bowel transplant
  - indication: life-threatening complication from intestinal failure or long-term TPN, including liver failure, thrombosis of major central veins, recurrent catheter-related sepsis, and recurrent severe dehydration

Abdominal Hernia

• see *Hiatus Hernia, GS23*

Definition
- defect in abdominal wall causing abnormal protrusion of intra-abdominal contents

Epidemiology
- M:F=9:1
- lifetime risk of developing a hernia: males 20-25%, females 2%
- frequency of occurrence: 50% indirect inguinal, 25% direct inguinal, 8-10% incisional (ventral), 5% femoral, and 3-8% umbilical
- most common surgical disease in males

Risk Factors
- activities which increase intra-abdominal pressure
  - obesity, chronic cough, asthma, COPD, pregnancy, constipation, bladder outlet obstruction, ascites, and heavy lifting
- congenital abnormality (e.g. patent processus vaginalis and indirect inguinal hernia)
- previous hernia repair, especially if complicated by wound infection
- loss of tissue strength and elasticity (e.g. hiatal hernia, aging, and repetitive stress)
- family history

Clinical Features
- mass of variable size
- tenderness worse at end of day, relieved with supine position or with reduction
- abdominal fullness, vomiting, constipation
- transmits palpable impulse with coughing or straining

Investigations
- physical examination usually sufficient
- U/S ± CT (CT required for obturator hernias, internal abdominal hernias, and Spigelian and/or femoral hernias in obese patients)

Inguinal Hernias

MD's don't LIe
MD: **M**edial to the inferior epigastric a. = **D**irect inguinal hernia
LI: Lateral to the inferior epigastric a. = **I**ndirect inguinal hernia
Inguinal Canal Walls = MALT x 2

2 M Roof	2 muscles (internal oblique, transversus abdominis)
2 A Ant. wall	2 aponeuroses (external and internal oblique)
2 L Floor	2 ligaments (inguinal and lacunar)
2 T Post. wall	2T (transversalis fascia, conjoint tendon)

Borders of Hesselbach's Triangle
- Lateral: inferior epigastric artery
- Inferior: inguinal ligament
- Medial: lateral margin of rectus sheath

Shouldice Technique vs. Other Open Techniques for Inguinal Hernia Repair
Cochrane DB Syst Rev 2012;4:CD001543
Purpose: To evaluate the efficacy and safety of the Shouldice technique compared to other non-laparoscopic techniques.
Results/Conclusions: 16 RCTs or quasi-randomized RCTs with 2566 hernias (1121 mesh; 1608 non-mesh). The recurrence rate with Shouldice was higher than mesh (OR 3.80, 95% CI 1.99-7.26) but lower than non-mesh (OR 0.62, 95% CI 0.45-0.85). There was no difference in chronic pain or complications. In conclusion, with respect to recurrence rates, Shouldice herniorrhaphy is the best non-mesh technique, although inferior to mesh. However, it is also more time consuming and results in slightly longer postoperative hospital stays.

Long-Term Results of a Randomized Controlled Trial of a Nonoperative Strategy (Watchful Waiting) for Men with Minimally Symptomatic Inguinal Hernias
Ann Surg 2013;258:508-514
Purpose: Ascertaining the long-term crossover (CO) rate in patients with asymptomatic or minimally symptomatic inguinal hernias undergoing watchful-waiting (WW) as their primary treatment modality.
Background: A 2006 RCT comparing WW with routine inguinal hernia repair, concluded that WW was an acceptable option in the management of male patients with minimal symptoms (JAMA 2006;295(3):285-292). This study analyzes the WW group after 7 yr of follow-up.
Conclusions: The estimated CO rate for the WW cohort was 68%, while men older than 65 had a rate of 79%. Therefore, while WW is a safe strategy, it is likely that symptoms will progress, and definitive surgical management will be indicated.

Outcomes of Laparoscopic vs. Open Repair of Primary Ventral Hernias
JAMA Surg 2013;148:1043-1048
See Landmark General and Thoracic Surgery Trials table for more information on outcomes of patients electively undergoing laparoscopic ventral hernia repair (LVHR) vs. open ventral hernia repair (OVHR)

Classification
- complete: hernia sac and contents protrude through defect
- incomplete: partial protrusion through the defect
- internal hernia: sac herniating into or involving intra-abdominal structure
- external hernia: sac protrudes completely through abdominal wall
- strangulated hernia: vascular supply of protruded viscus is compromised (ischemia)
  - requires emergency repair
- incarcerated hernia: irreducible hernia, not necessarily strangulated
- Richter's hernia: only part of bowel circumference (usually antimesenteric border) is incarcerated or strangulated so may not be obstructed
  - a strangulated Richter's hernia may self-reduce and thus be overlooked, leaving a gangrenous segment at risk of perforation in the absence of obstructive symptoms
- sliding hernia: part of wall of hernia sac formed by retroperitoneal structure (usually colon)

Anatomical Types
- groin
  - indirect and direct inguinal, femoral
  - pantaloon: combined direct and indirect hernias, peritoneum draped over inferior epigastric vessels
- epigastric: defect in linea alba above umbilicus
- incisional: ventral hernia at site of wound closure, may be secondary to wound infection
- other: Littre's (involving Meckel's), Amyand's (containing appendix), lumbar, obturator, peristomal, umbilical, Spigelian (ventral hernia through linea semilunaris)

Complications
- incarceration
- strangulation
  - small, new hernias more likely to strangulate
  - femoral > indirect inguinal > direct inguinal
  - intense pain followed by tenderness
  - intestinal obstruction, gangrenous bowel, sepsis
  - surgical emergency
  - DO NOT attempt to manually reduce hernia if septic or if contents of hernial sac gangrenous. This will result in reduction of gangrenous contents and subsequent need for laparotomy

Treatment
- surgical treatment (herniorrhaphy) is only to prevent strangulation and evisceration, for symptomatic relief, or for cosmesis; if asymptomatic, can delay surgery. Data has shown that prophylactic surgery does not affect rate of strangulation in ASYMPTOMATIC patients
- repair may be done open or laparoscopic and may use mesh for tension-free closure
- most repairs are now done using tension free techniques – a plug in the hernial defect and a patch over it or patch alone
- observation is acceptable for small asymptomatic inguinal hernias

Postoperative Complications
- recurrence (15-20%)
  - risk factors: recurrent hernia, ages >50, smoking, BMI >25, poor preoperative functional status (ASA ≥3 – see Anesthesia, A4), associated medical conditions: T2DM, hyperlipidemia, immunosuppression, and any comorbid conditions increasing intra-abdominal pressure
  - less common with mesh/"tension-free" repair
- scrotal hematoma (3%)
  - painful scrotal swelling from compromised venous return of testes
  - deep bleeding: may enter retroperitoneal space and not be initially apparent
  - difficulty voiding
- nerve entrapment
  - ilioinguinal (causes numbness of inner thigh or lateral scrotum)
  - genital branch of genitofemoral (in spermatic cord)
- stenosis/occlusion of femoral vein
  - acute leg swelling
- ischemic colitis
- minimally invasive repair for ventral and umbilical hernia

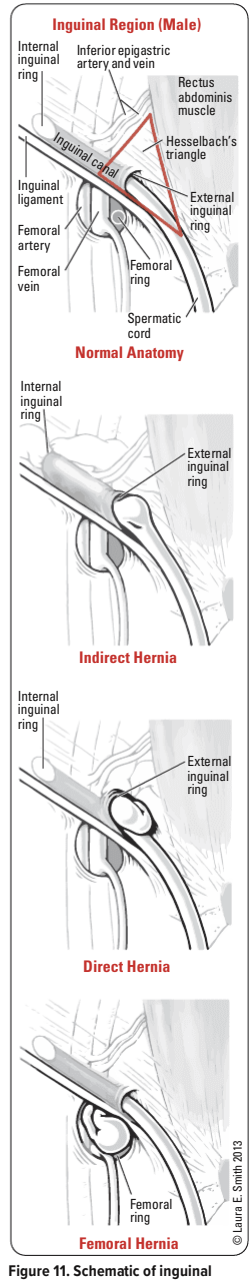

Figure 11. Schematic of inguinal (direct and indirect) and femoral hernias

Groin Hernias

Table 16. Groin Hernias

	Direct Inguinal	Indirect Inguinal	Femoral
Epidemiology	1% of all men	Most common hernia in men and women M>F	Affects mostly females
Etiology	Acquired weakness of transversalis fascia "Wear and tear" Increased intra-abdominal pressure	Congenital persistence of processus vaginalis in 20% of adults	Pregnancy weakness of pelvic floor musculature Increased intra-abdominal pressure
Anatomy	Through Hesselbach's triangle **Medial** to inferior epigastric artery Usually does not descend into scrotal sac	Originates in deep inguinal ring Lateral to inferior epigastric artery Often descends into scrotal sac (or labia majora)	Into femoral canal, below inguinal ligament but may override it Medial to femoral vein within femoral canal
Treatment	Surgical repair	Surgical repair	Surgical repair
Prognosis	3-4% risk of recurrence	<1% risk of recurrence	

Table 17. Superficial Inguinal Ring vs. Deep Inguinal Ring*

Superficial Inguinal Ring	Deep Inguinal Ring
Opening in external abdominal aponeurosis; palpable superior and lateral to pubic tubercle	Opening in transversalis fascia: palpable superior to mid-inguinal ligament
Medial border: medial crus of external oblique aponeurosis	Medial border: inferior epigastric vessels
Lateral border: lateral crus of external oblique aponeurosis	Superior-lateral border: internal oblique and transversus abdominis muscles
Roof: intercrural fibres	Inferior border: inguinal ligament

*see *Basic Anatomy Review, Figure 2, GS3*

Robotic Inguinal vs. Transabdominal Laparoscopic Inguinal Hernia Repair: The RIVAL Randomized Clinical Trial
JAMA Surg. 2020;155(5):380-387
Purpose: To determine whether a robotic approach to inguinal hernia repair results in improved postoperative outcomes compared with the traditional laparoscopic inguinal hernia repairs.
Results: At preoperative, 1 wk and 30 d assessments there were no differences between the groups on wound events, readmissions, pain, or quality of life. However, the robotic approach was associated with increased cost, operative time, and surgeon frustration compared to the laparoscopic approach.
Conclusions: There is no benefit of the robotic approach compared with the laparoscopic approach.

Appendix

Appendicitis

Epidemiology
- 6% of population, M>F (1.4:1)
- 80% between ages 5-35

Pathogenesis
- luminal obstruction → bacterial overgrowth → inflammation/swelling → increased pressure → localized ischemia → gangrene/perforation → localized abscess (walled off by omentum) or peritonitis
- etiology
  - children or young adult: hyperplasia of lymphoid follicles, initiated by infection
  - adult: fibrosis/stricture, fecalith, or obstructing neoplasm
  - other causes: parasites or foreign body

Clinical Features
- most reliable feature is progression of signs and symptoms
- low-grade fever (38˚C), rises if perforation
- abdominal pain then anorexia, N/V
- classic pattern: pain initially periumbilical; constant, dull, poorly localized, then well-localized pain over McBurney's point
  - due to progression of disease from visceral irritation (causing referred pain from structures of the embryonic midgut, including the appendix) to irritation of parietal structures
- signs
  - inferior appendix: McBurney's sign (see sidebar), Rovsing's sign (palpation pressure to left abdomen causes McBurney's point tenderness). McBurney's sign is present whenever the opening of the appendix at the cecum is directly under McBurney's point; therefore McBurney's sign is present even when the appendix is in different locations
  - retrocecal appendix: psoas sign (pain on flexion of hip against resistance or passive hyperextension of hip)
  - pelvic appendix: obturator sign (flexion then external or internal rotation about right hip causes pain)

Complications
- perforation (especially if >24 h duration)
- abscess, phlegmon
- sepsis

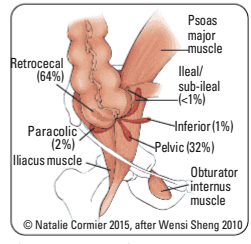

Figure 12. Appendix anatomy

McBurney's Sign
Tenderness 1/3 the distance from the ASIS to the umbilicus on the right side

Investigations
- laboratory
  - mild leukocytosis with left shift (may have normal WBC counts)
  - higher leukocyte count with perforation
  - β-hCG to rule out ectopic pregnancy
  - urinalysis
- imaging
  - U/S: may visualize appendix, but also helps rule out gynecological causes – overall accuracy 90-94%, can rule in but CANNOT rule out appendicitis (if >6 mm, SENS/SPEC/NPV/PPV 98%)
  - CT scan: thick wall, enlarged (>6 mm), wall enhancement, appendicolith, and inflammatory changes – overall accuracy 94-100%, optimal investigation

Treatment
- hydrate, correct electrolyte abnormalities
- appendectomy (gold standard)
  - laparoscopic is standard
  - complications: intra-abdominal abscess, appendiceal stump leak
  - perioperative antibiotics: cefazolin + metronidazole; if uncomplicated, perioperative dose is adequate
- consider treatment with postoperative antibiotics for perforated appendicitis
- for patients who present with an abscess (palpable mass or phlegmon on imaging and often delayed diagnosis with symptoms for >4-5 d), consider radiologic drainage + antibiotics x14 d ± interval appendectomy once inflammation has resolved = (controversial)
- medical management with antibiotic therapy should be reserved for those who are unfit for or refuse surgery
- colonoscopy in those >50 yr to rule out concurrent etiology (neoplasm)

Antibiotics versus Appendectomy for Acute Appendicitis - Longer-Term Outcomes
N Engl J Med 2021;385(25):2395. Epub 2021 Oct 25.
Purpose: Compare the efficacy of antibiotics vs. an appendectomy for acute appendicitis with respect to long-term outcomes.
Method: Randomized trial comparing antibiotic treatment with appendectomy in patients with appendicitis.
Results: The 30-day general health status of patients treated with antibiotics was comparable to the appendectomy group. However, 29 percent of medically-treated patients required appendectomy by 90 d. Longer-term data from this trial now confirm high rates of subsequent appendectomy after initial medical therapy: 40 percent at one year, 46 percent at two years, and 49 percent at three and four years.
Conclusions: Surgery should continue to be recommended for uncomplicated appendicitis and antibiotic therapy should be reserved for those who are medically unfit for or decline surgery.

Prognosis
- mortality rate: 0.09-0.24%

Inflammatory Bowel Disease
- see Gastroenterology, G22

Principles of Surgical Management
- medical management remains first line, but surgery can alleviate symptoms, address complications, and improve quality of life
- conserve bowel: resect as little as possible to avoid short gut syndrome
- perioperative management
  - optimize medical status: may require TPN (especially if >7 d NPO) and bowel rest
  - hold immunosuppressive therapy preoperative, provide preoperative stress dose of corticosteroid; if patient had recent steroid therapy, taper steroids postoperative
  - VTE prophylaxis: LMWH or heparin (IBD patients at increased risk of thromboembolic events)

Crohn's Disease
- see Gastroenterology, G23

Crohn's 3 Major Patterns
- Ileocecal 40% (RLQ pain, fever, weight loss)
- Small intestine 30% (especially terminal ileum)
- Colon 25% (diarrhea)

Findings in Crohn's
- "Cobblestoning" on mucosal surface due to edema and linear ulcerations
- "Skip lesions": normal mucosa in between
- "Creeping fat": mesentery infiltrated by fat
- Granulomas: 25-30%

Treatment
- surgery is for symptom management; it is NOT curative, but over lifetime ~70% of Crohn's patients will have surgery
- indications for surgical management
  - failure of medical management
  - SBO (due to stricture/inflammation): indication in 50% of surgical cases
  - abscess, fistula (enterocolic, vesicular, vaginal, cutaneous abscess), quality of life, perforation, hemorrhage, chronic disability, failure to thrive (children), and perianal disease
- surgical procedures
  - resection and anastomosis/stoma if active or subacute inflammation, perforation, or fistula
  - surgery should be attempted in the elective setting ideally off steroids
- resection margin only has to be free of gross disease (microscopic disease irrelevant to prognosis)
  - stricturoplasty – widens lumen in chronically scarred bowel: relieves obstruction without resecting bowel (contraindicated in acute inflammation)

Complications of Treatment
- anastomotic leak
- dehydration
- short gut syndrome (diarrhea, steatorrhea, malnutrition)
- fistulas
- gallstones (if terminal ileum resected, decreased bile salt resorption → increased cholesterol precipitation)
- kidney stones (loss of calcium in diarrhea → increased oxalate absorption and hyperoxaluria → stones)

Prognosis
- recurrence rate at 10 yr: ileocolic (25-50%), small bowel (50%), colonic (40-50%)
- re-operation at 5 yr: primary resection (20%), bypass (50%), stricturoplasty (10% at 1 yr)
- 80-85% of patients who need surgery lead normal lives
- mortality: 15% at 30 yr

Ulcerative Colitis

- see Gastroenterology, G25

Treatment
- indications for surgical management
  - failure of medical management (including inability to taper steroids)
  - complications: hemorrhage, obstruction, perforation, toxic megacolon (emergency), failure to thrive (children)
  - reduce cancer risk (1-2% risk per yr after 10 yr of disease)
- surgical procedures
  - proctocolectomy and ileal pouch-anal anastomosis (IPAA) ± rectal mucosectomy (operation of choice)
  - proctocolectomy with permanent end ileostomy (if not a candidate for ileoanal procedures)
  - colectomy and IPAA ± rectal mucosectomy
  - in emergency: total colectomy and ileostomy with Hartmann closure of the rectum, rectal preservation

Complications of Treatment
- early: bowel obstruction, transient urinary dysfunction, dehydration (high stoma output), anastomotic leak
- late: stricture, anal fistula/abscess, pouchitis, poor anorectal function, reduced fertility

Prognosis
- mortality: 5% over 10 yr
- total proctocolectomy will eliminate risk of cancer
- perforation of the colon is the leading cause of death from UC

LARGE INTESTINE

Large Bowel Obstruction

Mechanical Large Bowel Obstruction

Etiology

Table 18. Common Causes of LBO

Intraluminal	Intramural	Extramural
Constipation	Adenocarcinoma	Volvulus
Foreign bodies	Diverticulitis (edema, stricture)	Adhesions
	IBD stricture	Hernias (sigmoid colon in a large groin hernia)
	Radiation stricture	

Top 3 Causes of LBO (in order)
- Cancer (>60%)
- Volvulus (10-15%)
- Diverticulitis (10%)

In a patient with a clinical LBO consider impending perforation when:
- Cecum ≥12 cm in diameter
- Tenderness present over cecum

Clinical Features (unique to LBO)
- open loop (10-20%)
  - incompetent ileocecal valve allows relief of colonic pressure as contents reflux into ileum, therefore clinical features similar to SBO
- closed loop (80-90%) (dangerous)
  - competent ileocecal valve, resulting in proximal and distal occlusions
  - massive colonic distention → increased pressure in cecum → bowel wall ischemia → necrosis → perforation

Investigations
- CBC with differential, BUN, electrolyte panel, creatinine, CEA if patient is suspected to have malignancy, and lactate for level of ischemia
- imaging: AXR and CT scan

Treatment
- supportive management: IV fluids, gastrointestinal decompression
- surgical intervention (75% of cases)
  - volvulus: initial decompression with flexible sigmoidoscopy, operative reduction or sigmoid resection dependent on severity
  - colorectal obstruction: ostomy alone (fecal diversion), colectomy with primary anastomosis, or Hartmann procedure
- may pursue stenting as a bridge to surgery or palliation

Prognosis
- overall mortality: 10%
- cecal perforation + feculent peritonitis: 20% mortality

Table 19. Bowel Obstruction vs. Paralytic Ileus

	SBO	LBO	Paralytic Ileus
N/V	Early, may be bilious	Late, may be feculent	Present
Abdominal Pain	Colicky	Colicky	Minimal or absent
Abdominal Distention	+ (prox SBO), ++ (distal SBO)	++	+
Constipation	+	+	+
Bowel Sounds	Normal, increased Absent if secondary ileus (delayed presentation)	Normal, increased (borborygmi) Absent if secondary ileus (delayed presentation)	Decreased, absent
AXR Findings	Air-fluid levels "Ladder" pattern (plicae circulares) Proximal distention (>3 cm) + no colonic gas	Air-fluid levels "Picture frame" appearance Proximal distention + distal decompression No small bowel air if competent ileocecal valve Coffee bean sign (sigmoid volvulus)	Air throughout small bowel and colon

Functional Large Bowel Obstruction: Colonic Pseudo-Obstruction (Ogilvie's Syndrome)

Definition
- acute pseudo-obstruction
- distention of colon without mechanical obstruction in distal colon
- exact mechanism unknown, likely autonomic motor dysregulation

Associations
- most common: trauma, infection, and cardiac (MI, CHF)
- disability (long-term debilitation, chronic disease, bed-bound nursing home patients, and paraplegia), drugs (narcotic use, laxative abuse, and polypharmacy), and other (recent orthopedic or neurosurgery, post-partum, electrolyte abnormalities including hypokalemia, retroperitoneal hematoma, and diffuse carcinomatosis)

Clinical Features
- classically presents with abdominal distention (acute or gradual over 3-7 d)
- abdominal pain, N/V, constipation or diarrhea
- watch out for fever, leukocytosis, and presence of peritoneal signs (suggestive of colonic ischemia or perforation)

Investigations
- AXR: cecal dilatation (if diameter ≥12 cm, increased risk of perforation)

Treatment
- treat underlying cause
- NPO, NG tube
- decompression: rectal tube, colonoscopy, neostigmine (cholinergic drug), or surgical (ostomy/resection)
- surgery (extremely rare): if perforation, ischemia, or failure of conservative management

Prognosis
- most resolve with conservative management

Diverticular Disease

Definitions
- diverticulum: abnormal outpouching from the wall of a hollow organ
- diverticulosis: presence of multiple diverticula
- diverticulitis: inflammation of diverticula
- true (congenital) diverticuli: contain all layers of colonic wall, often right-sided
- false (acquired) diverticuli: contain mucosa and submucosa, often left-sided

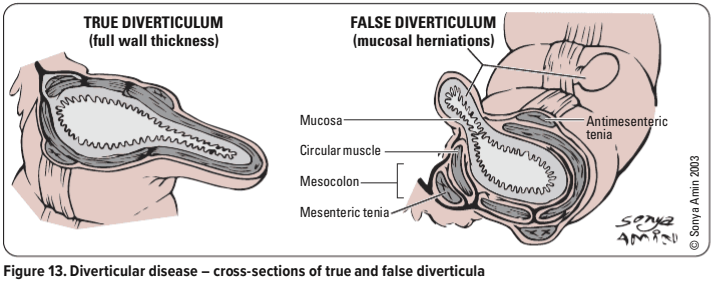

Figure 13. Diverticular disease – cross-sections of true and false diverticula

Diverticulosis

Epidemiology
- 5-50% of Western population, lower incidence in non-Western countries, M=F
- prevalence is age dependent: <5% by age 40, 30% by age 60, 65% by age 85
- 95% involve sigmoid colon (site of highest pressure)

Diverticulosis vs. Diverticulitis
Diverticulosis represents the presence of diverticuli (bulging pouches) within the colonic wall, whereas diverticulitis is the inflammation of one or more diverticuli

Pathogenesis
- risk factors
  - lifestyle: diet (low-fibre, high fat, red meat), inactivity, and obesity
  - muscle wall weakness from aging and illness (e.g. Ehlers-Danlos, Marfan's)
- high intraluminal pressures cause outpouching to occur at points of greatest weakness, most commonly where vasa recta penetrate the circular muscle layer leading to an increased risk of hemorrhage

Clinical Features
- uncomplicated diverticulosis: asymptomatic (70-80%)
- episodic abdominal pain (often LLQ), bloating, flatulence, constipation, diarrhea
- absence of fever/leukocytosis
- no physical exam findings or poorly localized LLQ tenderness
- complications:
  - diverticulitis (15-25%): 25% of which are complicated (i.e. abscess, obstruction, perforation, fistula)
  - bleeding (5-15%): PAINLESS rectal bleeding, 30-50% of massive LGIB
  - diverticular colitis (rare): diarrhea, hematochezia, tenesmus, and abdominal pain

Treatment
- uncomplicated diverticulosis: high fibre, education
- diverticular bleed
  - initially workup and treat as any LGIB
  - if hemorrhage does not stop, resect involved region

Diverticulitis

Epidemiology
- 95% left-sided in patients of Western countries, 75% right-sided in Asian populations

Pathogenesis
- erosion of the wall by increased intraluminal pressure or inspissated food particles → inflammation and focal necrosis → micro or macroscopic perforation
- usually mild inflammation with perforation walled off by pericolic fat and mesentery; abscess, fistula, or obstruction can ensue
- poor containment results in free perforation and peritonitis

Clinical Features

- depend on severity of inflammation and whether or not complications are present; hence ranges from asymptomatic to generalized peritonitis
- LLQ pain/tenderness (2/3 of patients) often for several days before admission
- constipation, diarrhea, N/V, and urinary symptoms (with adjacent inflammation)
- low-grade fever, mild leukocytosis, and occult or gross blood in stool rarely coexist with acute diverticulitis
- complications (25% of cases)
  - abscess: palpable, tender abdominal mass
  - fistula: colovesical (most common), coloenteric, colovaginal, and colocutaneous
  - colonic obstruction: related to colonic strictures secondary to scarring from repeated inflammation
  - perforation: generalized peritonitis (feculent vs. purulent)
- recurrent attacks rarely lead to peritonitis

Investigations

- CT scan (test of choice)
  - very useful for assessment of severity and prognosis (97% sensitive, 99% specific)
  - usually done with rectal contrast
  - increased soft tissue density within pericolic fat secondary to inflammation, diverticula secondary to inflammation, bowel wall thickening, soft tissue mass (pericolic fluid, abscesses), and fistula
  - 10% of diverticulitis cannot be distinguished from carcinoma
- AXR, upright CXR
  - localized diverticulitis (ileus, thickened wall, SBO, and partial colonic obstruction)
  - free air may be seen in 30% with perforation and generalized peritonitis
- colonoscopy or barium enema and flexible sigmoidoscopy (elective evaluation)
  - establish extent of disease and rule out other diagnoses (polyps and malignancy) AFTER resolution of acute episode

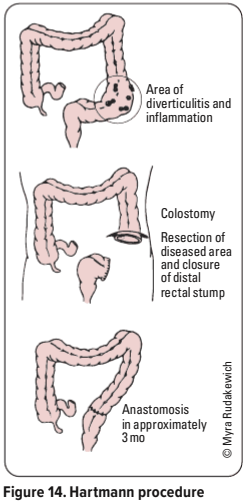
Treatment

- uncomplicated: conservative management
- outpatient: clear fluids only until improvement. Avoid treatment with antibiotics for those with uncomplicated acute diverticulitis
- hospitalize: if severe presentation, inability to tolerate oral intake, significant comorbidities, or fail to improve with outpatient management
  - treat with NPO, IV fluids, and IV antibiotics (e.g. IV ceftriaxone + metronidazole)
- image-guided (CT) percutaneous drainage of abscesses reduces the urgency of surgical resection in most patients
- surgery:
  - indications:
    - unstable patient with peritonitis
    - Hinchey stage 3-4 (see *Table 20*)
    - after 1 attack if immunosuppressed
    - consider if recurrent episodes of diverticulitis (≥3); recent trend is toward conservative management of recurrent mild/moderate attacks
  - procedures:
    - Hartmann resection (for unstable or complex cases)
    - colon resection + colostomy and rectal stump → colostomy reversal in 3-6 mo
  - for more stable patients with Hinchey stage 3 and 4 acute diverticulitis: colonic resection, primary anastomosis + diverting loop ileostomy is becoming more common, with benefits for mortality and morbidity
  - for Hinchey stage 3: laparoscopic peritoneal lavage with drain placement near the affected colon, in addition to 4 antibiotics (NO resection), has been proposed
  - complications: perforation, abscess, fistula, obstruction, hemorrhage, inability to rule out colon cancer on endoscopy, or failure of medical management

Prognosis

- mortality rates: 6% for purulent peritonitis, 35% for feculent peritonitis
- recurrence rates: 13-30% after first attack, 30-50% after second attack

Efficacy and Safety of Nonantibiotic Outpatient Treatment in Mild Acute Diverticulitis (DINAMO-study): A Multicentre, Randomised, Open-label, Noninferiority Trial
Ann Surg 2021;274(5):e435
Background: In recent years, it has shown no benefit of antibiotics (ATB) in the treatment of uncomplicated Acute Diverticulitis in hospitalized patients.
Methods: Prospective, multicentre, open-label, noninferiority, randomized controlled trial.
Results: Differences in hospitalization rates, revisits, and poor pain control at 2 d follow-up were within the non-inferiority margin.
Conclusions: Nonantibiotic outpatient treatment of mild AD is safe and effective and is not inferior to current standard treatment.



Area of diverticulitis and inflammation
Colostomy
Resection of diseased area and closure of distal rectal stump
Anastomosis in approximately 3 mo
© Myra Rudakewich

Figure 14. Hartmann procedure

Table 20. Hinchey Staging and Treatment for Diverticulitis

Hinchey Stage	Description	Acute Treatment
1	Phlegmon/small pericolic abscess	Medical
2	Large abscess/fistula	Medical, abscess drainage ± resection with primary anastomosis
3	Purulent peritonitis (ruptured abscess)	Resection or Hartmann procedure
4	Feculent peritonitis	Hartmann procedure

Colorectal Neoplasms

Colorectal Polyps

Definition
- polyp: protuberance into the lumen of normally flat colonic mucosa
  - sessile (flat) or pedunculated (on a stalk)

Epidemiology
- 30% of the population have polyps by age 50, 40% by age 60, 50% by age 70; M>F

Clinical Features
- 50% in the rectosigmoid region, 50% are multiple
- usually asymptomatic, do not typically bleed, tenesmus, intestinal obstruction, and mucus
- usually detected during routine endoscopy or familial/high-risk screening

Pathology
- non-neoplastic/non-adenomatous
  - hyperplastic: most common non-neoplastic polyp
  - mucosal polyps: small <5 mm, no clinical significance
  - hamartomas: juvenile polyps (large bowel), Peutz-Jegher syndrome (small bowel)
    - malignant risk due to associated adenomas (large bowel)
    - low malignant potential → most spontaneously regress or autoamputate
  - inflammatory pseudopolyps: associated with IBD, no malignant potential
  - submucosal polyps: lymphoid aggregates, lipomas, leiomyomas, and carcinoids
- neoplastic/adenomatous
  - adenomas: premalignant, considered carcinoma *in situ* if high-grade dysplasia
    - may contain invasive carcinoma ("malignant polyp" – 3-9%): invasion into submucosa
    - malignant potential related to histological type: villous > tubulovillous > tubular

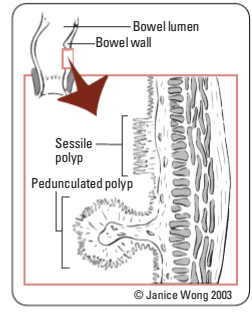


Figure 15. Sessile and pedunculated polyps

Table 21. Characteristics of Tubular vs. Villous Polyps

	Tubular	Villous
Incidence	Common (60-80%)	Less common (10%)
Size	Small (<2 cm)	Large (usually >2 cm)
Attachment	Pedunculated	Sessile
Malignant Potential	Lower	Higher
Distribution	Even	Left-sided predominance

Investigations
- colonoscopy with biopsy/resection (gold standard)
- CT colonography: increasing in availability; patients still require bowel prep and will require colonoscopy if polyps are identified
- other: flexible sigmoidoscopy (if polyps are detected, proceed to colonoscopy for examination of entire bowel and biopsy)

Treatment
- indications: symptoms, malignancy or risk of malignancy (i.e. adenomatous polyps)
- endoscopic removal of entire growth
- indications for segmental resection for malignant polyps: 1) lymphovascular invasion; 2) tumour budding; 3) positive resection margin; 4) poorly differentiated cells; 5) evidence of regional or distant metastases on staging
  - most of these cases are usually discussed at multidisciplinary tumour boards
- follow-up endoscopy:
  - every 5 yr: if low-risk polyp (<10 mm tubular adenoma or <10 mm sessile serrated without dysplasia)
  - every 3 yr: if high-risk polyp (3-10 tubular adenomas, >10 mm tubular or serrated polyp, adenoma with villous features or high grade dysplasia, or sessile serrated with dysplasia)

Familial Colon Cancer Syndromes

FAMILIAL ADENOMATOUS POLYPOSIS

Epidemiology
- accounts for <1% of colorectal cancers, affects males and females equally

Pathogenesis
- autosomal dominant inheritance, mutation in adenomatous polyposis coli (APC) gene

Clinical Features
- hundreds to thousands of colorectal adenomas usually by age 20 (by 40's in attenuated FAP)
- virtually 100% lifetime risk of colon cancer (due to number of polyps)
- extracolonic manifestations
  - bile duct, pancreas, stomach, thyroid (large benign multinodular goitre), adrenal glands, and small bowel
  - congenital hypertrophy of retinal pigment epithelium presents early in life in 2/3 of patients; 97% sensitivity
- variants
  - Gardner's syndrome: FAP + extra-intestinal lesions (sebaceous cysts, osteomas, desmoid tumours)
  - Turcot syndrome: FAP + central nervous system tumours (childhood cerebellar medulloblastoma)

Investigations
- genetic testing (80-95% sensitive, 99-100% specific)
- if no polyposis found: annual flexible sigmoidoscopy from puberty to age 50, then routine screening
- if polyposis or APC gene mutation found: annual colonoscopy, consider surgery, and consider upper endoscopy to evaluate for periampullary tumours

Treatment
- surgery indicated by ages 17-20
- total proctocolectomy with ileostomy or total colectomy with ileorectal anastomosis
- doxorubicin-based chemotherapy
- NSAIDs for intra-abdominal desmoids

Referral Criteria for Genetic Screening for APC
- To confirm the diagnosis of FAP (in patients with ≥100 colorectal adenomas)
- To provide pre-symptomatic testing for individuals at risk for FAP (1st degree relatives who are ≥10 yr)
- To confirm the diagnosis of attenuated FAP (in patients with ≥20 colorectal adenomas)

HEREDITARY NON-POLYPOSIS COLORECTAL CANCER – LYNCH SYNDROME

Epidemiology
- most common inherited colorectal cancer susceptibility syndrome and accounts for 3% of colorectal cancer diagnoses

Pathogenesis
- autosomal dominant inheritance, mutation in a DNA mismatch repair gene (MSH2, MSH6, MLH1, PMS2) resulting in microsatellite genomic instability and subsequent mutations
- microsatellite instability account for approximately 15% of all CRCs

Clinical Features
- early age of onset, right > left colon, synchronous and metachronous lesions
- mean age of cancer presentation is 44 yr, lifetime risk 70-80%; M>F
  - HNPCC I: hereditary site-specific colon cancer
  - HNPCC II: cancer family syndrome → high rates of extracolonic tumours (endometrial, ovarian, hepatobiliary, small bowel, adrenal)

Diagnosis
- Amsterdam Criteria ("3-2-1 rule")
  - 3 or more relatives with verified Lynch syndrome associated cancers, and 1 must be 1st degree relative of the other 2
  - 2 or more generations involved
  - 1 case must be diagnosed before 50 yr
  - FAP is excluded
- genetic testing (80% sensitive)
  - refer individuals for genetic screening if they fulfill either the Amsterdam Criteria or the revised Bethesda Criteria
- colonoscopy (starting age 20) annually
- surveillance for extracolonic lesions

Treatment
- total colectomy and ileorectal anastomosis with annual proctoscopy

Revised Bethesda Criteria for HNPCC and Microsatellite Instability (MSI)
Tumours from individuals should be tested for MSI in the following situations:
- Colorectal cancer diagnosed in a patient who is <50 yr
- Presence of synchronous, metachronous, colorectal, or other HNPCC-associated tumours, regardless of age
- Colorectal cancer with the MSI-H histology diagnosed in a patient who is <60 yr
- Colorectal cancer diagnosed in one or more first-degree relatives with an HNPCC-related tumour, with one of the cancers being diagnosed <50 yr
- Colorectal cancer diagnosed in two or more first- or second-degree relatives with HNPCC-related tumours, regardless of age

Elderly persons who present with iron-deficiency anemia should be investigated for colon cancer

APR removes distal sigmoid colon, rectum, and anus; permanent end colostomy required
LAR removes distal sigmoid and rectum with anastomosis of distal colon to distal rectum/anus

Colorectal Carcinoma

Epidemiology
- 3rd most common cancer (lung > breast > colon), 2nd most common cause of cancer death

Risk Factors
- most patients have no specific risk factors
- ages >50 (dominant risk factor in sporadic cases), mean age is 70
- genetic: FAP, HNPCC, or family history of CRC
- colonic conditions
  - adenomatous polyps (especially if >1 cm, villous, multiple)
  - IBD (especially UC: risk is 1-2%/yr if UC >10 yr)
  - previous colorectal, gonadal, or breast cancer
- diet (increased fat, red meat, decreased fibre) and smoking
- DM and acromegaly (insulin and IGF-1 are growth factors for colonic mucosal cells)

Pathogenesis
- adenoma-carcinoma sequence; rarely arise de novo

Clinical Features
- often asymptomatic
- hematochezia/melena, abdominal pain, and change in bowel habits
- others: weakness, anemia, weight loss, palpable mass, and obstruction
- 20% patients have distant metastatic disease at time of presentation
- spread
  - direct extension, lymphatic, and hematogenous (liver most common, lung, bone, and brain; tumour of distal rectum → IVC → lungs)
  - peritoneal seeding: ovary and Blumer's shelf (pelvic cul-de-sac)

Table 22. Clinical Features of CRC

	Right Colon	Left Colon	Rectum
Frequency	25%	35%	30%
Pathology	Exophytic lesions with occult bleeding	Annular, invasive lesions	Ulcerating
Symptoms	Weight loss, weakness, rarely obstruction	Constipation ± overflow (alternating bowel patterns), abdominal pain, decreased stool calibre, rectal bleeding	Obstruction, tenesmus, rectal bleeding
Signs	Fe-deficiency anemia, RLQ mass (10%)	BRBPR, LBO	Palpable mass on DRE, BRBPR

Investigations
- colonoscopy (gold standard): look for synchronous lesions (3-5% of patients)
  - if a patient is FOBT positive, has microcytic anemia, or has a change in bowel habits → colonoscopy
  - alternative: air contrast barium enema ("apple core" lesion) + sigmoidoscopy
- laboratory: CBC, U/A, LFTs, CEA (preoperative for baseline, >5 ng/mL have worse prognosis)
- staging: CT chest/abdomen/pelvis; bone scan and CT head only if lesions suspected
- rectal cancer: pelvic MRI or endorectal U/S to determine T and N stage

Table 23. TNM Classification System for Staging of Colorectal Carcinoma (AJCC/UICC 8th edition)

Primary Tumour (T)		Regional Lymph Nodes (N)		Distant Metastasis (M)	
Tx	Primary tumour cannot be assessed	**Nx**	Regional nodes cannot be assessed	**M0**	No distant metastasis
T0	No primary tumour found	**N0**	No regional node metastasis and no tumour deposits	**M1a**	Distant metastasis to 1 organ or site and no peritoneal metastasis
Tis	Carcinoma *in situ*, limited to intraepithelial or invasive lamina propria	**N1a**	Metastasis in 1 regional node	**M1b**	Distant metastasis to >1 (2 or more organs sites) and no peritoneal metastasis
T1	Invasion into submucosa	**N1b**	Metastasis in 2-3 regional nodes	**M1c**	Metastasis to peritoneal surface
T2	Invasion into muscularis propria	**N1c**	No regional node metastasis; tumour deposits were submucosal, mesangial or peritoneum-covered para-colorectal tissue		
T3	Invasion through muscularis propria and into pericolorectal tissues	**N2a**	Metastasis in 4-6 regional nodes		
T4a	Invasion through visceral peritoneum	**N2b**	Metastasis in ≥7 regional nodes		
T4b	Invasion or adherent to other organs or structures				

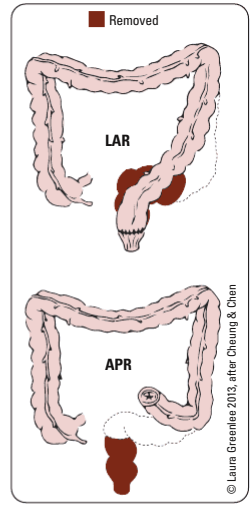

Figure 16. APR vs. LAR

5 Year Survival Rates for CRC

Stage	20-64 yr	≥65 yr
I	95.2%	89.1%
IIA	89.6%	84.4%
IIB	67.6%	55%
IIIA	91.3%	85.1%
IIIB	76.9%	64.6%
IIIC	61.8%	45.5%
IV	14.2%	7.4%

Preoperative vs. Postoperative Chemoradiotherapy for Locally Advanced Rectal Cancer: Results of the German CAO/ARO/AIO-94 Randomized Phase III Trial after a Median Follow-Up of 11 Yr

J Clin Oncol 2012;30:1926-1933

Background: The CAO/ARO/AIO-94 trial (published 2004) recommended preoperative chemoradiotherapy (CRT) as standard treatment for locally advanced rectal cancer. However, no survival benefit was shown after median follow-up of 46 mo, and this study reports long-term effects.

Methods: Patients with stage II to III rectal cancer (n=799) were randomly assigned to preoperative (n=404) or postoperative CRT (n=395) with fluorouracil (FU), radiation, and adjuvant FU chemotherapy, in addition to total mesorectal excision surgery. Follow-up was designed to assess long-term overall survival as the primary endpoint and cumulative incidence of local and distant relapses as well as disease-free survival as secondary endpoints.

Results: 10 yr incidence of local relapse was significantly lower in the preoperative CRT group than in the postoperative group (7.1% vs. 10.1%, P=0.048). Overall survival at 10 yr was similar at ~60% for patients treated with preoperative or postoperative CRT (P=0.85). Disease-free survival rates at 10 yr was similar at ~68% for patients treated with preoperative or postoperative CRT (P=0.54). No significant difference was detected for 10 yr incidence of distant metastases (preoperative CRT 29.8% vs. postoperative CRT 29.6%, P=0.9).

Conclusion: There is long-term reduction in local recurrence of stage II to III rectal cancer with preoperative chemotherapy, but no improvement in overall survival or distant recurrence of disease.

Treatment
- colon cancer
  - wide surgical resection of lesion according to vascular distribution and regional lymphatic drainage; usually colectomy with primary anastomosis
  - curative: wide resection of lesion (5 cm margins) with nodes (>12) and mesentery
  - care is taken to not spread tumour by unnecessary palpation
  - adjuvant chemotherapy (oxaliplatin-based) for stage III and is considered in select stage II patients
  - palliative: if distant spread, local control for hemorrhage or obstruction
- metastatic lesions confined to the liver can be resected with curative intent
- rectal cancer
  - choice of operation depends on individual case
    - LAR: curative procedure of choice if adequate distal margins (~2 cm); uses technique of total mesorectal excision
      - APR: if adequate distal margins cannot be obtained; involves the removal of distal sigmoid colon, rectum, and anus permanent end colostomy required
    - transanal minimally invasive surgery (TAMIS): local excision for select T1 lesions only
  - palliative procedures involve proximal diversion with an ostomy for obstruction and radiation for bleeding or pain
  - combined neoadjuvant chemoradiation therapy followed by postoperative adjuvant chemotherapy for stages II and III

Follow-Up
- stage I: mixed recommendations; either routine colonoscopy or screening like stage II & III
- stage II & III: regular follow-up q3-6 mo for 3 yr, then q6 mo until 5 yr, with regular measurement of serum CEA for at least 3 yr; annual CT chest/abdo/pelvis for at least 3 yr; colonoscopy at 1, 3, and 5 yr
- stage IV: no data on surveillance strategy

Other Conditions of the Large Intestine

Angiodysplasia

Definition
- vascular malformation: focal submucosal venous dilatation and tortuosity

Clinical Features
- most frequently in right colon of patients >60 yr
- predisposition in end-stage renal disease, and Von Willebrand disease, and aortic stenosis
- bleeding typically intermittent, rarely massive, and not usually hypotensive (melena, anemia, and occult blood positive stools)
- >90% of cases cease bleeding spontaneously

Investigations
- colonoscopy: cherry red spots, branching pattern from central vessel
- angiography: early-filling vein, vascular tuft, and delayed emptying vein; rarely active bleeding
- RBC technetium-99 scan
- barium enema is contraindicated (obscures other x-rays, i.e. angiogram)

Treatment
- none if asymptomatic
- cautery, embolization, vasopressin infusion, sclerotherapy, band ligation, laser, octreotide, and rarely segmental resection if other treatments fail

Volvulus

Definition
- rotation of segment of bowel about its mesenteric axis
- sigmoid (65%), cecum (30%), transverse colon (3%), and splenic flexure (2%)
  - elderly >70 yr (sigmoid), adult 40-60yr (cecal), and neonates and infants (midgut)
- 5-10% of large bowel obstructions; 25% of intestinal obstructions during pregnancy

Risk Factors
- age (50% of patients >70 yr: stretching/elongation of bowel with age)
- high fibre diet (can cause elongated/redundant colon), chronic constipation, laxative abuse, pregnancy, bedridden, and institutionalization (less frequent evacuation of bowels)
- megacolon
- intestinal bands/adhesions

Cecal Volvulus
AXR: Central cleft of "coffee bean" sign points to RLQ

Sigmoid Volvulus
AXR: Central cleft of "coffee bean" sign points to LLQ
Barium enema: "ace of spades" or "bird's beak" sign

Clinical Features
- symptoms due to bowel obstruction (see *Large Bowel Obstruction, GS37*) or intestinal ischemia (see *Intestinal Ischemia, GS31*)
- colicky abdominal pain, persistence of pain between spasms, abdominal distention, and vomiting

Investigations
- AXR (classic findings): "omega," "bent inner-tube," "coffee-bean" signs, multiple air-fluid levels
- barium/Gastrografin® enema: "ace of spades" (or "bird's beak") appearance due to funnel-like luminal tapering of lower segment towards volvulus
- sigmoidoscopy or colonoscopy as appropriate
- CT: "whirl pattern" of mesenteric vessels twisting about the volvulus axis
  - barium contrast and colonoscopy are contraindicated due to risk of perforation

Treatment
- initial supportive management same as initial management for bowel obstruction (see *Large Bowel Obstruction, GS37*)
- cecum
  - colonoscopic detorsion and decompression; successful 15-20% of cases
  - surgical
    - right colectomy + ileotransverse colonic anastomosis
- sigmoid
  - decompression by flexible sigmoidoscopy and insertion of rectal tube past obstruction
  - subsequent elective surgery recommended (50-70% recurrence)
  - surgical
    - surgical resection with or without primary anastomosis
    - indications for urgent surgical management: strangulation, perforation, or unsuccessful endoscopic decompression

Toxic Megacolon

Pathogenesis
- extension of inflammation into smooth muscle layer causing paralysis and leading to nonobstructive colonic dilatation
- damage to myenteric plexus and electrolyte abnormalities are not consistently found

Etiology
- IBD (UC > Crohn's disease)
- infectious colitis: bacterial (*C. difficile, Salmonella, Shigella*, and *Campylobacter*), viral (cytomegalovirus), and parasitic (E. histolytica)

Clinical Features
- infectious colitis usually presents for >1 wk before colonic dilatation
- diarrhea ± blood (sudden improvement of diarrhea may signify onset of megacolon)
- abdominal distention, tenderness, ± local/general peritoneal signs (suggests perforation)
- triggers: hypokalemia, constipating agents (opioids, antidepressants, loperamide, and anticholinergics), barium enema, and colonoscopy

Diagnostic Criteria
- must have both colitis and systemic manifestations for diagnosis
- radiologic evidence of dilated colon >6 cm, and
- three of: fever, HR >120, WBC >10.5, anemia and
- one of: dehydration, electrolyte disturbances, hypotension, or altered LOC

Investigations
- CBC (leukocytosis with left shift and anemia from bloody diarrhea), electrolytes, elevated c-reactive protein, and ESR
  - metabolic alkalosis (volume contraction and hypokalemia) and hypoalbuminemia are late findings
- AXR: dilated colon >6 cm (right > transverse > left), loss of haustra
- CT: useful to assess underlying disease severity and possible complications (i.e. abscess, perforation, ascending pylephlebitis)

Treatment
- NPO, NG tube, stop constipating agents, correct fluid and electrolyte abnormalities, and transfusion
- serial AXRs
- broad-spectrum antibiotics (reduce sepsis and anticipate perforation)
- aggressive treatment of underlying disease (e.g. steroids in IBD and metronidazole for *C. difficile*)
- indications for surgery (50% improve on medical management)
  - worsening or persisting toxicity or dilation after 48-72 h
  - severe hemorrhage, perforation
  - high lactate and WBC, especially for *C. difficile*
- procedure: subtotal colectomy + end ileostomy (possible re-anastomosis later)

Use caution when giving antidiarrheal agents, especially with bloody diarrhea

Prognosis
- 25-30% mortality

Fistula

Definition
- abnormal communication between two epithelialized surfaces (e.g. enterocutaneous, colovesical, aortoenteric, and entero-enteric)

Etiology
- foreign object erosion (e.g. drainage tube, gallstone, graft)
- inflammatory states (e.g. infection, IBD (Crohn's > UC), and diverticular disease)
- iatrogenic/surgery (e.g. postoperative anastomotic leak and radiation)
- congenital, trauma
- neoplastic

Why Fistulae Stay Open

FRIENDO
Foreign body
Radiation
Infection
Epithelialization
Neoplasm
Distal obstruction (most common)
Others: increased flow; steroids (may inhibit closure, usually will not maintain fistula)

Investigations
- U/S, CT scan, fistulogram
- measure amount of drainage from fistula

Treatment
- decrease secretion: octreotide/somatostatin/omeprazole
- surgical intervention: dependent upon etiology (for non-closing fistulas)

Stomas

Definition
- an opening of the GI tract onto the surface of the abdomen wall
  - end stomas: the proximal end of the GI tract forms the stoma and the distal end of the GI tract is not part of the stoma
  - loop stomas: a loop of the GI tract is brought up to the skin and the antimesenteric surface of the bowel is matured as a stoma

Colostomy/Ileostomy
- Connection of proximal limb of colon or ileum to abdominal wall skin
- Mucous fistula
- Connection of distal limb of resection margin to abdominal wall skin
- Ileal Conduit
- Connection of bowel to ureter proximally and abdominal wall distally to drain urine

Ileostomy
- usually positioned in RLQ; ileum is brought through rectus abdominis muscles
- indications: after proctocolectomy for UC, some cases of Crohn's disease or familial polyposis
- conventional ileostomy: discharges small quantities of liquid material continuously, appliance (plastic bag attached to a sheet of protective material) required at all times
- continent ileostomy: reservoir is constructed from distal ileum (ileal pouch anal anastomosis)

Colostomy
- indications: to decompress an obstructed colon, to protect a distal anastomosis after resection, or to evacuate stool after distal colon or rectum is removed
- colostomies can be done by making an opening in a loop of colon (loop colostomy) or by dividing the colon and bringing out one end (end colostomy)
- most common permanent colostomy is a sigmoid colostomy (expels stool/digital removal of feces)
- chronic paracolostomy hernia is a common complication

Complications (10%)
- obstruction: herniation, stenosis (skin and abdominal wall), adhesive bands, volvulus
- peri-ileostomy abscess and fistula
- skin irritation
- prolapse or retraction
- diarrhea (excessive output), which may lead to fluid, electrolyte, and nutritional imbalances

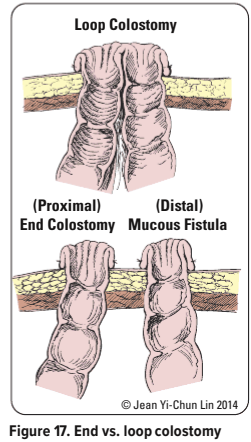

Figure 17. End vs. loop colostomy

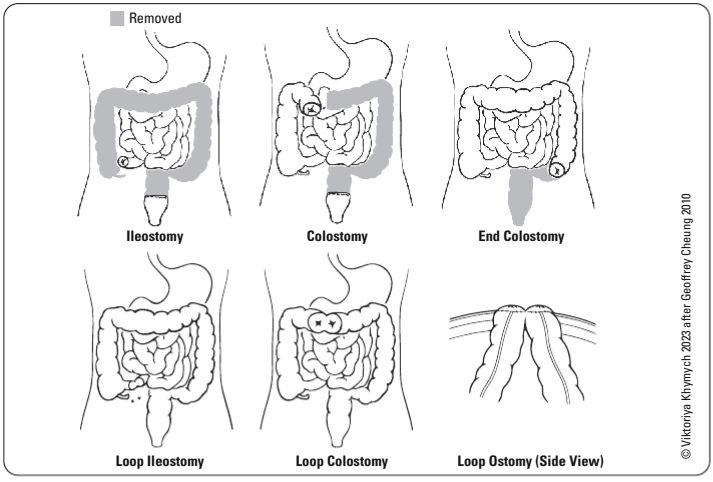

Figure 18. Ostomies

Anorectum

Hemorrhoids

Etiology
- vascular and connective tissue complexes form a plexus of dilated veins (cushion)
- internal: superior hemorrhoidal veins, above dentate line, portal circulation
- external: inferior hemorrhoidal veins, below dentate line, systemic circulation

Risk Factors
- increased intra-abdominal pressure: chronic constipation, pregnancy, obesity, portal HTN, heavy lifting

Clinical Features and Treatment
- internal hemorrhoids
  - engorged vascular cushions usually at 3, 7, 11 o'clock positions (patient in lithotomy position)
  - painless rectal bleeding, anemia, prolapse, mucus discharge, pruritus, burning pain, and rectal fullness
    - **1st degree**: bleed but do not prolapse through the anus
      - treatment: high fibre/bulk diet, sitz baths, steroid cream (short course), pramoxine (Anusol®), phlebotonics, rubber band ligation, sclerotherapy, and photocoagulation
    - **2nd degree**: bleed, prolapse with straining, and spontaneous reduction
      - treatment: rubber band ligation, and photocoagulation
    - **3rd degree**: bleed, prolapse, and require manual reduction
      - treatment: same as 2nd degree, but may require closed hemorrhoidectomy
    - **4th degree**: bleed, permanently prolapsed, and cannot be manually reduced
      - treatment: closed hemorrhoidectomy
- external hemorrhoids
  - dilated venules usually mildly symptomatic
    - pain after bowel movement, associated with poor hygiene
    - medical treatment: dietary fibre, stool softeners, steroid cream (short course), pramoxine (Anusol®), phlebotonics, and avoid prolonged straining
  - thrombosed hemorrhoids are very painful
    - resolve within 2 wk, may leave excess skin = perianal skin tag
    - treatment: consider surgical decompression within first 48 h of thrombosis, otherwise medical treatment
- indications for referral for endoscopic evaluation: history of melena, postural vital sign abnormalities, constitutional symptoms suggestive of malignancy, and family history of inherited colorectal syndromes

Prevention
- high fibre diets, prevent constipation, stool softeners

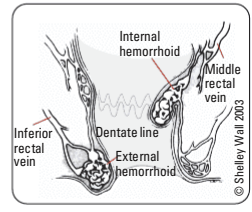

Figure 19. Hemorrhoids

Always rule out more serious causes (e.g. colon cancer or anal canal cancer) in a person with hemorrhoids and rectal bleeding

Band ligation can be done as outpatient

External hemorrhoids will often recur

Table 24. Signs and Symptoms of Internal vs. External Hemorrhoids

Internal Hemorrhoids	External Hemorrhoids
Painless BRBPR	Sudden severe perianal pain
Rectal fullness or discomfort	Perianal mass
Mucus discharge	

Anal Fissures

Definition
- tear of anal canal below dentate line (very sensitive squamous epithelium)
- 90% posterior midline because posteromedial area is poorly perfused, 10% anterior midline
- if off midline: consider other possible causes such as IBD, STIs, TB, leukemia, or anal carcinoma
- repetitive injury cycle after first tear
  - sphincter spasm occurs preventing edges from healing and leads to further tearing
  - ischemia may ensue and contribute to chronicity

Etiology
- local trauma: constipation, irritation, diarrhea, vaginal delivery, anal intercourse
- secondary to: Crohn's disease, granulomatous diseases, malignancy, communicable diseases
- further tearing by internal anal sphincter spasm and hypertonicity

Clinical Features
- acute fissure
  - very painful bright red bleeding especially after bowel movement, sphincter spasm on limited DRE
  - treatment is conservative: stool softeners, bulking agents, and sitz baths (heals 90%)
- chronic fissure (anal ulcer)
  - triad: fissure, sentinel skin tags, and hypertrophied papillae
  - treatment
    - stool softeners, increased fibre intake, and sitz baths
    - topical nitroglycerin or calcium channel blocker (nifedipine or diltiazem): increases local blood flow, promotes healing, and relieves sphincter spasm
    - lateral internal anal sphincterotomy (most effective): relieves sphincter spasm to increase blood flow and promote healing; reserved for medically-refractory cases due to 5% chance of fecal incontinence
    - alternative treatment: botulinum toxin A; inhibits release of acetylcholine (ACh), reducing sphincter spasm

Prevention
- avoid diarrhea or constipation, avoid straining during defecation, high fibre diet, adequate fluids

Anorectal Abscess

Definition
- infection typically originating within an obstructed anal crypt which forms an abscess
- common bacterial: *E. coli, Proteus, Streptococci, Staphylococci, Bacteroides*, and anaerobes

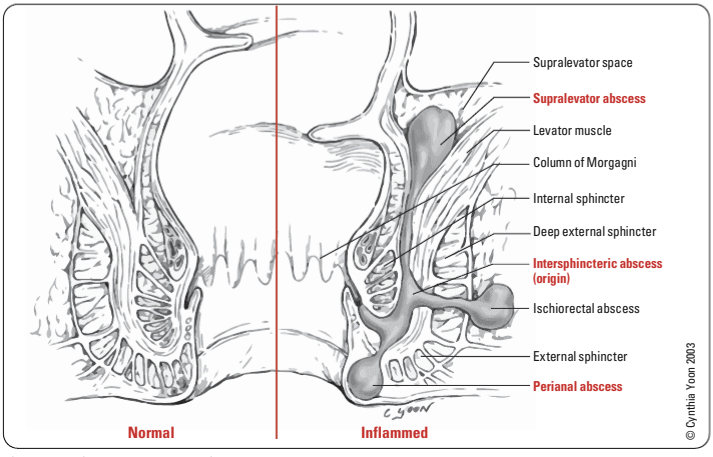

Figure 20. Different types of perianal abscesses

Clinical Features
- throbbing pain that may worsen with straining and ambulation
- abscess can spread vertically downward (perianal), vertically upward (supralevator), or horizontally (ischiorectal)
- tender perianal/rectal mass on exam

Treatment
- I&D
  - curative in 50% of cases
  - 50% develop anorectal fistulas
- may require antibiotics if patient has DM, a heart murmur, or cellulitis

Recurrent perianal abscesses is associated with Crohn's disease

Antibiotics are not typically helpful in the treatment of perianal abscesses

Fistula-In-Ano

Definition
- fistula from anal canal to perianal skin
- an inflammatory tract with internal os at dentate line, external os on skin

Etiology
- see *Fistula, GS46*
- same processes that lead to the formation of an anal abscess
- other causes: postoperative, trauma, anal fissure, malignancy, and radiation proctitis

Clinical Features
- intermittent or constant purulent discharge from perianal opening
- pain
- palpable cord-like tract
- inflamed or excoriated perianal skin
- MRI best imaging but can use CT or U/S depending on location

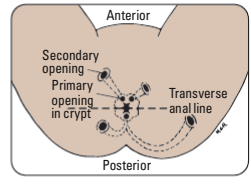

Figure 21. Goodsall's rule

Treatment
- identification
  - internal opening
    - Goodsall's rule: fistulas originating anterior to a transverse line through the anus will have a straight course and exit anteriorly, whereas those originating posterior to the transverse line will begin in the midline and have a curved tract
  - fistulous tract
    - probing or fistulography under anesthesia
- surgery
  - primary fistulotomy: unroof tract from external to internal opening, allows drainage, heals by secondary intention
    - best treatment for low lying fistula (does not involve external sphincter)
  - staged fistulotomy with Seton (rubber band or suture) placed through tract
    - used for high lying fistula (involves external sphincter)
    - promotes drainage, fibrosis, and decreases incidence of incontinence
    - delineates anatomy and usually done to spare muscle
  - ligation of intersphincteric fistula tract (LIFT) procedure
    - access fistula between sphincter muscles, sparing them
  - endoanal advancement flaps

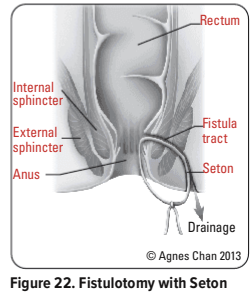

Figure 22. Fistulotomy with Seton suture

Postoperative
- sitz baths, irrigation, and packing to ensure healing proceeds from inside to outside

Complications
- recurrence
- rarely fecal incontinence

Pilonidal Disease

Definition
- pilo = hair, nidal = nest; cyst or abscess near or on the intergluteal cleft of the sacrococcygeal area containing hair and skin debris

Epidemiology
- occurs most frequently in young men ages 15-35; rare in >50 yr

Etiology
- obstruction of the hair follicles in this area → formation of cysts, sinuses, or abscesses
- associated with occupations that require prolonged sitting, obesity, and high amounts of body hair

Clinical Features
- asymptomatic or chronically itchy until acutely infected, then pain/tenderness, purulent discharge, and increased moisture near the tailbone

Treatment
- acute abscess
  - I&D (often performed by primary care physicians)
  - wound packed open
  - 40% develop chronic pilonidal sinuses
- surgery
  - indication: failure of healing after I&D, recurrent disease, or complex disease
  - pilonidal cystotomy: excision of sinus tract and cyst; wound closed by secondary intention (vac dressing), primary closure with tissue flap, or marsupialization (cyst edge sewn to surrounding tissue to leave sinus tract open)

Rectal Prolapse

Definition
- protrusion of some or all of rectal mucosa through external anal sphincter

Epidemiology
- extremes of ages: <5 yr and >50 yr
- 85% women

Etiology
- lengthened attachment of rectum secondary to constant straining
- 2 types
  1. false/partial/mucosal: protrusion of mucosa only, radial furrows at junction with anal skin; most common type of rectal prolapse in childhood
  2. true/complete (most common): full-thickness extrusion of rectal wall, concentric folds in:
     - 1st degree: prolapse includes mucocutaneous junction
     - 2nd degree: without involvement of mucocutaneous junction
     - 3rd degree (internal intussusception): prolapse is internal, concealed, or occult

Risk Factors
- gynecological surgery
- chronic neurologic/psychiatric disorders affecting motility e.g. chronic constipation
- multiparity
- weak pelvic floor

Clinical Features
- extrusion of mass with increased intra-abdominal pressure
- difficulty in bowel regulation
  - tenesmus, constipation, fecal incontinence
- permanently extruded rectum with excoriation, ulceration, and constant soiling
- may be associated with urinary incontinence or uterine prolapse
- pain is not common

Treatment
- type I
  - conservative: gentle manual reduction of prolapsed area, especially in children
  - mucosectomy with excision of redundant mucosa, mostly in adults
- type II
  - conservative: reduce if possible
  - surgery: abdominal, perineal, and trans-sacral approaches

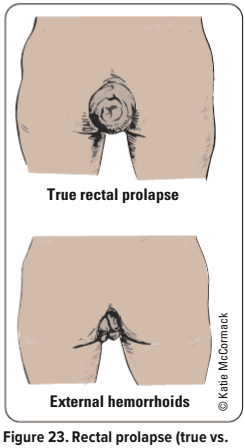

Figure 23. Rectal prolapse (true vs. false)

Anal Neoplasms

ANAL CANAL

Squamous Cell Carcinoma of Anal Canal (Distal to Dentate Line)
- most common tumour of anal canal (75%)
- anus prone to human papillomavirus (HPV) infection, therefore at risk for anal squamous intraepithelial lesions (ASIL)
  - high-grade squamous intraepithelial lesion (HSIL) and low-grade squamous intraepithelial lesion (LSIL) terminology used
- clinical features: anal bleeding, pain, mass, ulceration, and pruritus; 25% asymptomatic
- treatment: chemotherapy ± radiation ± surgery
- prognosis: 80% 5 yr survival

Malignant Melanoma of Anal Canal

- 3rd most common site for primary malignant melanoma after skin, eyes
- aggressive, distant metastases common at time of diagnosis
- occasionally an incidental finding in pathological evaluation of an anal specimen
- clinical features: bleeding, mass anorectal pain, change in bowel habits, pigmented in one third cases, regional lymph node involvement
- treatment: wide excision or APR ± chemoradiation
- prognosis: <5% 5 yr survival

ANAL MARGIN

- clinical features and treatment as for skin tumours elsewhere
- squamous and basal cell carcinoma, Bowen's disease (SCC in situ), and Paget's disease

Liver

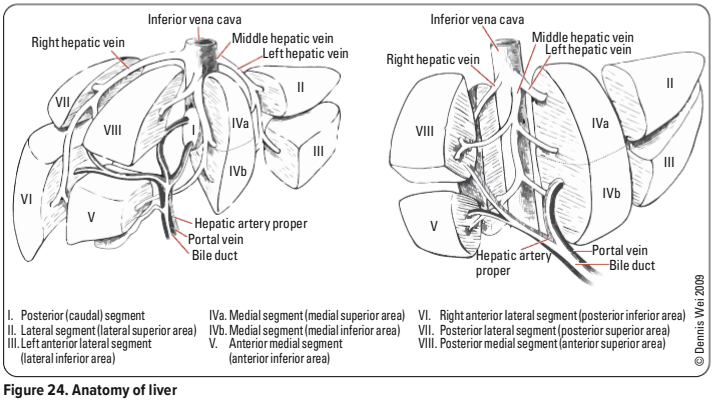

Figure 24. Anatomy of liver

Liver Cysts

Table 25. Characteristics of Liver Cysts

	Simple Cysts	Polycystic Liver Disease	Choledochal Cysts	Hydatid (Cystic Echinococcosis)	Cystadenoma (Premalignant)/ Cystadenocarcinoma
Description	Form from biliary ducts that do not communicate with the intrahepatic biliary tree and contain clear fluid Most common May have multiple cysts Always benign Examples include congenital cysts, Caroli disease, biliary hamartomas, and polycystic liver disease (PCLD)	Several (>20) cysts that replace much of the liver parenchyma Autosomal-dominant condition More common in females	Congenital malformations of the bile ducts High-risk of malignancy Majority present before age 10 Todani classification based on anatomical characteristics within biliary tree	Infection with parasite *Echinococcus granulosus* Associated with exposure to dogs, sheep, horses, pigs, goats, camels, and cattle in Southern Europe, Middle East, Australasia, South America Ingested parasitic eggs hatch in the small intestine, where larvae enter blood and lymph	Cystadenomas are rare cystic neoplasms arising from the bile ducts Cystadenoma is the most common premalignant liver lesion Cystadenocarcinoma is an invasive carcinoma
Clinical Features	Usually asymptomatic Mass effect can cause: dull RUQ pain, N/V, bloating, and/or early satiety	Minority present with acute complications due to cyst rupture, hemorrhage, infection, and compression of adjacent structures Progressive 50% associated with polycystic kidney disease (if over age 60)	Recurrent abdominal pain Intermittent jaundice RUQ mass Cholangitis Symptomatic gallstones Pancreatitis Portal HTN	Usually asymptomatic May have palpable RUQ mass or hepatomegaly Chronic RUQ pain when symptomatic Nausea, fever, and dyspepsia are non-specific symptoms	Upper abdominal mass Abdominal pain Anorexia
Investigations	Labs: some have elevated GGT, CEA, CA 19-9 U/S: Used for diagnosis and follow-up CT: well demarcated lesion that does not enhance with contrast	U/S: cysts are well circumscribed and nonenhancing MRI: more sensitive and specific, used for preoperative planning	Labs: LFT abnormalities U/S CT Transhepatic cholangiography ERCP MRCP	Labs: anti-Echinococcus ab U/S CT: calcified cystic walls Needle biopsy	Labs: cystadenocarcinoma may have elevated LFTs, CEA, or CA 19-9 U/S: anechoic mass with internal septations that are highly echogenic CT MRI MRCP ERCP Need histology for definite diagnosis

Table 25. Characteristics of Liver Cysts

	Simple Cysts	Polycystic Liver Disease	Choledochal Cysts	Hydatid (Cystic Echinococcosis)	Cystadenoma (Premalignant)/ Cystadenocarcinoma
Treatment	Not required unless very large and/or symptomatic Monitor if >4 cm Laparoscopic or open cyst wall removal (unroofing) is established treatment and is usually curative Percutaneous aspiration and ethanol sclerotherapy also an option, but not curative	Symptomatic patients: cyst aspiration with sclerosis, cyst fenestration, hepatic resection, transarterial embolization, and transplantation	Complete excision of cysts Liver resection or transplantation if cystic dilatation involves intrahepatic bile ducts (Caroli's disease)	Systemic chemotherapy: Albendazole (anti-helminthic drug) cure up to 30% Surgical: radical (total pericystectomy, partial hepatectomy, or lobectomy) vs. conservative (drainage or open/ closed cystectomy) Percutaneous: PAIR (puncture, aspiration, injection, re-aspiration)	All complex, multiloculated cysts (except echinococcal) should be excised because of malignancy risk
Complications	Hemorrhage, rupture, infection, and biliary obstruction more likely in larger cysts Intracystic hemorrhage is rare and presents with severe abdominal pain		Biliary cirrhosis, portal HTN, cyst rupture, or cholangiocarcinoma Increased risk of biliary malignancy	IVC compression Cyst rupture which can cause fever, pruritus, eosinophilia, biliary colic, jaundice, cholangitis, pancreatitis, or anaphylaxis	Cystadenocarcinoma can invade adjacent tissues and metastasize

Liver Abscesses

Etiology
- types
  - pyogenic (bacterial): most common etiology; most often polymicrobial – *Klebsiella, E. coli, Proteus, Streptococcus, Staphylococcus*, and anaerobes
  - parasitic (amoebic): *Entamoeba histolytica*, Echinococcal cyst
  - fungal: *Candida*
  - sources: direct spread from biliary tract infection, portal spread from GI infection, systemic infection (e.g. endocarditis)

Clinical Features
- fever, malaise, chills, anorexia, weight loss, abdominal pain, and nausea
- RUQ tenderness, hepatomegaly, and jaundice

Investigations
- CBC (leukocytosis, anemia), LFTs (elevated ALP and hypoalbuminemia common; elevated transaminases and bilirubin variable), blood cultures, INR/PTT, stool cultures, and serology (*E. histolytica* and *Echinococcus*)
- CT or U/S are the imaging modalities used for diagnosis with abscess drainage for C&S to confirm diagnosis; MRI can also be used.

Treatment
- treat underlying cause
- pyogenic abscesses generally treated with antibiotic therapy (e.g. ceftriaxone and metronidazole or piperacillin-tazobactam) and U/S- or CT-guided percutaneous drainage or surgical drainage
- consider potential source of sepsis (e.g. biliary source, infected tumour)

Prognosis
- overall mortality 15% – higher rate if delay in diagnosis, multiple abscesses, malnutrition, elderly, ICU admissions, shock, cancer, cirrhosis, chronic kidney disease (CKD), acute respiratory failure, and biliary origin of abscess

Neoplasms

BENIGN LIVER NEOPLASMS

Hemangioma (cavernous)
- pathogenesis: most common benign hepatic tumour; results from malformation and proliferation of vascular endothelial cells
- risk factors: M:F=3:1
- clinical features
  - usually small and asymptomatic, those greater than 10 cm are considered giant and may cause abdominal pain or discomfort
  - consumptive coagulopathy if giant (in children)
- investigations
  - contrast CT (well-demarcated hypodense mass with peripheral enhancement on arterial phase with centripetal filling on delayed phases), U/S (homogeneous hyperechoic mass), MRI
  - avoid biopsy: may result in hemorrhage

- treatment
  - none if asymptomatic
  - in symptomatic patients or those with hemangiomas large enough causing mass effect, surgical resection should be considered after other causes of pain are excluded
  - surgical resection options: liver resection, hepatic artery ligation, enucleation, and in severe cases liver transplantation.
  - non-surgical treatment: hepatic artery embolization and radiotherapy

Focal Nodular Hyperplasia

- pathogenesis: unclear, hyperplastic response to vascular anomaly leading to disorganized growth of hepatocytes and bile ducts
- risk factors: female, reproductive age
- clinical features: usually asymptomatic, rarely grows or bleeds, and no malignant potential
- investigations: central stellate scar surrounded by homogenous lesion on CT scan; MRI, biopsy may be required
- treatment: may be difficult to distinguish from adenoma/fibrolamellar HCC (malignant potential)
  - if confirmed to be FNH → no treatment required

Adenoma

- pathogenesis: benign abnormal growth of glandular epithelium
- risk factors: female, ages 20-50, estrogen (OCP, pregnancy), obesity, anabolic androgen use, and type 1 glycogen storage disease
- clinical features: asymptomatic, 25% present with RUQ pain or mass, may present with bleeding
- investigations: CT (well-demarcated masses, often heterogeneous enhancement on arterial phase, isodense on venous phase without washout of contrast), U/S, MRI, biopsy can be considered, with bleeding risk taken into account
- treatment
  - stop anabolic steroids or OCP
  - excise, especially if large (>5 cm), due to risk of transformation to HCC and spontaneous rupture/hemorrhage

MALIGNANT LIVER NEOPLASMS

Primary

- most commonly HCC and cholangiocarcinoma
- others include angiosarcoma, hepatoblastoma, and hemangioendothelioma
- risk factors
  - chronic liver inflammation: cirrhosis from any cause, chronic hepatitis B (inherently oncogenic) and hepatitis C, hemochromatosis, α1-antitrypsin deficiency, and non-alcoholic steatohepatitis
  - medications: OCPs (3x increased risk), steroids
  - smoking, alcohol, betel nuts chewing
  - chemical carcinogens: aflatoxin, microcystin, and vinyl chloride (associated with angiosarcoma)
- clinical features
  - RUQ discomfort and right shoulder pain
  - jaundice, weakness, weight loss, and ± fever (if central tumour necrosis)
  - hepatomegaly, bruit, and hepatic friction rub
  - ascites with blood (sudden intra-abdominal hemorrhage)
  - paraneoplastic syndromes: hypoglycemia, hypercalcemia, erythrocytosis, and watery diarrhea
  - metastasis: lung, intra-abdominal lymph nodes, bone, adrenal gland, brain, and peritoneal seeding
- investigations
  - INR and LFTs: AST, ALT, ALP, bilirubin, and albumin
  - elevated ALP, bilirubin, and α-fetoprotein (80% of patients)
  - U/S (poorly-defined margins with internal echoes), triphasic CT (enhancement on arterial phase and washout on portal venous phase), and MRI
- treatment
  - cirrhosis is a relative contraindication to tumour resection due to decreased hepatic reserve
  - surgical: resection (10% of patients have resectable tumours)
  - liver transplant; may use bridging therapy while awaiting transplant
    - absolute contraindications: extrahepatic disease and vascular invasion
    - relative contraindications: dependent on liver transplant protocol based on staging criteria followed by transplant centre
  - non-surgical: radiofrequency ablation, percutaneous ethanol injection, transcatheter arterial chemoembolization (TACE), chemotherapy (consider sorafenib for HCC; preoperative chemotherapy for hepatoblastoma is standard of care), and radiotherapy
- prognosis
  - 5 yr survival: 18% of all patients; 40-70% of patients undergoing complete resection

Liver Transplantation Criteria for Hepatocellular Carcinoma

Milan Criteria*	1 tumour ≤5 cm Up to 3 tumours each ≤3 cm
UCSF Criteria*	1 tumour ≤6.5 cm Up to 3 tumours each ≤4.5 cm, total diameter ≤8 cm
Toronto Criteria*	No tumour size or number restrictions No systemic symptoms Not poorly differentiated

*Each criteria assumes no extrahepatic and no macrovascular invasion

Child-Turcotte-Pugh Score (Prognosis of Chronic Liver Disease/Cirrhosis, including Postoperatively)

	1 Point	2 Points	3 Points
Albumin (g/L)	>35	28-35	<28
Ascites	Absent	Easily controlled	Poorly controlled
Bilirubin (μmol/L)	<34	34-51	>51
(mg/dL)	<2.0	2.0-3.0	>3.0
Coagulation (INR)	<1.7	1.7-2.3	>2.3
Hepatic Encephalopathy	None	Minimal	
(Grade I-II)	Advanced		
(Grade III-IV)			

Points	Class	One Yr Survival	Two Yr Survival
5-6	A	100%	85%
7-9	B	81%	57%
10-15	C	45%	35%

Secondary

- metastases to the liver are the most common malignant tumours found in the liver
- etiology
  - GI (colorectal most common), lung, breast, pancreas, GI NET, stomach, melanoma, ovary, uterus, kidney, gallbladder, and prostate
- treatment
  - depends on the primary cancer site and prognosis
    - often liver metastases are a manifestation of Stage IV disease and chemotherapy is indicated
  - metastasectomy may be appropriate for cancers either through surgical resection or local treatment (i.e. embolization)
    - hepatic resection of metastatic colorectal liver metastases is standard of care as part of multi-modality treatment that includes chemotherapy if complete resection of the primary cancer and metastases is possible
    - transplant also a new and emerging alternative for metastatic disease in the liver
- prognosis
  - following liver resection for colorectal metastases is an overall survival of 30-60% at 5 yr

Secondary liver metastases are common in many cancers, with some studies showing a prevalence of 40-50% amongst patients with extrahepatic cancers. They commonly arise from colorectal, lung, and breast cancers. For metastases secondary to colorectal cancer, surgical resection offers the greatest likelihood of cure

Liver Transplantation

Table 26. Conditions Leading to Transplantation

Parenchymal Disease	Cholestatic Disease	Inborn Errors	Tumours
Chronic hepatitis B or C*	Biliary atresia**	α1-antitrypsin deficiency	Hepatocellular carcinoma
Alcoholic cirrhosis	Primary biliary cirrhosis	Wilson's disease	Hepatoblastoma
Acute liver failure	Sclerosing cholangitis	Hemochromatosis	Metastatic NETs
Budd-Chiari syndrome			Colorectal cancer
Congenital hepatic fibrosis			
CF			
Autoimmune hepatitis			
Cryptogenic cirrhosis			
Drug induced hepatotoxicity			
Non-alcoholic steatohepatitis			

*leading cause in adults; **leading cause in children

Living Liver Donors vs. Deceased Liver Donors
The right lobe of a living donor liver is transplanted into the recipient. This is due to the larger right lobe providing a greater graft volume to sustain the metabolic demand of recipients. Donor safety and graft suitability for recipients should be considered in living donor liver transplants. Whole livers from deceased donors are transplanted orthotopically into the recipient

Clinical Indications

- early referral for transplant should be considered for all patients with progressive liver disease not responsive to medical therapy, especially:
  - decompensated cirrhosis (ascites, esophageal variceal hemorrhage, spontaneous hepatic encephalopathy, coagulopathy, progressive jaundice, severe fatigue)
  - unresectable primary liver cancers
  - unresectable but localized liver metastasis of colorectal cancer - new emerging indication
  - acute liver failure
  - liver-based metabolic conditions including α-1-antitrypsin deficiency
- end-stage liver disease with life expectancy <1 yr and if no other therapy is appropriate
  - suitable HCC not amenable to liver resection

Criteria for Transplantation

- Model for End-Stage Liver Disease (MELD): prognostic model to estimate 3 mo survival following transjugular intrahepatic portosystemic shunt (TIPS) procedure and to prioritize patients awaiting liver transplant; based on creatinine, bilirubin, INR, sodium (MELD-Na), female sex, and serum albumin; MELD scores used to prioritize liver allocation
- Child-Turcotte-Pugh Score: classification system to assess the prognosis and the abdominal surgery perioperative mortality of chronic liver disease and cirrhosis; patient must have ≥7 points (Class B) for transplant evaluation

Contraindications

- active alcohol/substance use
- extrahepatic malignancy within 5 yr
- advanced cardiopulmonary disease
- active uncontrolled infection

Postoperative Complications

- primary non-function (graft failure): urgent re-transplantation is indicated
- acute and chronic rejection, ischemia-reperfusion injury
- vascular: hepatic artery or portal vein thrombosis, IVC obstruction
- biliary complications: fever, increasing bilirubin and ALP
- complications related to immunosuppression: HTN, renal disease, DM, obesity, hyperlipidemia, osteoporosis, malignancy, neurologic complications, infection (leading cause of mortality following transplant)

Prognosis

- patient survival at 1 yr: 85%
- graft survival at 1 yr: >80%, at 5 yr: 60-70%

Biliary Tract

Cholelithiasis

Definition
- the presence of stones in the gallbladder

Pathogenesis
- imbalance of cholesterol and its solubilizing agents (bile salts and lecithin)
- excess hepatic cholesterol secretion relative to bile salts and lecithin → supersaturated cholesterol which precipitates as gallstones
- North America: cholesterol stones (80%), pigment stones (20%)

Risk Factors
- cholesterol stones
  - obesity
  - increasing age
  - prevalence higher in females (especially females <50 yr)
  - estrogens: female, multiparity, OCPs
  - impaired gallbladder emptying: starvation, TPN, DM
  - rapid weight loss: rapid cholesterol mobilization and biliary stasis
- pigment stones (contain calcium bilirubinate)
  - cirrhosis
  - chronic hemolysis
  - biliary stasis (strictures, dilation, biliary infection)
  - terminal ileal resection or disease (e.g. Crohn's disease)
- protective factors
  - statins, physical activity, vitamin C, poly- and monounsaturated fats and nuts, coffee

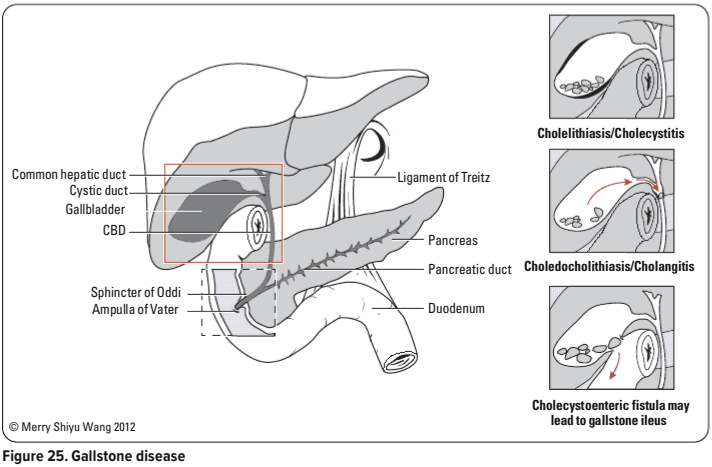

Figure 25. Gallstone disease

Clinical Features
- asymptomatic (80%): found incidentally
  - 18% risk of progression to symptomatic gallstone disease within 20 yr
  - most do NOT require treatment
  - consider cholecystectomy if: increased risk of malignancy (choledochal cysts, Caroli's disease, porcelain or calcified gallbladder), sickle cell disease, paediatric patient, bariatric surgery, or immunosuppression
- biliary colic (10-25%)

Investigations
- normal bloodwork: CBC, electrolytes, Cr, LFTs, bilirubin, lipase
- U/S: diagnostic procedure of choice
  - image for signs of inflammation, obstruction, and localization of stones
  - 95% specific for detecting stones

Risk Factors for Cholesterol Stones

4Fs
Fat
Female
Fertile
Forties

Summary of Biliary Tract Conditions

Gallbladder	Asymptomatic	Pain Only	Infection + Pain
Cholelithiasis	✓ (majority)		
Biliary Colic		✓	
Cholecystitis			✓
Common Bile Duct	**Asymptomatic**	**Pain Only**	**Infection + Pain**
Choledocholithiasis	✓ (majority)	✓	
Cholangitis			✓ (majority)

Biliary Colic

Pathogenesis
- gallstone transiently impacted in cystic duct, no infection

Clinical Features
- an episode of steady, severe dull pain in the epigastrium or RUQ lasting minutes to hours (<6 h), crescendo-decrescendo pattern
- can present with chest pain, right shoulder tip pain, scapular pain
- N/V
- frequently occurs at night or after fatty meal, not after fasting
- no peritoneal findings, no systemic signs

Investigations
- normal blood work: CBC, electrolytes, Cr, LFTs, bilirubin, lipase
- U/S shows cholelithiasis, may show stone in cystic duct (neck of gallbladder)

Treatment
- analgesia, rehydration during colic episode
- elective cholecystectomy (95% success)
  - complications: CBD injury (0.3-0.5%), hollow viscus injury, bile peritonitis, and vessel injury leading to liver damage
  - laparoscopic cholecystectomy is the standard of care, no benefit to delaying surgery

Acute Cholecystitis

Pathogenesis
- inflammation of gallbladder resulting from sustained gallstone impaction in cystic duct or Hartmann's pouch
- no cholelithiasis in 5-10% (see *Acalculous Cholecystitis, GS57*)

Clinical Features
- often have history of biliary colic
- severe constant (>6 h) epigastric or RUQ pain, anorexia, N/V, and low grade fever (<38.5°C)
- focal peritoneal findings: Murphy's sign, palpable and tender gallbladder (in 33%)
- Boas' sign: right subscapular pain

Investigations
- blood work: elevated WBC and left shift, mildly elevated bilirubin concerning for bile duct obstruction (either stones or Mirizzi syndrome)
- U/S: 98% sensitive, consider HIDA scan if U/S negative
  - signs: gallbladder wall thickening >4 mm, edema (double-wall sign), gallbladder sludge, cholelithiasis, pericholecystic fluid, and sonographic Murphy's sign

Complications
- gangrenous gallbladder (20%) most common complication
- perforation (10%): result in abscess formation or rarely local peritonitis
- Mirizzi syndrome: extra-luminal compression of CBD/CHD due to large stone in cystic duct
- empyema of gallbladder: suppurative cholecystitis (pus in gallbladder) and sick patient
- emphysematous cholecystitis: bacterial gas present in gallbladder lumen, wall, or pericholecystic space (risk in diabetic patient); organisms involved in secondary infection: *C. welchii, E. coli, Klebsiella*, anaerobic streptococci, Enterococcus
- cholecystoenteric fistula (from repeated attacks of cholecystitis) can lead to gallstone ileus

Treatment
- admit, hydrate, NPO, NG tube (if persistent vomiting from associated ileus), analgesics
- antibiotics
  - cefazolin if uncomplicated cholecystitis
- ERCP prior to surgery if CBD stones are present on U/S
  - MRCP ± ERCP if CBD is markedly dilated or CBD stones suspected
- cholecystectomy
  - early (within 72 h) vs. delayed (after 6 wk, not standard)
  - equal morbidity and mortality
  - early cholecystectomy preferred: shorter hospitalization and recovery time, no benefit to delaying surgery
  - emergent OR indicated if high-risk, e.g. sepsis
  - laparoscopic is standard of care (convert to open for complications or difficult case)
    - reduced risk of wound infections, shorter hospital stay, reduced postoperative pain, and increased risk of bile duct injury
- intraoperative cholangiography (IOC)
  - indications: clarify bile duct anatomy, history of biliary pancreatitis, small stones in gallbladder with a wide cystic duct (>15 mm), and jaundice
  - has been mostly replaced by preoperative MRCP

Biliary colic is a pain that comes and goes, but cholecystitis is a pain which is constant and usually increasing

2 Most Important Lab Tests for Biliary Pain

Lipase: to determine if element of pancreatitis

Bilirubin: to determine if bile duct obstruction

Biliary colic is treated with analgesia and elective cholecystectomy
Acute cholecystitis is treated with antibiotics and early cholecystectomy if surgical risk appropriate

Toronto Video Atlas of Surgery: Standard Laparoscopic Cholecystectomy
TVAsurg is an open access library of animation enhanced surgical videos created by surgeons in Toronto. For a video simulation of a standard laparoscopic cholecystectomy, see http://pie.med.utoronto.ca/TVASurg/project/standardlapchole/

Mirizzi Syndrome
Extrinsic compression of the CHD by a gallstone in the cystic duct or Hartmann's pouch. Impacted gallstone may erode into the CHD or CBD, creating a cholecystohepatic or cholecystocholedochal fistula; Mirizzi syndrome has an association with gallbladder cancer

Rouviere's Sulcus
Fissure between right lobe and caudate process (segment I) of liver; keeping dissection anterior to this landmark can minimize bile duct injury

Critical View of Safety (CVS)
Decreases risk of injury to CBD during laparoscopic cholecystectomy, 3 criteria are required to achieve the CVS:
1. The hepatocystic triangle (formed by the cystic duct, CHD, and inferior edge of the liver) is cleared of fat and fibrous tissue
2. The lower one third of the gallbladder is separated from the liver to expose the cystic plate
3. Two and only two structures should be seen entering the gallbladder (cystic duct and artery)

- percutaneous cholecystostomy tube: critically ill or if general anesthetic contraindicated
- some centres can perform percutaneous stone extraction to avoid cholecystectomy or create fistulas from stomach to gallbladder to decompress and create an internal cholecystostomy tube without the morbidity of percutaneous tube

Early vs. Delayed Laparoscopic Cholecystectomy for Acute Cholecystitis: A Meta-Analysis of Randomized Clinical Trials
Am J Surg 2008;196(1):40-47
Purpose: Evaluate effects of early versus late laparoscopic cholecystectomy in treatment of acute cholecystitis.
Methods: Systematic review and meta-analysis of randomized studies in Medline, Embase, Cochrane, and Google Scholar between 1987-2006. Endpoints included rates of conversion to open surgery, postoperative complications, length of stay, and duration of surgery.
Results: 4 RCTs included with a total of 375 patients. No differences were found between early and late groups in rates of conversion to open surgery (P=0.718) or postoperative complications (P=0.813). Length of stay was shorter for the early group (P= 0.0005) while duration of surgery was shorter for the late group (P=0.002).
Conclusions: Early laparoscopic cholecystectomy for acute cholecystitis reduces length of hospital stay with comparable rates of conversion to open surgery and postoperative complications compared with late surgery.

Acalculous Cholecystitis

Definition
- acute or chronic cholecystitis in the absence of stones

Pathogenesis
- typically due to gallbladder ischemia and stasis

Risk Factors
- ICU admission (most common), DM, immunosuppression, trauma patient, TPN, and sepsis

Clinical Features
- see *Acute Cholecystitis, GS56*
- occurs in 10% of cases of acute cholecystitis

Investigations
- bloodwork: CBC, electrolytes, Cr, LFTs, liver enzymes, bilirubin, and lipase
- U/S: shows sludge in gallbladder, other U/S features of cholecystitis (see *Acute Cholecystitis, GS56*)
- CT or HIDA scan

Treatment
- NPO, IV fluids, and pain management
- IV broad-spectrum antibiotics, cholecystectomy
- if patient unstable → percutaneous cholecystostomy

Choledocholithiasis

Definition
- stones in CBD

Clinical Features
- often have history of biliary colic
- tenderness in RUQ or epigastrium
- acholic stool, dark urine, and fluctuating jaundice
- primary vs. secondary stones
  - primary: formed in bile duct, indicates bile duct pathology (e.g. benign biliary stricture, sclerosing cholangitis, choledochal cyst, and CF)
  - secondary: formed in gallbladder (85% of cases in the U.S.)

American Society of Gastrointestinal Endoscopy 2019 Guideline on Role of Endoscopy in Evaluating Choledocolithiasis

Proceed directly to ERCP
- CBD stone on U/S
- Clinical ascending cholangitis
- Bilirubin >4 mg/dL (>347 umol/L) & dilated CBD on U/S

Perform U/S, MRCP, Laparoscopic IOC or Intraoperative US
- Abnormal liver tests
- Age >55 yr
- Dilated CBD on U/S

Investigations
- CBC: usually normal; leukocytosis suggests cholangitis
- LFTs: increased AST, ALT early in disease, increased bilirubin (more sensitive), ALP, GGT later
- lipase: to rule out gallstone pancreatitis
- U/S: intra-/extra-hepatic duct dilatation; differential diagnosis is choledochal cyst
- MRCP (90% sensitive)
  - visualization of ampullary region, biliary, and pancreatic anatomy
  - non-invasive diagnostic test of choice
- ERCP
  - CBD stones in periampullary region
  - diagnostic and therapeutic; removal of stones and sphincterotomy possible
  - complications: retained stones, ERCP pancreatitis (1-2%), pancreatic or biliary sepsis
- Percutaneous Transhepatic Cholangiography
  - percutaneous approach to the proximal biliary tree (i.e. intrahepatic biliary system) via the hepatic parenchyma
  - useful for proximal bile duct obstruction or when ERCP fails or not available
  - contraindications: ascites, peri/intrahepatic sepsis, and disease of right lower lung or pleura
  - complications: bile peritonitis, chylothorax, pneumothorax, biliary sepsis, and hemobilia
- Intraoperative Cholangiography (IOC)
  - intraoperative injection of radiographic contrast into the cystic duct to evaluate CBD during laparoscopic cholecystectomy
  - useful for identifying CBD stones, clarifying biliary anatomy, and preventing CBD injury during cholecystectomy

Complications
- cholangitis, pancreatitis, biliary stricture, and biliary cirrhosis

Treatment
- treat with ERCP for CBD stone extraction possibly followed by elective cholecystectomy in 25% of patients
- biliary tree flushing with laparoscopic cholecystectomy:
  - during a laparoscopic cholecystectomy ± cholangiogram, the cystic duct can be flushed to the CBD with the use of glucagon to relax the sphincter between the CBD and duodenum. Can also use cholangiogram to confirm stones flushed into duodenum

Acute Cholangitis

Pathogenesis
- obstruction of CBD leading to biliary stasis, bacterial overgrowth, suppuration, and biliary sepsis – may be life-threatening, especially in elderly

Etiology
- choledocholithiasis (60%), stricture, neoplasm (pancreatic or biliary), extrinsic compression (pancreatic pseudocyst or pancreatitis), instrumentation of bile ducts (PTC, ERCP), and biliary stent
- organisms: *E. coli, Klebsiella, Enterobacter, Pseudomonas, Enterococcus, B. fragilis*, and *Proteus*

Clinical Features
- Charcot's triad: fever, RUQ pain, and jaundice
- Reynold's pentad: Charcot's triad, hypotension, and altered mental status
- may have N/V, abdominal distention, ileus, acholic stools, and tea-coloured urine (elevated direct bilirubin)

Charcot's Triad
Fever, RUQ pain, jaundice

Reynolds' Pentad
Fever, RUQ pain, jaundice, shock, and altered mental status

Investigations
- CBC: elevated WBC + left shift
- may have positive blood cultures
- LFTs: obstructive picture (elevated ALP, GGT, and conjugated bilirubin, possible mild increase in AST, ALT)
- lipase: rule out pancreatitis
- U/S: intra-/extra-hepatic duct dilatation
- CT: bile duct dilatation and can identify biliary stenosis
- MRCP when diagnosis is unclear

Common Bacteria in Biliary Tract

KEEPS
K*lebsiella*
E*nterococcus*
E*. coli, Enterobacter*
P*roteus, Pseudomonas*
S*erratia*

Treatment
- initial: NPO, fluid and electrolyte resuscitation, ± NG tube, IV antibiotics (treats 80%)
- biliary decompression
  - ERCP + sphincterotomy: diagnostic and therapeutic
  - PTC with catheter drainage: if ERCP not available or unsuccessful
  - open or laparoscopic CBD exploration and T-tube placement if above fails
- in addition to biliary decompression, the underlying cause should be addressed. In the case of patients with choledocholithiasis, elective cholecystectomy is recommended after resolution of acute cholangitis to prevent re-occurrence

Prognosis
- suppurative cholangitis mortality rate: 20-30%

Gallstone Ileus

Pathogenesis
- repeated inflammation causes a cholecystoenteric fistula (usually duodenal) → large gallstone enters the GI tract (impacting near the ileocecal valve) causing a mechanical bowel obstruction (note: ileus is a misnomer in this context)

Rigler's Triad of Gallstone Ileus
Pneumobilia
Small bowel obstruction
Gallstone

Clinical Features
- crampy abdominal pain, N/V, constipation/obstipation (see *Large Bowel Obstruction, GS37*)

Investigations
- AXR: dilated small intestine, air fluid levels, may reveal radiopaque gallstone, and air in biliary tree (pneumobilia) (40%)
- CT: biliary tract air, obstruction, and gallstone in intestine
- Rigler's triad: pneumobilia, SBO (partial or complete), and gallstone (usually in right iliac fossa)

Bouveret's Syndrome
Gastric outlet/duodenal obstruction caused by a large gallstone passing through a cholecystogastric or cholecystoduodenal fistula

Treatment
- fluid resuscitation, NG tube decompression
- surgery: enterolithotomy and removal of stone, inspect small and large bowel for additional proximal stones
- may close fistula surgically or manage expectantly (can resolve spontaneously)
- cholecystectomy is generally not performed

Carcinoma of the Gallbladder

Risk Factors
- chronic symptomatic gallstones (70% of cases), old age, female, gallbladder polyps, porcelain gallbladder, chronic infection (Salmonella, Helicobacter), primary sclerosing cholangitis, and abnormal pancreaticobiliary duct junction

Clinical Features
- majority are adenocarcinoma
- may be incidental finding on elective cholecystectomy (~1% of open cholecystectomies OR 0.1% in laparoscopic cholecystectomies)
- many patients are asymptomatic until late
- local: non-specific RUQ pain ± palpable RUQ mass
- Courvoisier's gallbladder sign: enlarged gallbladder and painless jaundice due to obstruction of CBD, suggestive of gallbladder or pancreatic malignancy
- systemic: jaundice (50%) due to invasion of CBD or compression of CBD by pericholedochal nodes, anorexia, N/V, weight loss, and malaise
- early local extension to liver, peritoneum, may extend to stomach, duodenum
- early metastasis common to lung, pleura, liver, bone

Investigations
- U/S: mural thickening, calcification, loss of interface between gallbladder and liver, and fixed mass
- endoscopic U/S (EUS): good for distinguishing carcinomas from other diagnoses such as, polyps, staging, allows sampling of bile for cytology
- abdominal CT: polypoid mass, mural thickening, liver invasion, nodal involvement, and distant metastases
- MRI/MRCP: good for distinguishing benign and malignant polyps

Treatment
- if carcinoma of the gallbladder is suspected preoperatively, an open cholecystectomy should be considered to avoid tumour seeding of the peritoneal cavity
- confined to mucosa (rare): cholecystectomy
- beyond mucosa: cholecystectomy, en bloc wedge resection of 3-5 cm underlying liver, and dissection of hepatoduodenal lymph nodes

Prognosis
- poor 5 yr survival (20%) as gallbladder carcinoma is often detected late
- better outcomes when detected incidentally following cholecystectomy

Cholangiocarcinoma

Definition
- malignancy of the epithelial cells of extra- or intrahepatic bile ducts

Risk Factors
- ages 50-70, gallstones, UC, primary sclerosing cholangitis, choledochal cyst, Clonorchis sinensis infection (liver fluke), chronic intrahepatic stones (hepatolithiasis), genetic disorders (Lynch syndrome, CF, multiple biliary papillomatosis, BAP1 tumour predisposition syndrome)

Clinical Features
- majority are adenocarcinomas
- gradual signs of biliary obstruction: jaundice, pruritus, dark urine, and pale stools
- anorexia, weight loss, RUQ pain, Courvoisier's sign (if CBD obstructed), hepatomegaly
- early metastases are uncommon, but commonly tumour grows into portal vein or hepatic artery, peritoneum, lungs, pleura, liver
- Klatskin tumour: cholangiocarcinoma located at bifurcation of CHD

Obstructive jaundice is the most common presenting symptom for cholangiocarcinoma

Investigations
- LFTs show obstructive picture, carbohydrate antigen 19-9 (CA 19-9), CEA may be elevated
- U/S, CT: bile ducts usually dilated, but not necessarily
- ERCP or PTC: to determine resectability, for biopsies
- CXR, bone scan: for metastatic workup

Treatment
- if resectable: biliary drainage and wide excision margin
- intrahepatic lesions: liver resection after clear discussion at multidisciplinary tumour boards and prognosis understood
  - upper third lesions: duct resection + Roux-en-Y hepaticojejunostomy, ± liver resection
  - middle third lesions (uncommon): duct resection + Roux-en-Y hepaticojejunostomy
  - lower third lesions: Whipple procedure

- unresectable lesions: stent or choledochojejunostomy (surgical bypass)
- chemotherapy ± radiotherapy
- role for transplantation in select patients with Klatskin tumours or NET with no evidence of extrahepatic disease and relative stability

Prognosis
- overall 5 yr survival: localized 30%, regional 24%, distant 2%

Pancreas

Acute Pancreatitis

- see Gastroenterology, G48

GALLSTONE PANCREATITIS (45% of Acute Pancreatitis)

Pathogenesis
- obstruction of pancreatic duct by large or small gallstones and biliary sludge
- backup of pancreatic enzymes can cause autodigestion of the pancreas

Clinical Features (Pancreatitis of Any Etiology)
- pain (epigastric pain radiating to back), N/V, ileus, peritoneal signs, jaundice, and fever
- Inglefinger's sign: pain worse when supine, and better when sitting forward
- may have coexistent cholangitis or pancreatic necrosis
- Ranson's criteria for determining prognosis of acute pancreatitis (see sidebar)
  - APACHE II score for determining prognosis of severe acute pancreatitis
- physical exam may show tachypnea, tachycardia, hypotension, abdominal distention and tenderness, Cullen's sign, and Grey Turner's sign

Investigations
- lipase (most sensitive and specific), elevated amylase (higher than alcoholic pancreatitis), and leukocytosis
- elevated ALT (>150 IU/L), AST strongly suggest gallstone etiology of pancreatitis
- U/S may show multiple stones (may have passed spontaneously), and edematous pancreas
- CXR, AXR, and CT (if severe to evaluate for complications)

Treatment
- supportive: e.g. NPO, hydration, analgesia, and early enteral nutrition
- antibiotics are not indicated for initial diagnosis. This is reserved for clear signs of infection on imaging
- stone often passes spontaneously (~90%); usually no surgical management in uncomplicated acute pancreatitis
- cholecystectomy during same admission (25-60% recurrence if no surgery)
- may need urgent ERCP + sphincterotomy if CBD stone impacted or cholangitis
- surgical indications in acute pancreatitis (rare):
  - drain placement and debridement for necrotizing pancreatitis if refractory to medical management, if septic, or in ICU without other sources of sepsis

Complications
- local complications
  - acute fluid collections
  - walled-off pancreatic fluid collection/pseudocyst (>4 wk)
  - abscess/infection, necrosis
- systemic complications
  - splenic/mesenteric/portal vessel thrombosis
  - pancreatic ascites/pancreatic pleural effusion
  - DM (due to pancreatic & insulin insufficiency)
  - ARDS/sepsis/multiorgan failure
  - coagulopathy/DIC
  - severe hypocalcemia

Ranson's Criteria
A. At admission
1. Ages >55 yr
2. WBC >16 x 10^9/L
3. Glucose >11 mmol/L
4. LDH ≥350 IU/L
5. AST >250 IU/L

B. During initial 48 h
1. Hct drop >10%
2. BUN rise >1.8 mmol/L
3. Arterial PO_2 <60 mmHg
4. Base deficit >4 mmol/L
5. Calcium <2 mmol/L
6. Fluid sequestration >6 L

C. Interpretation
<3 = severe pancreatitis unlikely (2% mortality)
≥3 = high mortality (≥15%)

Chronic Pancreatitis

- see Gastroenterology, G50

Surgical Treatment
- treatment is generally medical
- indications for surgery
  - failure of medical treatment
  - debilitating abdominal pain
  - pseudocyst complications: persistence, hemorrhage, infection, and rupture
  - CBD obstruction (e.g. strictures) and duodenal obstruction
  - pancreatic fistula, variceal hemorrhage secondary to splenic vein obstruction
  - rule out pancreatic cancer (present in 15% of chronic pancreatitis treated surgically)
  - anatomical abnormality causing recurrent pancreatitis
- preoperative CT and/or ERCP are mandatory to delineate anatomy
- minimally invasive options
  - endoscopic pancreatic duct decompression: less effective than surgery
  - extracorporeal shockwave lithotripsy: if pancreatic duct stones
  - celiac plexus block: lasting benefit in 30% patients, less effective in those <45 yr or with prior pancreatic surgery
- surgical options
  - drainage procedures: only effective if ductal system is dilated
  - Puestow procedure (lateral pancreaticojejunostomy): improves pain in 80% of patients
  - pancreatectomy: best option in absence of dilated duct
  - Whipple procedure (pancreaticoduodenectomy): proximal disease
  - distal pancreatectomy ± Roux-en-Y pancreaticojejunostomy: distal disease
  - total pancreatectomy: refractory disease
- islet cells autotransplantation can be used to control insulin-related morbidity
  - denervation of celiac ganglion and splanchnic nerves

WALLED-OFF PANCREATIC FLUID COLLECTIONS (PSEUDOCYSTS)
- localized fluid collections rich in pancreatic enzymes, with a non-epithelialized wall consisting of fibrous and granulation tissue
- complication of chronic and/or acute pancreatitis
- up to 40% resolve spontaneously
- cyst wall must be mature prior to drainage (4-6 wk)
- pseudoaneurysm an absolute contraindication to endoscopic drainage, must embolize first

Pseudocyst Management
- if asymptomatic: expectant management
- if symptomatic: choice of drainage procedure depends on location of fluid collection
  - endoscopic drainage: transmural vs. transpapillary (pseudoaneurysm an absolute contraindication, must embolize first)
  - surgical drainage: cystogastrostomy vs. cystoduodenostomy vs. cystojejunostomy
  - percutaneous catheter drainage
  - resection
  - if draining, attempt to biopsy cyst wall to rule out cystadenocarcinoma

The hallmark of chronic pancreatitis is epigastric pain radiating to the back

Total Pancreatectomy and Islet Autotransplantation: A Decade Nationwide Analysis
World J Transplant 2016;6(1):233-238
Purpose: To investigate outcomes and predictors of in-hospital morbidity and mortality after total pancreatectomy (TP) and islet autotransplantation.
Results: A total of 923 patients underwent IAT after pancreatectomy during 2002-2012. The most common indication of surgery was chronic pancreatitis (86%) followed by acute pancreatitis (12%). Overall mortality and morbidity of patients were 0% and 57.8 %, respectively. Postoperative hypoinsulinemia was reported in 42.3% of patients, indicating that 57.7% of patients were insulin independent during hospitalization. Predictors of in-hospital morbidity were obesity, fluid and electrolyte disorders, alcohol use, and weight loss.
Conclusion: Total pancreatectomy + islet autotransplantation is a safe procedure with no mortality, acceptable morbidity, and achieved high rate of early insulin independence. Obesity is the most significant predictor of in-hospital morbidity.

Pancreatic Cancer

Epidemiology
- 4th most common cause of cancer-related mortality in both men and women in Canada
- M:F=1.3:1, average ages: 50-70

Risk Factors
- increased age
- smoking: 2-5x increased risk, most clearly established risk factor
- high fat/low fibre diets
- heavy alcohol use
- obesity
- DM, chronic pancreatitis
- partial gastrectomy
- cholecystectomy
- chemicals: β-naphthylamine, benzidine
- African descent

Clinical Features
- the most common presenting symptoms are abdominal pain, jaundice, and weight loss
- head of the pancreas (70%)
  - pancreatic head tumours typically present with jaundice, steatorrhea, and weight loss
  - other features include anorexia, dark urine, hepatomegaly, cachexia, Courvoisier's sign, recent onset DM
- body or tail of pancreas (30%)
  - tends to present later and usually inoperable (80% are unresectable at diagnosis)
  - weight loss, vague mid-epigastric pain
  - <10% jaundiced

Investigations
- serum chemistry is non-specific, LFTs may show obstructive jaundice (elevated ALP and bilirubin)
- CA 19-9 most useful serum marker of pancreatic cancer
- U/S, CT (also evaluates metastasis and resectability) ± ERCP, MRI, EUS

Pathology
- ductal adenocarcinoma: most common type (75-80%); exocrine pancreas
- intraductal papillary mucinous neoplasm (IPMN)
- other: pancreatic NETs (non-functional, insulinoma, gastrinoma, VIPoma, glucagonoma, somatostatinoma), mucinous cystic neoplasm (MCN), acinar cell carcinoma
- see *Surgical Endocrinology, GS72* for functional pancreatic NETs

Treatment
- resectable (10-20% of pancreatic cancer)
  - no involvement of liver, peritoneum, or vasculature (hepatic artery, SMA, SMV, portal vein, IVC, aorta), no distant metastasis
  - Whipple procedure (pancreaticoduodenectomy) for cure <5% mortality
  - distal pancreatectomy ± splenectomy, lymphadenectomy if carcinoma of midbody and tail of pancreas
  - adjuvant chemotherapy recommended (gemcitabine ± capecitabine, 5-FU/leucovorin)
- locally advanced, borderline resectable
  - tumours that abut the SMA, SMV, portal vein, hepatic artery, or celiac artery
- locally advanced, non-resectable (palliative → relieve pain, obstruction)
  - encasement of major vascular structures including arteries
  - most body/tail tumours are not resectable (due to late presentation)
  - relieve biliary/duodenal obstruction with endoscopic stenting or double bypass procedure (choledochoenterostomy + gastroenterostomy)
  - palliative chemotherapy (gemcitabine + nab-paclitaxel, FOLFIRINOX) ± radiotherapy

Prognosis
- most important poor prognostic indicators are lymph node status, margin status, size >3 cm, perineural invasion (invasion of tumour into microscopic nerves of pancreas)
- overall 5 yr survival for all patients with pancreas cancer is 1%; following surgical resection 5 yr survival is 20%
- median survival for unresectable disease: 3-6 mo if metastatic, 8-12 mo if locally advanced at presentation

Table 27. TNM Classification System for Exocrine Tumours of the Pancreas (AJCC 8th edition)

Primary Tumour (T)		Regional Lymph Nodes (N)		Distant Metastasis (M)	
TX	Primary tumour cannot be assessed	NX	Regional lymph nodes cannot be assessed	M0	No distant metastasis
T0	No evidence of primary tumour	N0	No regional lymph node metastasis	M1	Distant metastasis
Tis	Carcinoma *in situ*	N1	Metastasis in one to three regional lymph nodes		
T1	Tumour ≤2 cm in greatest dimension				
N2	Metastasis in four or more regional lymph nodes				
T2	Tumour >2 cm and ≤4 cm in greatest dimension				
T3	Tumour >4 cm in greatest dimension				
T4	Tumour involves celiac axis, SMA, or common hepatic artery				

Trousseau's Sign
Spontaneous peripheral venous thrombosis, often associated with pancreatic and other cancers

Vague abdominal pain with weight loss ± jaundice in a patient over 50 yr is pancreatic cancer until proven otherwise

Courvoisier's Sign
Palpable, nontender, distended gallbladder due to CBD obstruction. Present in 33% of patients with pancreatic carcinoma. The distended gallbladder could not be due to acute cholecystitis or stone disease because the gallbladder would actually be scarred and smaller, not larger

Steps of a Whipple Resection (Pancreaticoduodenectomy)
1. Assessment of metastatic disease (all peritoneal surfaces)
2. Mobilization of the hepatic flexure of the colon
3. Mobilization of the duodenum (Kocher maneuver) and head of the pancreas
4. Identification of the superior mesenteric vein and mobilization of the pancreatic neck
5. Mobilization of the stomach; dissection of the hepatoduodenal ligament and cholecystectomy
6. Division of the stomach, proximal jejunum, and CBD
7. Transection of the pancreatic neck and dissection of the uncinate process from the retroperitoneum
8. Restoration of gastrointestinal continuity: construction of a pancreaticojejunostomy, hepaticojejunostomy, gastrojejunostomy using a neoduodenum

Remove
- CBD
- Gallbladder
- Duodenum
- Pancreatic head
- Distal stomach (sometimes)

Oncological Benefits of Neoadjuvant Chemoradiation with Gemcitabine vs. Upfront Surgery in Patients with Borderline Resectable Pancreatic Cancer: A Prospective, Randomized, Open-label, Multicenter Phase 2/3 Trial
Ann Surg 2018;268:215-222
Purpose: To determine whether neoadjuvant treatment increases survival in patients with borderline resectable pancreatic cancer (BRPC).
Methods: A total of 50 patients were randomized to neoadjuvant gemcitabine-based chemoradiotherapy or upfront surgery.
Results: The 2-yr survival rate (2YSR) and median survival of patients treated with neoadjuvant chemoradiation was significantly improved (40.7% 2YSR, 21 mo median survival) compared to upfront surgery (26.1% 2YSR, 12 mo median survival). The R0 resection rate was also significantly increased in the neoadjuvant chemoradiation group.
Conclusion: Neoadjuvant chemoradiation provides survival and surgical benefits in patients with BRPC.

Table 28. Staging and Treatment of Pancreatic Cancer

Stage	Classification	5 Yr Survival	Treatment
0	Tis, N0, M0		Surgical resection ± chemotherapy
IA	T1, N0, M0	14%	Same as above
IB	T2, N0, M0	12%	Same as above
IIA	T3, N0, M0	7%	Same as above
IIB	T1-3, N1, M0	5%	Same as above
III	T1-3, N2, M0 T4, any N, M0	3%	Borderline resectable, trial of chemotherapy and radiation
IV	any T, any N, M1	1%	Non-resectable, palliative treatments

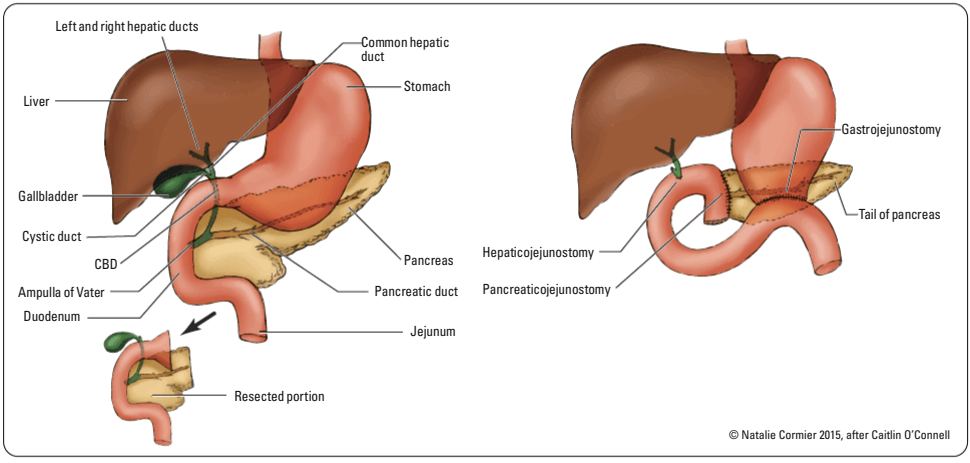

Figure 26. Schematic of Whipple resection showing the resected components

Spleen

Splenic Trauma

Clinical Features

- most common intra-abdominal organ injury in blunt trauma (especially can occur in people with splenomegaly)
- may have Kehr's sign
- patients may be hemodynamically unstable with altered mental status
- initial presentation may be masked by other injuries and contained ruptures may have few symptoms

Kehr's Sign
Left shoulder pain due to diaphragmatic irritation from splenic rupture, worsens with inspiration

Investigations

- FAST (used in trauma with hemodynamically unstable patients)
- CT with oral or IV contrast (once stable or when FAST negative)

Treatment

- non-operative
  - in stable patients: extended bed rest with serial hematocrit levels, close monitoring for 3-5 d; pediatric guidelines for days of bed rest is grade plus 1 (i.e. grade 3 splenic laceration requires 4 d of bed rest)
  - hemostatic control
  - splenic artery embolization if patient stable and one of: active contrast extravasation, splenic pseudoaneurysm, hemoperitoneum
- operative
  - hemodynamically unstable patients with positive FAST will undergo emergent operative surgical exploration
  - splenorrhaphy (suture of spleen) ± splenic wrapping with hemostatic mesh (if patient is hemodynamically stable)
  - splenectomy if patient unstable or high-grade injury or ongoing bleeding with hemodynamic instability
  - packing the spleen with temporary abdominal closure and relook laparotomy in 48 h

Splenectomy

Indications
- splenic trauma (most common reason for splenectomy), hereditary spherocytosis, primary hypersplenism, chronic immune thrombocytopenic purpura (ITP), splenic vein thrombosis causing esophageal varices, splenic abscess, thrombotic thrombocytopenic purpura (TTP), and sickle cell disease
- does not benefit all thrombocytopenic states (e.g. infection, most malignancies involving the bone marrow, drugs/toxins)
- probability of cure of ITP by splenectomy is 60-70%, may be predicted by response to IVIG

Indication of Splenectomy

SHIRTS
Splenic abscess/splenomegaly
Hereditary spherocytosis
Immune thrombocytopenic purpura
Rupture of spleen
Thrombotic thrombocytopenic purpura
Splenic vein thrombosis

Complications
- short-term
  - injury to surrounding structures (e.g. gastric wall, tail of pancreas) and their vascular supply
  - postoperative thrombocytosis, leukocytosis
  - thrombosis of portal, splenic, or mesenteric veins
  - subphrenic abscess
- long-term
  - post-splenectomy sepsis (encapsulated organisms): 4% of splenectomized patients (highest risk <16 yr)
  - splenosis: intra-abdominal "seeding" of splenic tissue during removal
  - increased risk of malignancy, DVT, and PE
- 50% mortality

Prophylaxis
- vaccinations, ideally 2 wk pre- or postoperative (pneumococcal, *H. influenzae*, and meningococcus)
- liberal use of penicillin especially in children <6 yr

Splenic Infarct

Pathophysiology
- splenic artery occlusion or oxygen-delivery insufficiency leading to parenchymal ischemia and necrosis
- can occur in sickle cell disease, thromboembolism, myelofibrosis, CML, and hypercoagulable states

Clinical Features
- patient can be asymptomatic or can have LUQ pain (70%), N/V, fever, chills, and Kehr's sign

Investigations
- CT with contrast; MRI
- peripheral blood smear abnormalities

Treatment
- non-operative: close follow-up, analgesia
- indications for splenectomy: complications such as rupture, abscess, persistent pseudocyst, bleeding, or sepsis

Breast

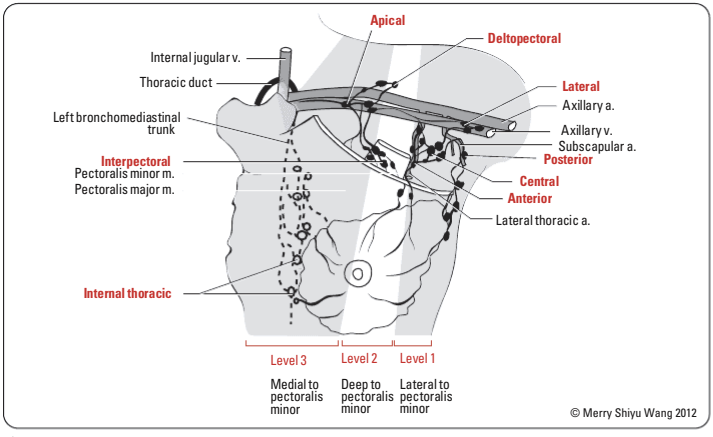

Figure 27. Anatomy of the breast

Levels of Axillary Lymph Nodes
Level I: lateral to pectoralis minor
Level II: deep to pectoralis minor
Level III: medial to pectoralis minor (higher level of nodal involvement = worse prognosis)

DDx for Breast Mass
Benign
- Fibrocystic changes
- Fibroepithelial lesions (fibroadenoma most common; benign phyllodes)
- Fat necrosis
- Papilloma/papillomatosis
- Galactocele
- Duct ectasia
- Ductal/lobular hyperplasia
- Sclerosing adenosis
- Lipoma
- Neurofibroma
- Granulomatous mastitis (e.g. TB, granulomatosis with polyangiitis, sarcoidosis)
- Abscess
- Silicone implant

Malignant
- Breast cancer (likely invasive, DCIS rarely forms a breast mass)
- Malignant phyllodes
- Angiosarcoma (rare)

Benign Breast Lesions

Three Categories
1. non-proliferative
2. proliferative without atypia
3. atypical hyperplasia

NON-PROLIFERATIVE LESIONS
- benign breast condition characterized by fibrous and cystic changes in the breast (fibrocystic changes/disease)
- most common: breast cysts
- other lesions include papillary apocrine change, epithelial-related calcifications, and mild hyperplasia of the usual type
- no increased risk of breast cancer
- age 30 to menopause (and after if hormone replacement therapy (HRT) used)
- clinical features
  - breast pain, focal areas of nodularity or cysts often in the upper outer quadrant, frequently bilateral, mobile, varies with menstrual cycle, and nipple discharge (straw-like, brown, or green)
- treatment
  - evaluation of breast mass (U/S, mammography as indicated) and reassurance
  - analgesia (e.g. ibuprofen, ASA)
  - for severe symptoms: OCP, danazol, bromocriptine

PROLIFERATIVE LESIONS – WITHOUT ATYPIA

Table 29. Proliferative Lesions - Without Atypia

		Clinical Features	Diagnosis	Treatment	Risk of Breast Cancer
Fibroadenoma	Most common breast tumour in women <30 yr	Nodules: firm, rubbery, discrete, well-circumscribed, non-tender, mobile, hormone-dependent (unlike cysts), needle aspiration yields no fluid	Core or excisional biopsy sometimes required if concerned about malignancy U/S and FNA alone cannot differentiate fibroadenoma from phyllodes tumour	Generally conservative serial observation Consider excision if size 2-3 cm and growing on serial U/S (q6 mo x 2 yr is usual follow-up), if symptomatic, formed after age 35, patient preference or features on core biopsy suggestive of a phyllodes tumour	Increased if complex, adjacent atypia or strong family history of breast cancer
Intraductal Papilloma	Solitary intraductal benign polyp	Can present as nipple discharge (most common cause of spontaneous, unilateral, bloody nipple discharge = pathologic nipple discharge), breast mass, nodule on U/S		Surgical excision of involved duct to ensure no atypia	Can harbour areas of atypia or DCIS
Usual Ductal Hyperplasia	Increased number of cells within the ductal space	Incidental finding on biopsy of mammographic abnormalities or breast masses		None required	Generally low-risk, slightly increased if moderate or florid hyperplasia
Sclerosing Adenosis	Lobular lesion with increased fibrous tissue and glandular cells	Mass or mammographic abnormality		None required	Low-risk

ATYPICAL HYPERPLASIA
- can involve ducts (atypical ductal hyperplasia) or lobules (atypical lobular hyperplasia)
- cells lose apical-basal orientation
- increased risk of breast cancer
- diagnosis: core or excisional biopsy
- treatment: complete resection, risk modification (avoid exogenous hormones), close follow-up

OTHER LESIONS

Fat Necrosis
- uncommon, result of trauma (may be minor, positive history in only 50%), after breast surgery (i.e. reduction)
- firm, ill-defined mass with skin or nipple retraction, ± tenderness, ± ecchymosis
- regress spontaneously, but complete imaging ± biopsy to rule out carcinoma
- oil cysts on mammography are pathognomonic for fat necrosis

Mammary Duct Ectasia
- obstruction of a subareolar duct (see Obstetrics, *Mastitis, OB48*)

Abscess
- lactational vs. non-lactational (periductal/subareolar) (see Obstetrics, *Mastitis, OB48*)

Breast Cancer

Epidemiology
- leading cancer diagnosis in women in North America, 2nd leading cause of cancer mortality in women
- 1 in 8 (12.9% lifetime risk) women in Canada will be diagnosed with breast cancer in their lifetime
- 1 in 31 women in Canada will die from breast cancer
- all age relative survival is 87%

Female sex, followed by age, are the two greatest risk factors for breast cancer

Risk Factors
- sex (99% female)
- age (83% >50 yr)
- personal history of breast cancer and/or prior breast biopsy (regardless of pathology)
- family history of breast cancer (greater risk if relative was first degree and premenopausal)
- estrogen exposure
  - nulliparity, first pregnancy >30 yr, menarche <12 yr, or menopause >55 yr
  - decreased risk with lactation, early menopause, and early childbirth
  - >5 yr HRT use, >10 yr OCP use
- high breast density
- radiation exposure (e.g. mantle radiation for Hodgkin's disease)
- BRCA1 and BRCA2 gene mutations
- alcohol use, obesity, and sedentary lifestyle

Any palpable dominant breast mass requires further investigation

Male Breast Cancer (<1%)
- most commonly invasive ductal carcinoma
- often diagnosed at later stages
- stage-for-stage similar prognosis to breast cancer in females
- consider genetic testing: most often hormone receptor positive

Breast Lymphatic Drainage:
Axillary lymph nodes
Internal mammary lymph nodes
Infra-/supra-clavicular lymph nodes

Investigations
- see margin for physical exam findings
- mammography
  - indications: screening guidelines (see Family Medicine, FM4)
  - findings indicative of higher risk of malignancy
    - mass that is poorly defined, spiculated border
    - microcalcifications
    - architectural distortion
    - interval mammographic changes
  - normal mammogram does not rule out suspicion of cancer based on clinical findings
- other radiographic studies
  - U/S: differentiate between cystic and solid
  - MRI: high sensitivity, low specificity. Use annual MRI and mammography for patients with 25% lifetime risk of breast cancer
  - Digital Breast Tomosynthesis (DBT): improved lesion localization and characterization in noncalcified lesions
  - galactogram/ductogram (for nipple discharge): identifies lesions in ducts
  - metastatic workup indicated in Stage II-IV disease: bone scan, abdominal U/S, CXR (or CT chest/abdomen/pelvis), CT head (if specific neurological symptoms)

Physical Exam Findings in Breast Cancer:
Lump/mass: Often firm, irregular, non-mobile, unilateral
Pain: Usually thought of as painless, however pain may be present with rapidly expanding tumours or inflammatory cancer
Inflammation (and peau d'orange): There are many benign causes of inflammation, however inflammatory cancer can present similarly
Nipple or skin retractions/changes: Nipple or skin retractions/changes: Attachment of the tumour to skin/nipple may cause retraction/distortion
Nipple discharge: Majority due to benign causes, bloody spontaneous discharge should be investigated for malignancy

Diagnostic Procedures
- "triple test" for diagnosis of breast cancer:
  - clinical breast exam
  - imaging
    - ≥30 yr: mammography and U/S
    - <30 yr or lactating or pregnant: U/S (high breast density)
  - pathology (biopsy)
    - U/S or mammography guided core needle biopsy: most common
    - needle aspiration: for palpable cystic lesions; send fluid for cytology if blood or cyst does not completely resolve
    - excisional biopsy: only performed as second choice to core needle biopsy; should not be done for diagnosis if possible

Genetic Screening
- consider testing for BRCA1/2 if:
  - young patient (<35 yr)
  - bilateral breast cancer in patients <50 yr
  - patient diagnosed with breast AND ovarian cancer
  - strong family history of breast/ovarian cancer
  - family history of male breast cancer

Phyllodes tumours are rare fibroepithelial breast tumours that can be benign or malignant that mostly affect women from 35-55 yr

Staging
- patients are assigned a clinical stage preoperatively (cTNM); following surgery the pathologic stage is determined (pTNM)
- clinical
  - tumour size by palpation, mammogram, U/S, and/or MRI
  - nodal involvement by palpation, imaging
  - metastasis by physical exam, CXR, abdominal U/S (or CT chest/abdomen/pelvis), and bone scan (usually done postoperative if node-positive disease)
- pathological
  - tumour size and type
  - grade: modified Bloom and Richardson score (I to III) – histologic, nuclear, and mitotic grade
  - number of axillary nodes positive for malignancy out of total nodes resected, extranodal extension, and sentinel lymph node biopsy (SLNB) positive/negative
  - tumour biology: estrogen receptor (ER), progesterone receptor (PR), and HER2/neu oncogene status
  - margins: for invasive breast cancer, negative margin is sufficient; for DCIS prefer 2 mm margin
  - lymphovascular invasion (LVI)
  - extensive *in situ* component (EIC): DCIS in surrounding tissue
  - involvement of dermal lymphatics (inflammatory) – automatically Stage IIIb

Table 30. TNM Classification System for Staging of Breast Cancer (AJCC 2017)

Primary Tumour (T)		Regional Lymph Nodes (N)		Distant Metastasis (M)	
TX	Primary tumour cannot be assessed	**NX**	Regional lymph nodes cannot be assessed	**M0**	No distant metastasis
T0	No evidence of primary tumour	**N0**	No regional lymph node metastasis	**M1**	Distant metastasis
Tis	Ductal carcinoma *in situ*	**N1**	Involvement of 1-3 axillary lymph nodes and/or clinically negative internal mammary nodes on sentinel node biopsy		
T1	Tumour ≤2 cm in greatest dimension				
N2	Involvement of 4-9 axillary lymph nodes or clinically positive ipsilateral internal mammary lymph node				
T2	Tumour >2 cm but ≤5 cm in greatest dimension				
T3	Tumour >5 cm in greatest dimension				
T4	Tumour of any size with direct extension to chest wall and/or skin				

Favourable Features	Unfavourable Features
<2 cm	>5 cm
Grade I (low grade)	Grade III (high grade)
Node negative	Node positive
ER positive	ER negative
Mucinous pattern	Inflammatory cancer
	Her2/Neu positive
	Positive margins
	Lymphovascularinvasion
	Epidermal inclusion cyst
	Dermal lymphatics involved

Pathology

NON-INVASIVE

Ductal Carcinoma *in situ* (DCIS)
- proliferation of malignant ductal epithelial cells completely contained within breast ducts, often multifocal
- 80% non-palpable; detected by screening mammogram as microcalcifications
- risk of invasive ductal carcinoma in same breast up to 35% in 10 yr
- treatment
  - lumpectomy with wide excision margins + radiation (5-10% risk of invasive cancer)
  - mastectomy if large area of disease, high grade, or multifocal (risk of invasive cancer reduced to 1%)
  - possibly tamoxifen as an adjuvant treatment
  - 99% 5 yr survival

Analysis of Circulating Tumour DNA to Monitor Metastatic Breast Cancer
NEJM 2013;368:1199-1209
Study: The quantification of circulating tumour DNA, cancer antigen 15-3 (CA 15-3), and circulating tumour cells in 30 women with metastatic breast cancer receiving systemic therapy. The results were compared with radiographic imaging of tumours.
Results/Conclusions: Circulating tumour DNA was detected in 97% of women and showed greater correlation with changes in tumour burden than did CA 15-3 or circulating tumour cells, providing the earliest measure of treatment response in 53% of women. CA 15-3 and circulating tumour cells were detected in 78% and 87% of women, respectively. Circulating tumour DNA may therefore be an informative biomarker for metastatic breast cancer.

Lobular Carcinoma *in situ* (LCIS)
- neoplastic cells completely contained within breast lobule
- no palpable mass and no mammographic findings; usually incidental finding on breast biopsy for another indication
- LCIS is a risk factor for invasive carcinoma (approximately 1%/yr)
- treatment
  - if diagnosed on core biopsy, excisional biopsy necessary to rule out malignancy
  - if diagnosed on excisional biopsy, wide excision not needed since LCIS is often multicentric and not managed as precursor lesion
  - clinical follow-up and surveillance; consider chemoprevention (e.g. tamoxifen)

10 Year Survival after Breast-Conserving Surgery Plus Radiotherapy Compared with Mastectomy in Early Breast Cancer in The Netherlands: A Population-Based Study
Lancet Oncol 2016;17(8):1158
See Landmark General and Thoracic Surgery Trials table for more information on the 10 yr survival after breast-conserving surgery plus radiotherapy compared with mastectomy in early breast cancer.

INVASIVE

Invasive Ductal Carcinoma (most common 80%)
- originates from ductal epithelium and infiltrates supporting stroma
- four types: tubular, mucinous, medullary, and inflammatory
- characteristics: hard, scirrhous, infiltrating tentacles, and gritty on cross-section
  - divided into three grades based on cytologic and architectural features: well differentiated (grade 1), moderately differentiated (grade 2), poorly differentiated (grade 3)

Invasive Lobular Carcinoma (8-10%)
- originates from lobular epithelium, 20% bilateral
- subtle thickening originating from lobes/lobules; usually positive for estrogen and progesterone receptors
- harder to detect on mammography due to lack of microcalcifications (may benefit from MRI)

Paget's Disease of the Breast (1-3%)
- ductal carcinoma that invades nipple with scaling, ulceration, erythema, and eczematous lesion

Inflammatory Carcinoma (1-3%)
- most aggressive form of breast cancer
- ductal carcinoma that grows in nests (vs. solid tumour); invades and blocks dermal lymphatics
- clinical features: erythema, skin edema, warm, swollen, and tender breast ± lump, nipple changes
- peau d'orange indicates advanced disease (IIIb-IV)

Sarcomas: rare
- most commonly phyllodes tumour, a variant of fibroadenoma with potential for malignancy
- can also be angiosarcomas – after previous radiation

Lymphoma: rare

Other
- papillary, medullary, mucinous, and tubular cancers
- generally better prognosis

Treatment

Table 31. Breast Cancer Treatment by Stage

Stage	Primary Treatment Options	Adjuvant Systemic Therapy
0 (*in situ*) Tis, N0, M0	BCS + radiotherapy BCS alone if margins >1 cm and low nuclear grade Mastectomy* ± SLNB	Consider postoperative tamoxifen for ER+, trastuzumab for HER2+
I IA: T1, N0, M0 IB: T1, N1mi, M0	BCS + axillary node dissection + radiotherapy Mastectomy* + axillary node dissection/SLNB	May not be needed; discuss risks/benefits of chemotherapy and tamoxifen
II A: T0, N1, M0 T1, N1, M0 T2, N0, M0 B: T2, N1, M0 T3, N0, M0	BCS + axillary node dissection + radiotherapy Mastectomy* + axillary node dissection/SLNB	Chemotherapy for premenopausal women or postmenopausal and ER negative, followed by tamoxifen if ER+
III A: T0, N2, M0 T1, N2, M0 T2, N2, M0 T3, N1, M0 T3, N2, M0 B: T4, N0, M0 T4, N1, M0 T4, N2, M0	Likely mastectomy + axillary node dissection + radiotherapy after chemotherapy (neoadjuvant)	Neoadjuvant therapy should be considered (i.e. preoperative) especially if not resectable chemotherapy and/or hormone therapy. Adjuvant radiation and chemotherapy may also be appropriate (i.e. postoperative)
Inflammatory	Mastectomy + axillary node dissection + radiotherapy	Neoadjuvant therapy
IV any T, any N, M1	Surgery as appropriate for local control	Primary treatment is systemic therapy (i.e. chemotherapy) and/or hormone therapy

BCS = breast conserving surgery; SLNB = sentinel lymph node biopsy
*If no reason to select mastectomy, the choice between BCS + radiotherapy and mastectomy can be made according to patient's preference since choice of local treatment does not significantly affect survival if local control is achieved

PRIMARY SURGICAL TREATMENT

Breast Conservation Surgery (BCS)

- lumpectomy must be combined with radiation for survival equivalent to mastectomy
- contraindications include
  - high-risk of local recurrence (e.g. extensive malignant-type calcifications on mammogram), and multifocal primary tumours
  - failure to obtain tumour-free margins after re-excision
  - not suitable for radiation therapy (pregnancy, previous radiation, and collagen vascular disease)
  - large tumour size relative to breast

Mastectomy

- radical mastectomy (rare): removes all breast tissue, skin, pectoralis muscle, and axillary nodes
- modified radical mastectomy (MRM): removes all breast tissue, skin, and axillary nodes
- simple mastectomy: removes all breast tissue and skin
- see Plastic Surgery, PL38 for breast reconstruction

Sentinel Lymph Node Biopsy (SLNB)

- performed in women with clinically node-negative invasive breast cancer and those with extensive DCIS who are undergoing mastectomy
- patients with clinically suspicious nodes should get U/S + FNA prior to decision to proceed with SLNB
- technetium-99 ± blue dye injected at tumour site prior to surgery to identify sentinel node(s)
- intraoperative frozen section evaluated can be considered
- proceed with ALND if >3 positive nodes, with 1-3 nodes whole breast radiation therapy may be an alternative
- 5% false negative rate

Axillary Lymph Node Dissection (ALND)

- perform in patients with:
  - locally advanced (T4a, b, c) or inflammatory breast cancer
  - clinically node-positive axilla, confirmed by FNA or core biopsy, in a patient for whom neoadjuvant chemotherapy is not planned
  - several other specific cases (sentinel or axillary nodes, which remain positive after neoadjuvant chemotherapy, axillary recurrence following previous breast cancer treatment, among others)
- side effects: risk of arm lymphedema (10-15%), especially if getting radiation therapy, decreased arm sensation, and shoulder pain

BCS can be offered to most women with stage I/II disease

There is no survival benefit of mastectomy over lumpectomy plus radiation for stage I and II disease

Effect of Radiotherapy after Mastectomy and Axillary Surgery on 10 Year Recurrence and 20 Year Breast Cancer Mortality: Meta-Analysis of Individual Patient Data for 8135 Women in 22 Randomised Trials
EBCTCG (Early Breast Cancer Trialists' Collaborative Group)
Lancet 2014;383(9935):2127-2135
Study: Assessed the effect of radiotherapy in women with one to three positive lymph node(s) after mastectomy and axillary dissection in a meta-analysis of 8135 women in 22 trials.
Results: For 700 women with axillary dissection and no positive nodes, radiotherapy had no significant effect on local regional recurrence, overall recurrence, or breast cancer mortality. For 1314 women with axillary dissection and one to three positive nodes, radiotherapy reduced local regional, overall recurrence, and breast cancer mortality. 1133 of these 1314 women were in trials in which systemic therapy (cyclophosphamide, methotrexate, and fluorouracil, or tamoxifen) was given in both trial groups and radiotherapy again reduced local regional recurrence, overall recurrence, and breast cancer mortality. For 1772 women with axillary dissection and four or more positive nodes, radiotherapy reduced local regional recurrence, overall recurrence, and breast cancer mortality.
Conclusion: Post mastectomy and axillary dissection, radiotherapy reduced both recurrence and breast cancer mortality in the women with one to three positive lymph nodes in these trials even when systemic therapy was given.

ADJUVANT/NEOADJUVANT

Radiation
- indications
  - decrease risk of local recurrence; almost always used after BCS, sometimes after mastectomy
  - inoperable locally advanced cancer
  - axillary nodal radiation may be added if nodal involvement

Hormonal
- indications
  - ER positive plus node-positive or high-risk node-negative
  - selective estrogen receptor modulators (SERM) if premenopausal (e.g. tamoxifen) or aromatase inhibitors if postmenopausal (e.g. anastrozole); optimal duration 5-10 yr
  - other options include ovarian ablation (e.g. goserelin/GnRH agonist, oophorectomy), progestins (e.g. megestrol acetate), and androgens (e.g. fluoxymesterone)
  - palliation for metastatic disease

Chemotherapy
- indications
  - ER negative plus node-positive or high-risk node-negative
  - triple-negative disease (ER/PR and HER2-negative) - more common in younger and African-American women
  - ER positive and young age
  - stage I disease at high-risk of recurrence (high grade, lymphovascular invasion)
  - palliation for metastatic disease
  - for HER2 positive breast cancer, add trastuzumab ± pertuzumab to the chemotherapy regimen

Effect of Axillary Dissection vs. No Axillary Dissection on 10-Year Overall Survival Among Women With Invasive Breast Cancer and Sentinel Node Metastasis: The ACOSOG Z0011 (Alliance) Randomized Clinical Trial
JAMA 2017;318(10):918-926
Purpose: Assessed whether the 10 yr overall survival of patients with sentinel lymph node metastases treated with breast-conserving therapy and sentinel lymph node dissection (SLND) alone without axillary lymph node dissection (ALND) is noninferior to that of women treated with axillary dissection.
Results: The 10 yr overall survival was 86.3% in the SLND alone group and 83.6% in the ALND group. The 10 yr disease-free survival was 80.2% in the SLND alone group and 78.2% in the ALND group. 10 yr regional recurrence did not differ significantly between the 2 groups.
Conclusion: Among women with T1 or T2 invasive primary breast cancer, no palpable axillary adenopathy, and 1 or 2 sentinel lymph nodes containing metastases, 10-yr overall survival for patients treated with SLND alone was noninferior to overall survival for those treated with ALND.

FOLLOW-UP

Post-Treatment Follow-Up
- assessment and physical exam q3-6 mo x 3 yr, q6-12 mo x 2 yr, and annually thereafter
- following BCS mammography q6-12 mo; can reduce to annual once stable, no other routine imaging unless clinically indicated
- women who receive tamoxifen should have regular gynecologic follow-up (increased risk of endometrial cancer)

Local/Regional Recurrence
- recurrence in treated breast or ipsilateral axilla
- 1% per yr up to maximum of 15% risk of developing contralateral malignancy
- 5x increased risk of developing metastases

Metastasis
- bone > lungs > pleura > liver > brain
- treatment is palliative: hormone therapy, chemotherapy, radiation
- overall survival of metastatic breast cancer is 36-60 mo

Surgical Endocrinology

Thyroid and Parathyroid

- see Endocrinology, E24

Thyroidectomy

- indications: some thyroid cancers or suspicious thyroid nodules, metastases to thyroid, large (substernal) or symptomatic thyroid goitre, toxic nodules, or some patients with definitive management of Graves' disease (not candidates for RAI). There are minimally invasive approaches to thyroid nodules including Scarless (Transoral)Thyroidectomy and RFA (Radiofrequency Ablation) of large symptomatic or hot thyroid nodules.
- preoperative workup: thyroid U/S for thyroid nodules, FNA for nodules ≥1 cm with suspicious U/S features or for most nodules ≥1.5 cm with lower suspicion U/S features, and CT neck for preoperative staging when advanced disease is suspected
- complications
  - lobectomy: recurrent laryngeal nerve palsy (hoarseness or swallowing issues), neck hematoma
  - total thyroidectomy: same as above plus hypoparathyroidism/hypocalcemia, bilateral RLN palsy (potentially requiring tracheostomy)
  - 20-75% of patients need thyroxine after lobectomy and 100% need thyroxine after total thyroidectomy

Parathyroidectomy

- elevated calcium found for any reason as an outpatient (but also incidental finding as inpatient) is likely primary hyperparathyroidism and should be investigated further
- indications: symptomatic primary hyperparathyroidism (osteoporosis/stones), asymptomatic primary hyperparathyroidism with specific laboratory criteria (profoundly elevated serum Ca^{2+}, hypercalciuria/asymptomatic kidney stones, Cr clearance <30% normal, <50 yr)
- contraindications: familial hypocalciuric hypercalcemia
- preoperative localization to find parathyroid adenoma. Localizing studies include: 99mTc sestamibi scanning with ± SPECT (single-photon emission computed tomography), U/S, contrast CT
- complications: recurrent/superior laryngeal nerve injury, postoperative hypocalcemia, infection, and bleeding

Adrenal Gland

- see Endocrinology, E33 and E40
- functional anatomy
  - cortex: glomerulosa (mineralocorticoids), fasciculata (glucocorticoids), and reticularis (sex steroids)
  - medulla: catecholamines (epinephrine, norepinephrine)
- types of adrenal tumours: functional (e.g. Cushing's syndrome, Conn's syndrome, pheochromocytoma) or non-functional

INCIDENTALOMA

- adrenal mass discovered by investigation of unrelated symptoms/issues

Epidemiology

- benign adenoma (70-80%) > metastases to adrenal (22%) >> cyst carcinoma, pheochromocytoma, neuroblastoma
- metastasis to adrenal gland from: lung > breast, colon, lymphoma, melanoma, and kidney
- peak incidence of carcinoma: females ages 50-60, risk decreases with increasing age and male gender

Investigations

- CT: size >4-6 cm is best predictor of primary adrenal carcinoma (92% are >6 cm), MRI is not as good as CT and does NOT need to be done after CT
- functional studies
  - pheochromocytoma: plasma metanephrines (highly specific and sensitive). If not available, 24 h urine catecholamines
  - Cushing's: 24 h urine cortisol or 1 mg overnight dexamethasone suppression test
  - aldosteronoma: electrolytes, AM aldosterone, AM plasma renin activity level, ARR (Aldosterone-Renin-Ratio). If inconclusive, saline suppression test if appropriate
  - not routinely - only if clinical suspicion: adrenal androgens (17-OH progesterone and DHEAS)
- FNA biopsy: NOT APPROPRIATE in most cases. Diagnostic adrenalectomy by high volume endocrine surgeon ideal if diagnostic uncertainty

Treatment
- functional tumour: resect
- non-functional tumour
  - >4 cm: consider resection
  - <4 cm: follow-up imaging in 6-12 mo, resect if >1 cm enlargement
  - genetic testing important for ALL Pheochromocytoma/paragangliomas as >30% are related to genetic syndrome

Pancreas

INSULINOMA
- tumour that secretes insulin
- most common pancreatic endocrine neoplasm; 10% associated with MEN1 syndrome

Clinical Features
- Whipple's triad
- palpitations, trembling, diaphoresis, confusion, seizure, and personality changes

Investigations
- blood work: decreased serum glucose and increased serum insulin and C-peptide, pro-insulin
- CT, EUS, MRI: insulinomas evenly distributed throughout head, body, tail of pancreas

Treatment
- only 10% are malignant
- enucleation of solitary insulinomas may be done endoscopically
- tumours >2 cm located close to the pancreatic duct may require pancreatectomy or pancreaticoduodenectomy

GASTRINOMA
- tumour secreting gastrin; cause of Zollinger-Ellison syndrome, associated with MEN1

Clinical Features
- abdominal pain, PUD, severe esophagitis
- multiple ulcers in atypical locations refractory to antacid therapy

Investigations
- blood work: serum gastrin levels (usually >1000 pg/mL), secretin stimulation test
- endoscopy: 90% of patients develop peptic ulcers
- CT, EUS, MRI: 70-90% found in Passaro's triangle (head of pancreas medially, 2nd portion of duodenum inferiorly, and the confluence of the cystic and CBD superiorly)
- somatostatin receptor scintigraphy scan

Treatment
- 50% are malignant
- surgical resection of tumour dependent on location
- non-surgical treatment: high dose PPI, octreotide (somatostatin analogs)
- radiation therapy may be considered for nonsurgical candidates

VASOACTIVE INTESTINAL PEPTIDE-SECRETING TUMOUR
- tumour secreting VIP; commonly located in the distal pancreas and most are malignant when diagnosed

Clinical Features
- severe watery diarrhea causing dehydration, anorexia, weakness, and electrolyte imbalance (hypokalemia)

Investigations
- blood work: serum VIP levels
- CT, MRI, EUS

Treatment
- repletion of fluid and electrolytes
- somatostatin analogues
- surgical resection/palliative debulking

Whipple's Triad
- Symptomatic fasting hypoglycemia
- Serum glucose <2.8 mmol/L
- Relief of symptoms when glucose is administered

Zollinger-Ellison Syndrome
Characterized by gastric acid hypersecretion caused by secretion of gastrin from gastrinomas; patient experiences diarrhea and abdominal pain, as well as peptic disease and reflux disease

Hypertrophic Pyloric Stenosis
Non-bilious emesis in infants is the classic presentation

Rule of 2s for Meckel's Diverticulum
- **2**% of the population
- **2**:1 male-to-female ratio
- Symptomatic in **2**% of cases
- Found within **2** feet (10-90 cm) of the ileocecal (IC) valve
- **2** inches in length
- **2** inches in diameter
- **2** types of tissue (ileal or ectopic gastric, pancreatic)
- Often present by **2** y/o

Pediatric Surgery

Condition	Epidemiology and Risk Factors	Pathophysiology	Clinical Features and History	Physical Exam	Investigations	Treatment	Prognosis
Hydrocele (see Urology, U32)	1-2% of live births Majority resolve spontaneous by 1 yr M:F=6:1 Prematurity	Communicating hydroceles: processus vaginalis connects peritoneum with tunica vaginalis, so peritoneal fluid flows freely between the two with potential for abdominal contents to enter groin (i.e. inguinal hernia) Noncommunicating hydroceles: processus vaginalis is closed and more fluid produced than absorbed in tunica vaginalis; in older children, may be secondary to testicular pathology (e.g. reactive hydrocele)	Painless scrotal mass Communicating hydroceles increase in size with standing or valsalva, may be absent in the morning and large in the evening	Transillumination suggests hydrocele Silk glove sign: gently palpating hydrocele sac over pubic tubercle feels like rubbing silk on silk	U/S if suspect pathology	Most resolve spontaneously by 1 yr Surgical repair if: Persistence >2 yr Pain Fluctuating in size which suggests communication Cosmetic reasons Infection	<2% recurrence
Hypertrophic Pyloric Stenosis	0.03-1.0% of live births Can present at 1-20 wk, most commonly at 6-8 wk M:F=4:1 Early erythromycin exposure (<13 d)	Acquired pyloric circular muscle hypertrophy results in gastric outlet obstruction Hypovolemia caused by emesis of gastric contents causes hypochloremic, hypokalemic metabolic alkalosis Electrolyte exchange based volume retention in kidneys results in paradoxical aciduria	Projectile non-bilious vomiting Vomiting 30-60 min after feeds Hungry after vomiting Dehydration (variable severity)	Smooth oblong 1-2 cm "olive" mass palpable above umbilicus in the RUQ Visible left-to-right gastric contraction "waves" after feeding	Electrolytes (assess hypochloremia, dehydration) U/S shows pyloric length 17 mm, muscle thickness >4 mm Upper GI series (necessary only when U/S is unavailable or non-diagnostic) will show "string sign"	Fluid resuscitate with NS, correct electrolyte and acid/base abnormalities with D5, 1/2NS + 20 mEq/L KCl at maintenance rate NG tube decompression unnecessary Pyloromyotomy, open (Ramstedt vs. transumbilical or laparoscopic approach) is the definitive treatment Alternative therapies such as TPN/wait or atropine impractical due to long time course of effect	Pyloromyotomy curative
Congenital Diaphragmatic Hernias 3 types: Posterolateral (Bochdalek) Left-sided (85%) Right-sided (13%) Bilateral, rare, often fatal Anterior (Morgagni) Hiatus	1 in 2000 to 5000 live births Presents within hours of life although some cases of delayed presentation M=F >10% are associated with other congenital anomalies Prenatal diagnosis common	Combinations of small bowel, large bowel, stomach, and solid viscera (spleen, liver) may herniate into thorax Varying degrees of pulmonary hypoplasia and pulmonary hypertension possible	Early respiratory distress Cyanosis Scaphoid abdomen Prenatal diagnosis	Decreased air entry ± bowel sounds in the chest Displaced heart sounds	Prenatal US/MRI ABG CXR (bowel loops in hemithorax, shifted heart) Echocardiography Genetic consultation if warranted	Intubate/ventilate Orogastric suction Period of respiratory stabilization due to associated pulmonary hypoplasia (may require extracorporeal membrane oxygenation) Surgical repair after stable by hernia reduction and closure of diaphragmatic defect open vs. thoracoscopic vs. laparoscopic with or without prosthetic or muscular patch depending on size of defect	Better outcomes in later presentations Neurodevelopmental impairment Hearing deficit (40%) Associated GERD MSK defects chest wall and scoliotic defects as potential complications of thoracotomy Long-term surveillance for potential recurrence Failure to thrive Chronic lung disease if severe hypoplasia
Meckel's Diverticulum Most common remnant of vitelline duct that connects yolk sac with primitive midgut	1-3% of population M:F=3:1 Present most frequently during first 5 yr of life Symptomatic in 2% of cases	Failure of vitelline duct to regress 5-7 wk *in utero*; 50% contain heterotopic tissue (e.g. gastric mucosa, ectopic pancreas); other associated anomalies include omphalomesenteric fistula, umbilical sinus, umbilical cyst, and fibrous band	BRBPR (heterotopic gastric mucosa in Meckel's causing mucosal ulceration and bleeding in adjacent small bowel mucosa) Abdominal sepsis (Meckel's diverticulitis ± perforation) Small bowel volvulus around fibrous band Intestinal obstruction symptoms	Tenderness and distension (lower abdomen) near umbilicus	AXR Meckel scan: scan for ectopic gastric mucosa with technetium Tc99m pertechnetate IV (sensitivity 85%, specificity 95%)	Stabilize, resection by laparotomy or laparoscopy ± incidental appendectomy	Resection curative
Malrotation	1 in 500 live births 1/3 present by 1 wk of age, 3/4 by 1 mo of age, 90% by 1 yr of age M:F=1:1 Higher incidence among patients with cardiac anomalies or heterotaxy syndromes	Failure of gut to normally rotate around SMA with associated abnormal intestinal attachments and anatomic positions Represent a spectrum of rotational abnormalities including complete non-rotation (which is not at high-risk for volvulus)	Cardinal sign: bilious emesis (especially if abdomen nondistended) If bilious emesis with distended abdomen, consider surgical exploration to rule out volvulus Rectal bleed (late/ominous signs) Intermittent symptoms	Bilious drainage from NG tube Tachycardic, pale Diaphoretic Flat abdomen Tenderness	AXR: proximal SBO, double-bubble sign, intestinal wall thickened Immediate UGI: dilated duodenum, duodenojejunal segment (Ligament of Treitz) right of midline and not fixed posteriorly over spinal column, "corkscrew" sign indicating volvulus U/S: "whirlpool" sign, abnormal SMA/SMV relationship indicates UGI to rule out rotational anomalies	IV antibiotics Fluid resuscitation EMERGENT LAPAROTOMY Ladd procedure: counterclockwise reduction of midgut volvulus, division of Ladd's bands, division of peritoneal attachments between cecum and abdominal wall that obstruct duodenum, broadening of the mesentery (open folded mesentery like a book and divide congenital adhesions), ± appendectomy Positioning the bowel into non-rotation (SBO in right abdomen, LBO in left abdomen)	Mortality related to length of bowel loss: 10% necrosis 100% survival rate, 75% necrosis 35% survival rate Recurrence 2-6%

Condition	Epidemiology and Risk Factors	Pathophysiology	Clinical Features and History	Physical Exam	Investigations	Treatment	Prognosis
Gastroschisis	1 in 2000 live births Antenatal diagnosis common Increased risk with younger maternal age and associated with IUGR Rate slightly higher in male infants Smoking	Defect of abdominal wall near umbilicus, with free extrusion of intestine into amniotic cavity No specific environmental factor identified Defect in embryogenesis unclear	Not associated with genetic syndromes 10% with intestinal atresia Some cases associated with short bowel syndrome due to antenatal volvulus and necrosis of herniated bowel	Hollow viscera (stomach, small and large bowels) Defect lateral to cord (usually right) Bowel may be inflamed, thickened, matted, foreshortened Defect size variable	Prenatal U/S Elevated MS-AFP	NG tube decompression IV fluids IV antibiotics Keep viscera moist and protected until surgical reduction with primary abdominal closure or staged closure with silo May have bowel dysmotility requiring motility medications	>90% survival rate
Omphalocele	1 in 5000 live births Antenatal diagnosis common Lower gestational age Increased maternal age M:F=1.5:1	Defect of abdominal wall and umbilical ring, with extrusion of sac-covered viscera (amnion, Wharton's jelly, peritoneum) through the umbilical ring Duhamel's theory failure of body wall morphogenesis Commonly associated with rotational abnormalities of the intestine	30-70% associated with genetic syndromes (e.g. Pentalogy of Cantrell, congenital heart disease, Beckwith-Wiedemann syndrome, Trisomy 18) Associated pulmonary hypoplasia	Hollow viscera (stomach, small and large bowels, often liver) Sac present with cord attached	Prenatal U/S Elevated MS-AFP	NG tube decompression IV fluids, IV antibiotics Small defect (<2 cm): Primary closure Medium (2-4 cm) and large (>4 cm) defects: silver sulfadiazine coupled with compression dressing (to allow epithelialization and gradual reduction) or Silon Silo Pouch, followed by future repair ± mesh	40-70% survival rate Higher survival rates most likely related to antenatal mortality of fetuses with giant omphaloceles
Umbilical Hernias	Incidence 2-14% Increases with prematurity Decreases with increasing age	Incomplete closure of peritoneal and fascial layers within umbilicus by 4 yr Hernia is peritoneum-lined and skin-covered Size of fascial defect determines chances of spontaneous closure	Majority asymptomatic Majority (95%) spontaneously resolve by age 4 Incarceration prior to age 5 very rare Most symptoms occur in late adolescence or adulthood	Protrusion from umbilicus Different from less common abdominal wall hernias that do not spontaneously resolve (e.g. epigastric hernias) Most defects >1.5 cm in infancy will not close spontaneously	None if uncomplicated	Repair if not spontaneously closed by age 5 Earlier repair of large "proboscoid" hernias with extensive skin stretching may be warranted for cosmetic reasons Simple primary closure of fascial defect	Rarely become incarcerated Low risk of recurrence
Intestinal Atresia	Incidence 2-14% May be antenatally diagnosed by dilated bowel loops or "double-bubble" sign on x-ray for duodenal atresia Decreased with increasing age	Duodenal failure of bowel to recanalize after endodermal epithelium proliferation (wk 8-10) Jejunal/ileal acquired as a result of vascular disruption → ischemic necrosis → resorption of necrotic tissue → blind distal and proximal ends Colonic mechanism unknown, thought to be similar to small bowel atresia	Gastric distension and vomiting (usually bilious) Duodenal may be associated with other anomalies (tracheoesophageal fistula, cardiac, renal, and vertebral anomalies), 24-28% have Down syndrome Jejunal/ileal within 2 d of birth, may be associated with CF Colonic within 3 d of birth	Complete physical Special attention to abdominal exam, perineum, and anus Include evaluation of respiratory distress and signs of volume depletion Congenital anomalies Jaundice	Contrast enema ± UGI with small bowel follow through (SBFT) Group and screen INR and PTT if for surgery	NPO NG tube decompression Fluid resuscitation TPN Broad spectrum antibiotics Duodenal duodenoduodenostomy or duodenojejunostomy Jejunal/ileal primary anastomosis; or if atresia associated with short bowel then may create end stoma or defer surgery for bowel lengthening procedures Colonic primary anastomosis	Long-term survival: Duodenal 86% Jejunal/ileal 84% Colonic 100%
Congenital Aganglionic Meirschsprung's Disease	1 in 5000 births M:F=3:1 to 4:1, approaches 1:1 when whole colon involved Can have aganglionosis of small bowel as well Familial Hirschsprung's in <5% of cases	Defect in migration of neurocrest cells to intestine resulting in aganglionic bowel that fails to peristalse and internal sphincter that fails to relax (internal anal sphincter achalasia) causing functional and partial mechanical obstruction, respectively Starts in the rectum and variable involvement proximally; RET mutation	Failure to pass meconium spontaneously within 48 h of life (95% pass meconium within 24 h, 5% within 48 h) Symptoms of bowel obstruction: abdominal distension, constipation, bilious emesis Enterocolitis/sepsis Failure to thrive	± Abdominal distension Squirt/blast sign	Rectal biopsy (gold standard) look for aganglionosis and neural hypertrophy AXR Contrast enema to find narrow rectum and transition zone Anal manometry unreliable in infants classic finding is absence of rectoanal inhibitory reflex	Duhamel pull-through procedure: surgical resection of aganglionic intestinal segment and anastomosis of remaining intestine to anus Either in newborn period or staged if extensive aganglionosis	Most have normal/near-normal anorectal function Complications: fecal incontinence and constipation, postoperative enterocolitis (medical emergency if progresses to sepsis)
Cryptorchidism	Most common congenital abnormality of the GU tract 2-5% of term males most of these descend spontaneously by 6 mo of age 1% of males do not spontaneously descend Suspect in prematurity	Idiopathic Descent is mediated by INSL3 and testosterone Descent usually begins at 28 wk	Palpable testicle within inguinal canal or testicle which can be milked down into the scrotum (called retractile testis) Occasionally no palpable testis as it is intra-abdominal Consider other congenital abnormalities	Scrotal asymmetry Bi-annual testicular exam with palpation Distinguish truly undescended testis from retractile testis (which is "high" testis due to hyperactive cremasteric muscles)	Depends on age of presentation Older child: LH, FSH, Müllerian inhibiting substance, hCG stimulation test for gonadotropin production Infant: U/S, FSH, LH, karyotype, MIS, 17-hydroxy-progesterone If non-palpable: exam under anesthesia, exploratory laparoscopy	hCG to stimulate testosterone production and descent Orchidopexy especially if undescended by age 6 mo-2 yr	Orchidopexy Decreased risk of torsion and blunt trauma to testicle No effect on malignant potential of testicle Descent can preserve spermatogenesis if performed by 1 yr

Condition	Epidemiology and Risk Factors	Pathophysiology	Clinical Features and History	Physical Exam	Investigations	Treatment	Prognosis
Intussusception	Most common cause of bowel obstruction between 6-36 mo 26 in 100,000 newborns M:F=3:2 Pathologic lead points: enlarged Peyer's patches due to viral infections of the GI tract, polyps, Meckel's diverticulum CF, lymphoma and IBD may increase risk	Usually idiopathic Usually starts at ileocecal junction Telescoping of bowel into itself causing an obstruction and vascular compromise	Acute onset abdominal pain Episodic "colicky" pain Vomiting ± bilious Abdominal mass Currant-jelly stool suggests mucosal necrosis and sloughing	Abdominal exam Palpate for masses (especially sausage shaped upper abdominal mass) and tenderness Signs of bowel obstruction: distended abdomen Look for localized peritonitis which suggests transmural ischemia	AXR for signs of bowel obstruction or perforation U/S if suspect pathology	If peritonitis, consider operative management Non-operative management involves reduction via air contrast enema Operative reduction (open or laparoscopically) Resection of involved colon if failure to reduce or bowel appears compromised	10% recurrence rate If recurrent = more likely non-idiopathic If successfully reduced by enema in older children, allow 2 wk resolution of edema before performing SBFT to rule out pathologic lead points
Tracheoesophageal Fistula (TEF)	1 in 3000 to 1 in 4500 live births Typically occurs with esophageal atresia	Defect in the lateral septation of the foregut into the esophagus and trachea causing connection between the esophagus and trachea Associated anomalies in 50%: VACTERL association	Varies with type of fistula May have history of maternal polyhydramnios May present after several months (if no associated esophageal atresia) of non-bilious vomiting, coughing, cyanosis with feeds, respiratory distress, recurrent pneumonia, frothy bubbles of mucus in mouth, and nose that return after suctioning	Abdominal distention	X-ray: anatomic abnormalities, NG tube curled in pouch	Investigate for other congenital anomalies Early repair by surgical ligation to prevent lung damage and maintain nutrition and growth	Complications: pneumonia, sepsis, reactive airways disease Following repair: esophageal stenosis and strictures at repair site, GERD, and poor swallowing (i.e. dysphagia, regurgitation)
Inguinal Hernias	5% of all term newborns 2x risk and more likely bilateral if pre-term M:F=4:1 Low birth weight increases risk 1/5 inguinal hernias will become incarcerated if patient is <1 yr Incarceration is more common in females Associated with other conditions: androgen insensitivity, connective tissue diseases	All infant hernias are indirect: descent of intra-abdominal contents through the internal inguinal ring through a patent tunica vaginalis Inguinal hernia can be reducible, incarcerated (unreducible), or strangulated	Most common presentation: painless intermittent mass in groin, may also note extension into scrotum (scrotal mass in absence of inguinal mass is a hydrocele) If incarcerated: tender, vomiting, firm mass, erythema then cyanosis of mass may be noted	Palpate for "bag of worms" - suggests possible testicular varicocele Biannual testicular exam + palpation along inguinal canal to evaluate for any masses "Silk sign" palpable thickening of cord Mass palpated at external inguinal ring and reducible through inguinal canal into abdomen Must always try reduction to confirm that hernia is not incarcerated	Physical exam is gold standard U/S only if physical exam uncertain (e.g. in small infants where exam can be difficult)	Manual reduction in the ER to relieve acute symptoms For reducible hernia: repair within a few wk (if <1 yr) vs. elective repair (if >1 yr) For incarcerated hernia: repair immediately (emergency) Herniorrhaphy (laparoscopic or open) definitive treatment by reduction of herniated contents and high ligation of sac for indirect hernias	Risk of recurrence after surgical reduction <3%, higher if repair done in premature infants or if hernia was incarcerated/ strangulated

All inguinal hernias of infancy and childhood require repair at the earliest convenience; emergent repair if incarcerated/strangulated

Skin Lesions

Common Medications

Types	Drugs and Dosing
Antiemetics	dimenhydrinate (Gravol®) 25-50 mg PO/IV/IM q4-6 h prn prochlorperazine (Stemetil®) 5-10 mg PO/IV/IM BID-TID prn metoclopramide (Maxeran®) 10 mg IV/IM q2-3 h prn, 10-15 mg PO QID (30 min before meals and QHS) ondansetron (Zofran®) 4-8 mg PO q8 h prn granisetron (Kytril®) 1 mg PO BID (for nausea from chemotherapy/radiation)
Analgesics	acetaminophen ± codeine (Tylenol® #3/plain) 1-2 tabs q4-6 h PO/PR prn hydromorphone 1-2 tabs PO q4 h prn, 0.5-2 mg IV q3-4 h prn ibuprofen 200-400 mg PO q4-6 h prn morphine 2.5-10 mg IM/SC q4-6 h prn + 1-2 mg IV q1 h prn for breakthrough ketorolac (Toradol®) 30-60 mg IM/IV q6 h prn acetaminophen/oxycodone (Percocet®) 325/5 mg, 1-2 tabs PO q4-6 h prn
DVT Prophylaxis	heparin 5000 units SC BID; if cancer patient, then heparin 5000 units SC TID/BID dalteparin (Fragmin®) 5000 units SC daily enoxaparin (Lovenox®) 40 mg SC daily
Antidiarrheals	loperamide (Imodium®) 4 mg PO initially, then 2 mg PO after each loose stool up to 16 mg/d diphenoxylate + atropine (Lomotil®) 2 tabs/10 mL PO QID
Laxatives	sennosides (Senokot®) 1-2 tabs QHS docusate sodium (Colace®) 100 mg PO BID glycerine suppository 1 tab PR prn lactulose 15-30 mL PO QID prn milk of magnesia (MOM) 30-60 mL PO QID prn bisacodyl (Dulcolax®) 10-15 mg PO prn
Sedatives	zopiclone (Imovane®) 5-7.5 mg PO QHS prn lorazepam (Ativan®) 0.5-2 mg PO/SL QHS prn
Antibiotics	cefazolin (Ancef®) 1 g IV/IM on call to OR or q8 h – GP except *Enterococcus*, GN only *E. coli, Klebsiella*, and *Proteus* cefalexin (Keflex®) 250-500 mg PO QID – Listeria, GP except *Enterococcus*, GN only *E. coli, Klebsiella*, and *Proteus* ceftriaxone 1-2 g IM/IV q24 h broad coverage including Pseudomonas ampicillin 1-2 g IV q4-6 h – *Listeria*, GP (*Enterococcus*) except *Streptococcus* and *E. coli*, oral anaerobes
Bacteroides	gentamicin 3-5 mg/kg/d IM/IV divided q8 h; monitor creatinine, gentamicin levels GN including *Pseudomonas* ciprofloxacin 400 mg IV q12 h, 500 mg PO BID – GN including *Pseudomonas* metronidazole (Flagyl®) 500 mg PO/IV BID (500 mg PO TID for *C. difficile*) – anaerobes clindamycin 600-900 mg IV q8 h, 150-400 mg PO QID – GP except *Enterococcus*, anaerobes piperacillin/tazobactam 3.375 g IV q6 h – GP, GN, and anaerobes vancomycin 1g IV q12 h – GP and MRSA sulfamethoxazole/trimethoprim DS (Septra®) PO BID – GP, GN including *Nocardia*
Over-the-Counter Medications	bismuth subsalicylate (Pepto-Bismol®) 2 tabs or 30 mL PO q30 min-1 h up to 8 doses/d side effects: black stools, risk of Reye's syndrome in children ASA + citrate + bicarbonate (Alka-Seltzer®) 2 tabs in 4 oz water PO q4 h prn, max 8 tabs aluminum hydroxide + magnesium hydroxide (Maalox®) 10-20 mL or 1-4 tabs PO prn calcium carbonate (Tums®) 1-3 g PO q2 h prn calcium carbonate and magnesium hydroxide (Rolaids®) 2-4 tabs PO q1 h prn, max 12 tabs/d

Landmark General and Thoracic Surgery Trials

Trial Name	Reference	Clinical Trial Details
GROIN HERNIAS		
Outcomes of Laparoscopic vs. Open Repair of Primary Ventral Hernias	JAMA Surg 2013;148:1043-1048	**Title:** Outcomes of Laparoscopic vs. Open Repair of Primary Ventral Hernias **Purpose:** To compare outcomes of patients undergoing laparoscopic ventral hernia repair (LVHR) vs. open ventral hernia repair (OVHR). **Methods:** Single centre, retrospective study of 532 consecutive patients who underwent an elective primary ventral hernia (PVH) repair. The outcomes of the LVHR and OVHR were compared in terms of the primary outcomes of interest SSI, hernia recurrence, and bulging. **Results:** 79 patients with LVHR matched to 79 patients with OVHR with mesh with a median follow-up of 56 mo. LVHR was associated with fewer SSIs (7.6% vs. 34.1%) but more cases of bulging (21.5% vs. 1.3%) and port-site hernia (2.5% vs. 0.0%). No differences in recurrence were observed. **Conclusions:** LVHR is associated with fewer SSIs but more clinical cases of bulging and risk of developing a port-site hernia, compared to OVHR.
ACUTE CHOLECYSTITIS		
Laparoscopic cholecystectomy versus percutaneous catheter drainage for acute cholecystitis in high risk patients (CHOCOLATE): multicentre randomised clinical trial	BMJ 2018;363:k3965	**Title:** Laparoscopic cholecystectomy versus percutaneous catheter drainage for acute cholecystitis in high risk patients (CHOCOLATE): multicentre randomised clinical trial **Purpose:** To assess whether laparoscopic cholecystectomy is superior to percutaneous catheter drainage in high risk patients with acute calculous cholecystitis. **Methods:** 142 patients were randomized to either the laparoscopic cholecystectomy group or to the percutaneous catheter drainage group. **Results:** Although rate of death did not differ significantly between the laparoscopic cholecystectomy and percutaneous catheter drainage group, the complication rate in the laparoscopic cholecystectomy was significantly lower than that of the percutaneous catheter drainage (12% vs. 65%). The drainage group compared to the cholecystectomy group required reintervention at a higher rate, had recurrent biliary disease more frequently, and had longer lengths of stay. **Conclusions:** Laparoscopic cholecystectomy compared with percutaneous catheter drainage reduced the rate of major complications in high risk patients with acute cholecystitis.
BREAST CANCER		
10 Year Survival after Breast-Conserving Surgery Plus Radiotherapy Compared with Mastectomy in Early Breast Cancer in The Netherlands: A Population-Based Study	Lancet Oncol 2016;17(8):1158	**Title:** 10 Year Survival after Breast-Conserving Surgery Plus Radiotherapy Compared with Mastectomy in Early Breast Cancer in The Netherlands: A Population-Based Study **Purpose:** To evaluate 10 yr overall and breast cancer-specific survival after breast-conserving surgery plus radiotherapy compared with mastectomy in Dutch women with early breast cancer. **Methods:** Population study of women from the Netherlands Cancer Registry diagnosed with primary, invasive, stage T1-2, N0-1, M0 breast cancer, undergoing either breast-conserving surgery plus radiotherapy or undergoing mastectomy. **Results:** Breast-conserving surgery plus radiotherapy showed improved 10 yr overall and relative survival compared with mastectomy in early breast cancer, but 10 yr distant metastasis-free survival was improved with breast-conserving surgery plus radiotherapy compared with mastectomy in the T1N0 subgroup only, indicating a possible role of confounding by severity. **Conclusions:** Breast-conserving surgery plus radiotherapy is at least equivalent to mastectomy with respect to survival and may influence treatment decisions for patients.

CO	cardiac output	LOC	level of consciousness	PCI	percutaneous coronary intervention	TIA	transient ischemic attack
CrCl	creatinine clearance	LV	left ventricle			TCA	tricyclic antidepressant
						UI	urinary incontinence

Physiology and Pathology of Aging

Holistic Considerations for Aging

- aging results from the impact of the accumulation of a wide variety of molecular and cellular damage over time
- some of these changes are specific to the tissues of certain organs, whereas others occur over a number of organ systems
- normal age-related changes represent biologic processes common to everyone as they age; however, the rate and extent is extremely heterogeneous; thus, for the same chronological age, individuals may present with a different biological or phenotypic age or frailty level
- common geriatric syndromes are associated with advanced age. Often, there are many factors contributing to certain geriatric syndromes, such as falls and frailty, as opposed to a single cause

The table below outlines the physiological changes that occur with aging and their organ specific impacts. In addition, it outlines pathological conditions occurring in greater frequency in older adults. Physiological changes may predispose older adults to pathological conditions; however, unlike normal changes of aging, not all older adults will develop pathological changes associated with aging.

Table 1. A Systems-Based Analysis of Potential Changes That Can Occur with Aging

System	Physiological Changes	Impact of Physiologic Changes (Normal Aging)	Pathological Changes Occurring Frequently with Older Adults
Neurologic	Decreased brain mass and cerebral blood flow Increased white matter changes Reduced number of neurons Reduced action potential speed	Mild impact on working memory and processing speed Reduced sleep time Reduced fine-motor control Reduced reflex response	Insomnia, neurocognitive disorders (e.g. Vascular dementia, Alzheimer's disease), stroke
Senses	Eyes: thickened lenses, reduced pupil diameter, increased lipid infiltrates, decreased lacrimal gland secretion ENT: reduced saliva, atrophied hair cells, reduced cochlear and inner ear neurons, reduced ossicular articulation	Eyes: reduced visual acuity, dark adaptation ENT: reduced sense of smell and taste, reduced detection of higher frequency sounds (presbycusis – sensorineural hearing loss), reduced vestibular function	Increased glaucoma, cataracts, macular degeneration, tinnitus, vertigo, oral dryness
Cardiovascular	Increased left ventricular thickness and stiffness Increased vascular resistance Reduced pacemaker cells Decreased baroreflex and autonomic reflexes Decreased vessel elasticity, cardiac myocyte size and number, β-adrenergic responsiveness	Increased sBP, decreased dBP, HR, CO, wide pulse pressure Heart and blood vessels less responsive to physiological stress	Increased atherosclerosis, CAD, MI, CHF, HTN, arrhythmias, orthostatic hypotension
Respiratory	Increased tracheal cartilage calcification, mucous gland hypertrophy Decreased elastic recoil, increased residual volume, reduced vital capacity, forced expiratory volume Reduced chest wall compliance	Decreased arterial partial pressure of oxygen, decreased exercise tolerance, decreased pulmonary reserve	Increased COPD, pneumonia, pulmonary embolism
Gastrointestinal	Increased intestinal villous atrophy Decreased esophageal peristalsis, gastric acid secretion, liver mass, hepatic blood flow, calcium, and iron absorption	Reduced B_{12}, calcium and iron absorption	Increased dysphagia, cancer, diverticulitis, constipation, fecal incontinence, hemorrhoids, intestinal obstruction, malnutrition, weight loss
Renal and Urologic	Decreased renal mass and number of renal tubules and glomeruli, reduced renal blood flow Reduced nerve density and diminished detrusor function in bladder Reduced diurnal antidiuretic hormone	Decreased eGFR and concentration ability of kidney Increased urine pH Reduced hydroxylation of vitamin D Proteinuria Urinary frequency and urgency Nocturia	Increased urinary incontinence and urgency, BPH, prostate cancer, pyelonephritis, nephrolithiasis, UTI, testicular atrophy, urinary retention

Functional Assessment (ADLs and IADLs)

ADLs: ABCDE-TT	IADLs: SHAFT-TT
Ambulating	**S**hopping
Bathing	**H**ousework
Continence	**A**ccounting/Managing finances
Dressing	**F**ood preparation
Eating	**T**ransportation
Transferring	**T**elephone
Toileting	**T**aking medications

Comprehensive Geriatric Assessment for Older Adults Admitted to Hospital
Cochrane DB Syst Rev 2017;CD006211
Purpose: To determine whether CGA can improve care provided to older adults admitted to hospital.
Results/Conclusions: Inpatient CGA increases likelihood that patients will be alive in their own homes at 3-12 mo follow-up (risk ratio (RR) 1.06, 95% CI 1.01-1.10), decreases the likelihood that patients will be admitted to a nursing home at 3-12 mo (RR 0.80, 95% CI 0.72-0.89), and results in little or no difference in dependence (RR 0.97, 95% CI 0.89-1.04). Evidence for cost-effectiveness of performing a CGA in older adults admitted to hospital is inconclusive due to imprecision and inconsistency among studies.

Comprehensive Geriatric Assessment for Community-Dwelling, High-Risk, And Frail Older People
Cochrane DB Syst Rev 2022;CD0012705
Purpose: Appraisal of the effectiveness of using the CGA for community-dwelling, high-risk, and frail older adults.
Results/Conclusions: CGA resulted in no difference in mortality during median follow-up at 12 mo (RR 0.88 95% CI 0.76-1.02), and concurrently no difference in nursing home admission (RR 0.93, 95% CI 0.76 to 1.14). CGA may decrease the risk of unplanned hospital admission over 14 mo of follow-up (RR 0.83 95% CI 0.70 to 0.99).

Table 1. A Systems-Based Analysis of Potential Changes That Can Occur with Aging

System	Physiological Changes	Impact of Physiologic Changes (Normal Aging)	Pathological Changes Occurring Frequently with Older Adults
Reproductive	Decreased androgen, estrogen, sperm count, vaginal secretion Decreased ovary, uterus, vagina, and breast size		Increased breast and endometrial cancer, cystocele, rectocele, atrophic vaginitis
Endocrine	Increased **NE**, **PTH**, insulin, vasopressin Decreased thyroid and adrenal corticosteroid secretion	Impaired stress response	Increased **DM**, hypothyroidism
MSK	Increased calcium loss from bone Decreased muscle mass/sarcopenia, cartilage, synovial fluid lubrication	Decreased strength (note: reduced motor strength on neurological examination is not expected) Joint stiffness and reduced joint capsule flexibility	Increased arthritis, bursitis, osteoporosis, muscle weakness with gait abnormalities, polymyalgia rheumatica
Integumentary	Atrophy of sebaceous and sweat glands Decreased epidermal and dermal thickness, dermal vascularity, melanocytes, collagen synthesis, elastin synthesis	Increased skin laxity, wrinkles, and skin stiffness, and easy bruising	Increased lentigo, cherry hemangiomas, pruritus, seborrheic keratosis, pressure injuries, skin cancer, onychomycosis, senile purpura, xerosis cutis
Immunologic	Decreased antigen-antibody affinity, decreased efficacy of neutrophils and macrophages, decreased numbers of B and T cells (excluding memory B and memory T cells)	Reduced response to new pathogens, reduced response to immunizations and increased need for boosters Blunted fever response and atypical presentation of infections which may lead to delayed care	Increased susceptibility to malignancies, infections, and autoimmune conditions
Psychiatric	Decreased processing speed, cognitive flexibility, visuospatial perception, working memory, and divided attention Loss of synaptic plasticity		Increased depression, dementia, delirium, suicidality, anxiety, sleep disruption

Framework for the Approach to the Older Adult

History: A Brief Geriatric Screen Using "The 5 M's Framework"

- **M**ind: consider mentation, dementia, delirium, and depression
  - consider more validated screening when concerns are raised from patients and/or family members/caregivers
  - consider asking if patients suffer from chronic pain
- **M**obility: observe for impaired gait and balance and consider fall injury prevention strategies
  - consider evidenced-based ways to reduce injuries: exercise, vision evaluation and treatment, home safety assessment, occupational therapy support, calcium and vitamin D supplementation
- **M**edications: monitor for polypharmacy, practice optimal prescribing, consider de-prescribing where possible, check adherence, check medication understanding from patient perspective, be cautious of adverse medication effects
- **M**ultimorbidity: use a bio-psycho-social approach to assess a patient's comorbidities
- **M**atters most: explore values and priorities (maintaining independence, preventing adverse events, optimizing comfort, prioritizing prolonged life)

Focused Geriatric Physical Exam

- general and vital signs: weight (signs of cachexia, unintentional weight loss), height (reduction may indicate vertebral compression fractures or osteoporosis), orthostatic vitals (blood pressure and heart rate)
- head and neck: test visual acuity, in-office hearing screen (whisper test), dentition, denture fit, lymphadenopathy, and neck masses
- cardiac: auscultate for arrhythmias, murmurs, extra heart sounds
- respiratory: auscultate, observe for SOB
- peripheral vascular exam: assess for arterial or venous insufficiency, inspect for edema and ulcers, palpate for diminished peripheral pulses
- dermatologic: look for premalignant/malignant lesions especially on sun-exposed areas, examine for pressure injuries in who are immobile, foot wounds in those with diabetes, neuropathy and peripheral vascular disease, examine for unexplained bruises or signs of elder abuse
- MSK: determine range of motion focused joint exam based on history
- gait: check footwear and fit of gait aids, assess gait systematically, Romberg for balance, and sit-to-stand test. Consider additional balance tests such as pull-back test, forward reach, tandem stance and gait
- neurologic: examine cranial nerves, tone, reflexes, sensation. Assess for signs of parkinsonism, tremor, and perform cerebellar testing

Presentations in Older Adults

Constipation

• see Gastroenterology, G28

Definition
• Rome IV Diagnostic Criteria (≥2 must be present in ≥1/4 of bowel movements for ≥3 mo with symptom onset ≥6 mo prior):
  ▪ straining
  ▪ hard stools
  ▪ sensation of incomplete evacuation
  ▪ use of manual maneuvers to facilitate defecation
  ▪ sensation of anorectal obstruction/blockage
  ▪ <3 bowel movements per wk
  ▪ patients must meet both of the following criteria:
    ◆ loose stool rarely present without the use of laxatives
    ◆ does not meet Rome IV criteria for IBS

Epidemiology
• chronic constipation increases with age (up to 1/3 of patients >65 yr experience constipation and 1/2 of patients >80 yr)
• in the elderly, chronic constipation may present as fecal impaction and overflow diarrhea

Etiology
• neurological: dementia, parkinsonism, autonomic dysfunction, spinal cord injuries
• metabolic: hypercalcemia, hypothyroidism, hypokalemia, hypomagnesemia
• nutritional: low dietary fibre, dehydration
• cancer/cancer related: colorectal cancer, post-radiation, tumour compression or bowel obstruction
• bowel related: IBS, IBD, strictures
• systemic diseases: systemic sclerosis, amyloidosis
• drugs associated with constipation:
  ▪ opioids
  ▪ psychotropics (e.g. antipsychotics, TCAs)
  ▪ anticholinergics (e.g. dimenhydrinate, diphenhydramine, TCAs, antimuscarinics for urinary incontinence)
  ▪ calcium channel blockers
  ▪ diuretics
  ▪ supplements (e.g. iron, calcium)
  ▪ immobility and non-optimal positioning)

Pathophysiology
• impaired rectal sensation (increased rectal distention required to stimulate the urge to defecate)
• colorectal dysmotility

Alarm Symptoms
• fever
• hematochezia, blood in stool, positive fecal occult blood test / fecal immunochemistry test
• severe nausea/vomiting, severe abdominal pain
• abdominal/rectal mass
• obstipation
• new changes in bowel habits when age >50 yr
• unexplained anemia or iron deficiency on blood work
• acute onset
• severe constipation that is unresponsive to treatment
• weight loss >5kg in previous 6 mo
• change in stool caliber
• family history of colon cancer

Treatment
• non-pharmacological
  ▪ bowel training
  ▪ increase fibre intake to 20-30g per day (note: bulking agents, e.g. psyllium, Metamucil®, may worsen constipation in some), especially if insufficient fluid intake)
  ▪ ensure adequate fluid intake
  ▪ increase physical activity and optimize positioning for defecation (seated position, with knees at or above the level of hips)
• pharmacological
  ▪ see Figure 1
  ▪ discourage chronic laxative use
  ▪ review medication regime, reduce dosages or substitute
• see *Common Medications, GM*18

A Double-Blind, Placebo-Controlled Study of Prucalopride in Elderly Patients with Chronic Constipation
Neurogastroenterol Motil 2010;22(9):991-98
Purpose: To assess the efficacy, safety, and tolerability of prucalopride in chronically constipated elderly patients.
Results/Conclusions: The prucalopride dose range tested (1-4 mg daily) is effective at promoting bowel movements, minimizing constipation-associated symptoms, and improving quality of life. It is safe and well-tolerated in elderly patients with chronic constipation.

The Effect of Probiotics as a Treatment for Constipation in the Elderly: A Systematic Review
Arch Gerontol Geriatr 2017;71:142-49
Purpose: Evaluate the effectiveness of probiotics in treating elderly constipation, as an alternative to traditional drug-based treatments.
Results/Conclusions: Analysis of placebo-controlled RCTs suggested that administration of probiotics significantly improved constipation in the elderly by 10-40% compared to placebo. Further trials are required to elucidate optimal protocols of probiotic treatment regimens.

Treatment of Constipation in Older People
CMAJ 2013 May 14;185(8):663–67
Purpose: To summarize the treatments for constipation in older people and provide a guide to the assessment and management of constipation in older adults.
Results/Conclusions: The efficacy and safety of treatments for constipation in older people is presented and a step-wise approach to constipation in older adults is proposed.

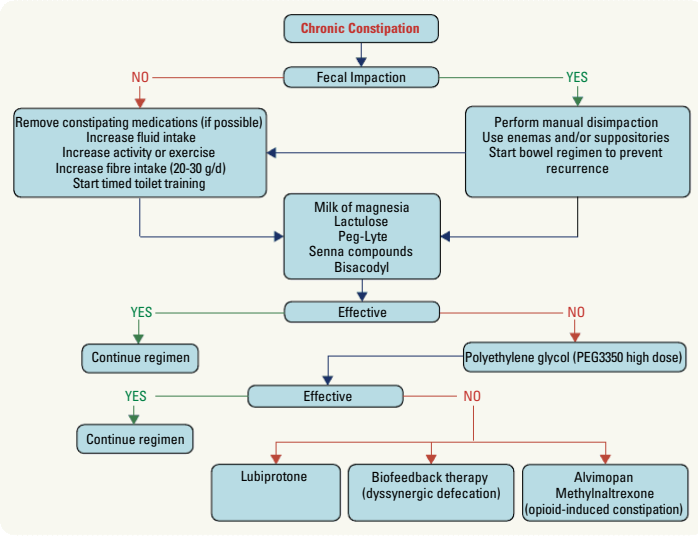

Figure 1. Treatment algorithm for the management of chronic constipation in older adults
Adapted from: Clin Interv Aging 2010;5:163-171

Delirium

• see Psychiatry, PS23 and Neurology, N21

Definition
• acute and potentially reversible disturbance in cognition, attention, or level of consciousness

Epidemiology
• delirium is especially common among patients in the ICU setting, postsurgical setting, and general medical setting
  ▪ up to 25% of patients after elective surgery
  ▪ 50% of patients after high-risk procedures (e.g. cardiac surgery, hip-fracture repair)
  ▪ up to 75% of mechanically ventilated patients in the ICU
• can affect all ages but is especially common in hospitalized older adults
  ▪ one-third of general medical patients >70 yr have delirium

Screening/Diagnostic Tools
• screened using the Confusion Assessment Method: delirium likely if 1 + 2 and either 3 or 4 are present
  1. acute onset and fluctuating course
  2. inattention
  3. disorganized thinking
  4. altered level of consciousness
• classified as: hyperactive, hypoactive, or mixed

Differential Diagnosis
• 3Ds (dementia, delirium, depression) can present with overlapping cognitive changes
• seizure
• stroke

Assessment
• history should ascertain patient's baseline cognitive function from informant
• ascertain course in hospital, obtain course of confusion with allied health
• review MARs for medications received in hospital, compare to home medications)
• substance use history, day of last use
• history and physical exams to assess for precipitating etiologies (DIMES)

Delirium in Older Persons: Advances in Diagnosis and Treatment
JAMA 2017;318(12):1161-74
Purpose: To provide overview of current state of diagnosis and treatment of delirium and identify promising areas for future research
Methods: Controlled vocabulary and keyword terms were searched in Ovid MEDLINE, Embase and the Cochrane Library with focus on studies conducted in elderly populations.
Results: 127 articles met inclusion criteria. High sensitivity and specificity brief screening tools and measures of delirium severity contribute to ability to diagnose, treat, risk stratify, and prognosticate patients. Nonpharmacologic approaches are effective for delirium prevention and recommended for delirium treatment. Pharmacologic treatment (antipsychotics, other sedatives) for agitation should only be used if the patient is at safety risk to themselves or others or is impeding medical treatment of the underlying cause.
Conclusion: Better screening and diagnosis of delirium leads to better risk stratification. Nonpharmacologic approaches of delirium prevention are effective, whereas pharmacological management of delirium is controversial.

Antipsychotics for Treating Delirium in Hospitalized Adults: A Systematic Review
Ann Intern Med 2019;171:485-95
Purpose: Evaluate with current literature the risks and benefits of antipsychotics in delirium management for hospitalized adults.
Study Selection: RCTs of antipsychotic vs. placebo or another antipsychotic, as well as prospective observational studies that report harms, are selected through searches on PubMed, Embase, CENTRAL, CINAHL, and PsycINFO from inception to July 2019. The review selected 16 RCTs and 10 observational studies of hospitalized adults.
Data Synthesis: No significant difference in sedation, delirium, hospital length-of-stay, or mortality between haloperidol and second-generation antipsychotics vs. placebo. No difference in mortality in direct comparisons between second-generation antipsychotics. While short term use of antipsychotics for delirium management does not appear to pose neurological harm, it poses a risk of QT prolongation.
Conclusion: The current evidence does not support the routine use of haloperidol or second-generation antipsychotics in delirium management for adult inpatients.

A Multicomponent Intervention to Prevent Delirium in Hospitalized Older Patients
NEJM 1999;340:(9):669-676
Purpose: To evaluate the effectiveness of a multicomponent strategy for the prevention of delirium.
Conclusion: The multicomponent intervention lead to significant reductions in the number and duration of episodes of delirium in hospitalized older patients.

Assess for Precipitants "DIMES"

- **D**: drugs (consider prescribed, over the counter, overdose, intoxication, and withdrawal) (e.g. alcohol, benzodiazepine, nicotine, cannabis))
- **I**: infection (consider urinary tract, lungs, skin, bacteremia, CNS)
- **M**: metabolic disturbances (consider fluid imbalances, electrolyte abnormalities (hyponatremia, hypercalcemia), nutritional deficiencies (B12, B1), hepatic encephalopathy, hypothyroidism/ hyperthyroidism
- **E**: environmental (room changes, lighting, noise)
- **S**: structural insults (cardiovascular, CNS, pulmonary, GI, foley catheter, urinary retention, constipation)

Work-Up

- work-up is not universal and depends on possible causes based on history and physical exam:
  - drugs: toxicology screen, therapeutic drug-levels (Dilantin, carbamazepine, digoxin)
  - infection, infarction, inflammation: CBC, urinalysis, urine culture, blood culture, CXR, ECG, troponin, creatinine kinase
  - metabolic: basic and extended electrolytes, vitamin B12, TSH, LFT, toxicology screen, glucose, arterial blood gas/venous blood gas, creatinine
  - structural: neuroimaging, abdominal x-ray

Delirium Prevention in Older Adults

- orientation: orient to date/time, clocks and calendars visible in room
- cognitive stimulation: therapeutic activities, family visitation and education
- sleep enhancement: reduce interruptions at night, dim light., avoid sleep aids, stimulation during the day
- early and safe mobilization
- adequate nutrition and hydration: monitor fluid status, encourage oral hydration and nutrition, meal set-up and feeding assistance, use of dentures, up in chair to eat when possible
- optimal prescribing and avoid precipitating medications: multimodal pain control to limit opioid use, avoiding sedatives, anticholinergics. and antipsychotics, monitor for interactions and adverse events
- correction of sensory deficits: bring and use glasses & hearing aids, amplification devices
- reduce, monitor for and address acute insults: remove foleys as soon as possible, monitor for urinary retention and constipation, spirometry

Table 2. Differentiating the Three Ds of Cognitive Impairment

	Dementia	Delirium	Depression
Onset	Gradual or step-wise decline	Acute (hours to days)	Subacute (weeks to months)
Duration	Months to years	Days to weeks, may take months for deficits to fully resolve	Variable
Natural History	Progressive, usually irreversible, gradual loss of ADL/IADLs	Fluctuating, reversible High morbidity/mortality in very old Increased risk of subsequent development of dementia	Usually reversible May be recurrent
Level of Consciousness	Normal	Fluctuating Hyperactive/alert or depressed	Normal
Attention	Intact initially	Impaired	Possible reduced concentration
Orientation	Intact initially	Impaired, fluctuating	Intact
Behaviour	Disinhibition, personality change	Psychomotor agitation or retardation	Importuning, self-harm/suicide
Psychomotor	Normal	Fluctuates between extremes	Slowing
Sleep-Wake Cycle	Fragmented sleep at night	Reversed sleep-wake cycle	Early morning awakening
Mood and Affect	Can be unchanged Some may develop apathy, depression, anxiety, labile affect	Anxious, irritable, fluctuating	Depressed, flat affect, stable
Cognition	Gradually progressive decline in cognition Domains impacted depend on dementia subtype	Fluctuation Inattention predominant	Impaired concentration
Memory Loss	Short term memory impairment is predominant in Alzheimer's dementia	May have impaired short-term memory	Possible impairment in episodic memory

Evidence on Management of Delirium:

- see "Antipsychotics for Treating Delirium in Hospitalized Adults: A Systematic Review"
- see "Delirium in Older Persons: Advances in Diagnosis and Treatment"

Elder Abuse Prevalence in Community Settings: A Systematic Review and Meta-Analysis
Lancet Glob Health 2017;5:147-56
Purpose: Since quantitative syntheses of elder abuse prevalence are rare, the study aimed to quantify and understand prevalence variation at global and regional levels.
Methods: A comprehensive search strategy from 14 databases was employed to identify elder abuse prevalence studies in the community, published from inception to June 2015. Subgroup analysis and meta-regression were used to explore heterogeneity.
Results: 52 of the 38544 initially identified studies were eligible for inclusion, all of which were geographically diverse (28 countries). The pooled prevalence estimates were 11.6% for psychological abuse, 6.8% for financial abuse, 4.2% for neglect, 2.6% for physical abuse, and 0.9% for sexual abuse. Significant heterogeneity was found in associations with overall prevalence estimates, including sample size, income classification, and method of data collection, but not with gender.
Conclusion: Elder abuse is a neglected public health priority, especially compared with other types of violence. Elder abuse seems to affect 1 in 6 older adults worldwide, a figure totaling 141 million people.

Elder Abuse Screening Tools: A Systematic Review
J Adult Prot 2017;19:368-79
Context and Purpose: With high rates of morbidity and mortality, along with deleterious psychological harms, elder abuse is often difficult to detect. This study seeks to review currently available elder abuse screening tools.
Results: 11 of 34 full text studies met inclusion criteria and were included in the final analysis. Of these, three studies reported sensitivity and specificity while the remainder reported validity and reliability testing. Ultimately, the clinical environment will dictate the choice of screening tool.
Limitations: Variations in tool qualities and characteristics led to challenges in data synthesis. A further challenge was the lack of a gold standard screening tool for elder abuse, for evaluation of heterogeneity.
Conclusion: Research on screening tools remains hard-pressed in distinguishing those assessing suspected or actual elder abuse and those assessing risk factors for abuse. Although screening tools carry inherent limitations, they can be used to guide further assessments for an objective diagnosis.

Elder Abuse

Definition
- includes physical abuse, sexual abuse, emotional/psychological abuse, financial exploitation, and neglect
- elder abuse is a criminal offence under the Criminal Code of Canada and in most U.S. states

Epidemiology
- in Canada in 2019, almost 4518 seniors were victims of police-reported family violence
- the perpetrators of family violence against seniors were identified to be their grown child (34% of cases) and their spouses (26% of the cases)
- in older adults ≥60 yr, elder abuse is estimated to occur in 10% of patients
- insufficient evidence to include/exclude screening in the Periodic Health Exam

Risk Factors

Table 3. Risk Factors for Elder Abuse

Situational Factors	Social (e.g. isolation)
Victim Characteristics	Physical or emotional dependence on caregiver
	Lack of close family ties
	History of family violence
	Dementia or recent deterioration in health
Perpetrator Characteristics	Related to victim
	Dependency on older adult (e.g. financial dependency)

Screening Tools
- Elder Abuse Suspicion Index© (EASI©): a six-item questionnaire to raise a physician's level of suspicion for elder abuse and promote referral of possible victims for further assessment by social services

Management
- assess patient's decision-making capacity regarding any proposed intervention
- address imminent safety
- consider referral to local resources (home care, respite agencies, shelters, legal services, police services, government-supported elder abuse consultants)
- create emergency safety plan
- offer assistance with reporting abuse
- in Ontario, reporting elder abuse is mandatory when an older adult resides in a Long-term Care Home or a Retirement Home

Falls

Definition
- an event resulting in a person coming to rest inadvertently on a lower level, other than as a consequence of sudden paralysis, epileptic seizure, or overwhelming external force

Epidemiology
- approximately 20-30% of older adults ≥65 yr fall each year in Canada, prevalence increases with age
  - falls resulting in injury (e.g. broken/fractured bones, sprain/strain, concussion) were more likely to occur in women than men
  - 25% associated with serious and 1/3 of hospitalizations were associated with hip fractures
  - more than 1/3 of older adults are admitted to long-term care after hospitalization

Etiology
- intrinsic factors
  - age-related changes and diseases associated with aging: MSK (arthritis, muscle weakness), sensory (visual, proprioceptive, vestibular), cognitive (depression, dementia, delirium, anxiety), cardiovascular (CAD, arrhythmia, MI, low BP), neurologic (stroke, decreased LOC, gait disturbances/ataxia), and metabolic (glucose, electrolytes)
  - orthostatic/syncopal
  - acute illness, exacerbation of chronic illness
- extrinsic factors
  - environmental (e.g. home layout, slippery surfaces, overcrowding, new environments)
  - side effects of medications, polypharmacy (>4 medications), and substance misuse (e.g. alcohol misuse)
- situational factors
  - activities (e.g. rushing to the toilet, walking while distracted)

History and Physical Exam
- falls history: pre-fall symptoms (chest pain, syncope, presyncope, palpitations), infectious symptoms, mechanisms, loss of consciousness, head trauma, neck/cervical spine trauma, post-fall (how long were they on the ground, who helped them up, post-fall confusion or amnesia)
- extended history: previous falls and/or gait instability, intrinsic, extrinsic and situational factors, associated symptoms, medication and alcohol use, change in medications

EASI©
For each of the 6 items below, indicate "yes," "no," or "did not answer." A response of "yes" on 1+ of questions 2-6 is concerning for elder abuse
Q.1-Q.5 asked of patient; Q.6 answered by doctor (Within the last 12 mo)

1 Have you relied on people for any of the following: bathing, dressing, shopping, banking, or meals?
2 Has anyone prevented you from getting food, clothes, medication, glasses, hearing aids or medical care, or from being with people you wanted to be with?
3 Have you been upset because someone talked to you in a way that made you feel shamed or threatened?
4 Has anyone tried to force you to sign papers or to use your money against your will?
5 Has anyone made you afraid, touched you in ways that you did not want, or hurt you physically?
6 Doctor: Elder abuse may be associated with findings such as: poor eye contact, withdrawn nature, malnourishment, hygiene issues, cuts, bruises, inappropriate clothing, or medication compliance issues. Did you notice any of these today or in the last 12 mo?

Yaffe MJ, Wolfson C, Lithwick M, et al. Development and validation of a tool to assist physicians' identification of elder abuse: The Elder Abuse Suspicion Index (EASI ©). J Elder Abuse Negl 2008;20(3):276-300.

Key Clinical History Findings in Falls Evaluation

SPLATT
Symptoms
Previous falls
Location of falls
Activity at the time of fall
Time of fall
Trauma

Impact of Medication Classes on Falls Risk in Geriatrics (Odds Ratios)

Antidepressants (1.68)
Neuroleptics/antipsychotics (1.59)
Benzodiazepines (1.57)
Sedatives/hypnotics (1.47)
Antihypertensive agents (1.24)
NSAIDs (1.21)
Diuretics (1.07)
β-blockers (1.01)

Meta-analysis of the impact of 9 medication classes on falls in elderly persons. Arch Intern Med 2009:169(21):1952-1960

- have a witness present, if possible, for interview
- physical exam: orthostatic BP, injury screen, cardiac, visual acuity, examination of feet and footwear, gait assessment, Timed Up-and-Go Test, MSK, neurologic

Investigations

- CGA to identify potential causes
- investigations should be tailored based on history and physical examination. They might consist of:
  - CBC, electrolytes, BUN, creatinine, glucose, Ca^{2+}, TSH, vitamin B_{12}, urinalysis, cardiac enzymes, ECG, CT head (as directed by history and physical), coagulation profile
- bone densitometry (dual-energy x-ray absorptiometry) for osteoporosis screening in all women and men >65 yr

Interventions

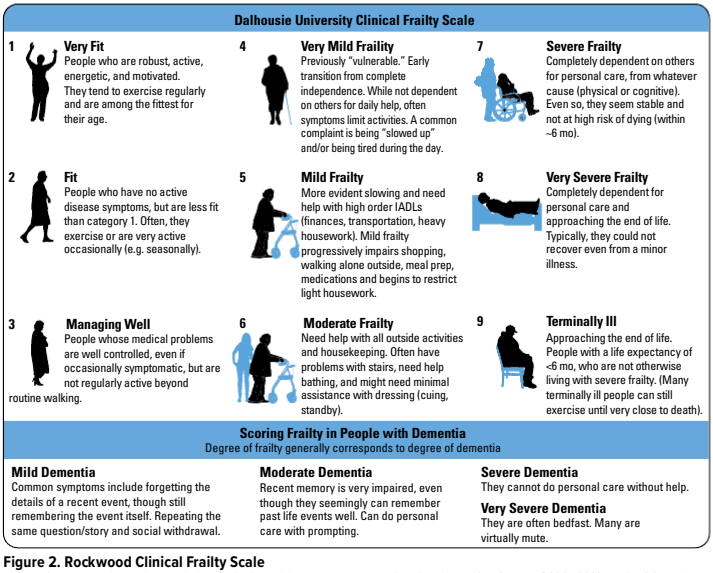
- interventions depend on the identified intrinsic and extrinsic risk factors. First address any acute illness that precipitated the fall and treat any injuries or complications
- multidisciplinary, multifactorial, health and environmental risk factor assessment, and intervtion programs in the community
- muscle strengthening, balance retraining (e.g. Tai Chi) with appropriate assistive devices, and group exercise programs
- home hazard assessment and modification with potential for collaboration with occupational therapy (e.g. remove loose rugs and tripping hazards, add shower bars and stair railing, improve lighting)
- fitted gait aid
- taper or gradual discontinuation of psychotropic medication
- postural hypotension, heart rate, and rhythm abnormalities management
- eyesight (cataract surgery) and footwear optimization
- compression socks if venous stasis edema
- hip protectors
- prescription of vitamin D 1000 IU daily if vitamin D stores are low
- optimization of daily calcium intake via diet or calcium supplementation calcium in diet with 1200 mg of supplemental calcium advised if osteoporosis is a risk

Will My Patient Fall?
JAMA 2007;297:77-86
Purpose: To identify the prognostic value of risk factors for future falls among older patients.
Study Selection: Meta-analysis of prospective cohort studies of risk factors for falls.
Results: 18 studies were included. Clinically identifiable risk factors were identified across 6 domains: orthostatic hypotension, visual impairment, impairment of gait or balance, medication use, limitations in ADLs or IADLs, and cognitive impairment. The estimated pretest probability of falling at least once in any given yr for individuals ≥65 yr was 27% (95% CI 19-36%). Patients who have fallen in the past year are more likely to fall again (LR 2.3-2.8). Best predictors of future falls were disturbances in gait or balance (LR 1.7-2.4), while visual impairment, impaired cognition, and medication were not reliable predictors.
Conclusions: Screening for risk of falling during the clinical examination begins with determining if the patient has fallen in the past yr. For patients who have not previously fallen, screening consists of an assessment of gait and balance. Patients who have fallen or who have a gait or balance problem are at higher risk of future falls.

Frailty

Definition

- frailty: clinically-recognizable state of decreased reserve in older adults with increased vulnerability to acute stressors resulting from functional decline across multiple physiologic systems
- functional decline: progressive limitation in the ability to carry out basic functional activities
- frailty is associated with higher risk of in-hospital death, adverse events, length of stay, hospital re-admission, and newly dependent at discharge following critical illness



Dalhousie University Clinical Frailty Scale
1
Very Fit
People who are robust, active, energetic, and motivated. They tend to exercise regularly and are among the fittest for their age.
2
Fit
People who have no active disease symptoms, but are less fit than category 1. Often, they exercise or are very active occasionally (e.g. seasonally).
3
Managing Well
People whose medical problems are well controlled, even if occasionally symptomatic, but are not regularly active beyond routine walking.
4
Very Mild Frailty
Previously "vulnerable." Early transition from complete independence. While not dependent on others for daily help, often symptoms limit activities. A common complaint is being "slowed up" and/or being tired during the day.
5
Mild Frailty
More evident slowing and need help with high order IADLs (finances, transportation, heavy housework). Mild frailty progressively impairs shopping, walking alone outside, meal prep, medications and begins to restrict light housework.
6
Moderate Frailty
Need help with all outside activities and housekeeping. Often have problems with stairs, need help bathing, and might need minimal assistance with dressing (cuing, standby).
7
Severe Frailty
Completely dependent on others for personal care, from whatever cause (physical or cognitive). Even so, they seem stable and not at high risk of dying (within ~6 mo).
8
Very Severe Frailty
Completely dependent for personal care and approaching the end of life. Typically, they could not recover even from a minor illness.
9
Terminally Ill
Approaching the end of life. People with a life expectancy of <6 mo, who are not otherwise living with severe frailty. (Many terminally ill people can still exercise until very close to death).
Scoring Frailty in People with Dementia
Degree of frailty generally corresponds to degree of dementia
Mild Dementia
Common symptoms include forgetting the details of a recent event, though still remembering the event itself. Repeating the same question/story and social withdrawal.
Moderate Dementia
Recent memory is very impaired, even though they seemingly can remember past life events well. Can do personal care with prompting.
Severe Dementia
They cannot do personal care without help.
Very Severe Dementia
They are often bedfast. Many are virtually mute.

Figure 2. Rockwood Clinical Frailty Scale
Adapted from and reprinted with permission: Geriatric Medicine Research, Dalhousie University, Halifax, Canada. ©2005-2020 Version 2.0. All rights reserved

MODELS OF FRAILTY

Physical Frailty (PF) Phenotype (Fried et al.)
- Frail: ≥3 criteria; at-risk or pre-frail = 1 or 2 criteria
  1. shrinking: unintentional weight loss (baseline: >=10 lbs or 5% total body weight lost in prior yr)
  2. weakness: grip strength in lowest 20% (by gender, BMI)
  3. poor endurance: as indicated by self-report of exhaustion
  4. slowness: walking time/15 feet in slowest 20% (by gender, height)
  5. low activity: kcals/wk in lowest 20% (males: <383 kcals/wk, females: <270 kcals/wk)

Cumulative Deficit Approach (Rockwood et al.)
- balance between assets (e.g. health, attitudes, resources, caregiver) and deficits (e.g. illness, disability, dependence, caregiver burden) that determines whether a person can maintain independence in the community
- frailty index: number of deficits present/number of deficits possible

Etiology
- multifactorial: dysregulated immune, endocrine, stress, and energy response systems lead to development of clinical frailty

Table 4. Etiologies of Frailty

Etiology	Mechanism
Physiologic Changes with Aging	Sarcopenia (age-related loss of skeletal muscle and strength), decreased mass and increased stiffness of organs, decreased reserve capacity of systems
Immune System	Elevated levels of circulating interleukin-6, C-reactive protein, white blood cells, and monocytes associated with skeletal muscle decline Elevated clotting markers (factor VIII, fibrinogen, D-dimer) upregulates clotting cascade Chronic inflammation
Endocrine System	Sarcopenia via: Decreased growth hormone and IGF-1 Increased cortisol levels Decreased DHEA-S Decreased 25 (OH) vitamin D
Stress dysregulation of autonomic nervous system	
Age-related changes in renin-angiotensin system and mitochondria likely impact sarcopenia and inflammation	

Evidence-based Approach to the Frail Older Patient
- CGA
  - includes: past medical history, medications, allergies, social history, function, and geriatric review of systems (cognition, mood, sleep, pain, nutrition, falls, continence, vision/hearing, skin, and safety)
  - physical exam
  - investigations: CBC, electrolytes, TSH, vitamin B12, vitamin D, LFTs, extended electrolytes
- management
  - CGA to tailor management of geriatric syndromes (e.g. falls, cognitive impairment, incontinence)
  - physical activity programs, nutritional optimization, multicomponent interventions
  - interdisciplinary primary care
  - referral to Acute Care for Elders (ACE) unit for inpatients who are living with frailty
  - medication optimization
  - caregiver support

Immobility

Definition
- limitation in independent and voluntary physical movement of the body or one or more lower
- extremities associated with disability, increased frailty and risk of falls, decreased quality of life

Etiology and Risk Factors
- multifactorial; functional assessment in addition to comprehensive history-taking and interdisciplinary approach to care is crucial
- psychological
  - fear of falling, motivation, depression
- physical changes
  - MSK disorders: history of hip or leg fractures, osteoporosis, arthritis
  - neurologic disorders: stroke, Parkinson's disease, severe dementia, neuropathies
  - cardiovascular: CHF, angina secondary to CAD, claudication secondary to PVD
  - sensory: poor vision, decreased peripheral sensation/proprioception
- interpersonal/social factors

- environmental changes
  - iatrogenic (healthcare facilities)
  - deconditioning secondary to prolonged bed rest
  - inadequate mobility aids
  - poorly controlled chronic and acute pain

Complications
- cardiovascular: orthostatic hypotension, venous thrombosis, embolism
- respiratory: decreased ventilation, atelectasis, pneumonia
- gastrointestinal: anorexia, constipation, incontinence, dehydration, malnutrition
- genitourinary: infection, urinary retention, bladder calculi, incontinence
- MSK: atrophy, contractures, bone loss
- skin: pressure injuries
- psychological: sensory deprivation, delirium, depression

Incontinence

Fecal Incontinence

Definition
- involuntary or inappropriate passing of feces that impacts social functioning or hygiene
- severity can range from unintentional flatus to the complete evacuation of bowel contents
- there are three subtypes:
  1. passive incontinence: involuntary discharge of stool or gas without awareness
  2. urge incontinence: discharge of fecal matter in spite of active attempts to retain bowel contents
  3. fecal seepage: leakage of stool following otherwise normal evacuation

Epidemiology
- the incidence of fecal incontinence differs by setting: community (17-36%), hospital (16%), and nursing home (33-65%)
- risk factors: constipation, age >80 yr, female sex, UI, impaired mobility, dementia, neurologic disease

Etiology
- physiological changes with age >80 yr (e.g. decreased external sphincter strength, decreased resting tone of internal sphincter, weakened anal squeeze, increased rectal compliance, and impaired anal sensation)
- trauma (e.g. vaginal delivery, pudendal nerve damage, cauda equina)
- iatrogenic
  - surgical (e.g. anorectal surgery, lateral internal sphincterotomy, hemorrhoidectomy, colorectal resection)
  - radiation (e.g. pelvic radiation)
- neurogenic (e.g. neuropathy, stroke, MS, diabetic neuropathy)
- anorectal/colorectal diseases (e.g. rectal prolapse, hemorrhoids, IBD, rectocele, cancer)
- medication (e.g. laxative, anticholinergics, antidepressants, caffeine, muscle relaxants)
- cognitive (e.g. dementia, willful soiling with psychosis)
- constipation/fecal impaction

Investigations (if cause not apparent from history and physical)
- differentiate true incontinence from frequency and urgency
- stool studies
- endorectal ultrasound
- colonoscopy, sigmoidoscopy, anoscopy
- anorectal manometry/functional testing

Management
- physiological changes with age: medication management (antimotility agents (e.g. loperamide), diet/bulking agents for loose stool), increase fluid intake, biofeedback, retraining of pelvic floor muscles, surgery
- trauma: direct surgical repair or augmentation of the sphincters
- iatrogenic: surgical repair, artificial sphincters
- neurogenic: medication management, abdominal massage, digital stimulation for dysfunction, biofeedback and behavioural training, prevent autonomic dysreflexia in spinal injury
- anorectal/colorectal diseases: treat underlying cause (optimize IBD medications), surgical (e.g. mass removal, prolapse repair, hemorrhoid removal, colostomy)
- medication-related causes: stop laxatives, lower dose, or discontinue any other offending agents
- cognitive: regular defecation program in patients with dementia, psychiatric consult (optimize medications and cognitive function)
- constipation/fecal impaction: disimpaction, prevent impaction, enema, or rectal irrigation
- safety assessment: assess bathroom distance, fall prevention strategies, need for a bedside commode, liaise with occupational therapy if necessary

Urinary Incontinence

• see Urology, U6

Definition

- complaint of any involuntary loss of urine
- there are 4 subtypes:
  1. stress incontinence: leakage associated with physical strain
  2. urge incontinence: leakage associated with strong urge to urinate
  3. overflow incontinence: leakage associated with poor bladder emptying
  4. functional incontinence: leakage due to illness or disability not related to the urinary tract

Transient Causes of Incontinence

DIAPERS
Delirium
Infection
Atrophic urethritis/vaginitis
Pharmaceuticals
Excessive urine output
Restricted mobility
Stool impaction

Epidemiology

- 15-30% prevalence dwelling in community and at least 50% of institutionalized older adults
- morbidity: cellulitis, pressure injuries, urinary tract infections, falls with fractures, sleep deprivation, social withdrawal, depression, sexual dysfunction
- not associated with increased mortality
- risk factors: impaired mobility, falls, medications, depression, TIA/stroke, dementia, CHF, obesity

Etiology

- physiologic changes with age: (e.g. decreased bladder capacity)
- genitourinary diseases (e.g. cystitis, urethritis, BPH)
- neurogenic (e.g. cauda equina syndrome, stroke, MS)
- iatrogenic: (e.g. prostate surgery)
- trauma: (e.g. pelvic trauma, traumatic spinal cord injury)
- drugs (e.g. alcohol, loop diuretics, sedative hypnotics, GABAergic agents)
- cognitive (e.g. dementia, depression)
- functional impairment (e.g. arthritis, poor vision)

Investigations

- laboratory tests: urinalysis and urine culture, serum creatinine, BUN
- imaging: post-void residual, renal ultrasound
- other: voiding diary, pad test

Management

- lifestyle modification: avoid excessive fluid intake and alcohol
- pharmacologic: β-adrenergic agonists to reduce involuntary bladder contractions
- physiologic changes with age: pelvic muscle exercises, bladder training, biofeedback
- genitourinary diseases: treat underlying cause (empiric antimicrobial treatment for cystitis, α blockers/5-α reductase inhibitors for BPH)
- functional impairment: incontinence pads, environmental modification, personal assistance
- cognitive: referral to incontinence program if needed
- safety assessment: assess bathroom distance, fall prevention strategies, need for a bedside commode, liaise with occupational therapy if necessary

Malnutrition

Definition

- no uniformly accepted definition of malnutrition in older adults. One definition provided by the 2018 Global Leadership Initiative on Malnutrition requires a combination of one phenotypic and one etiologic finding:
  - phenotype
    - weight loss: >5% within past 6 mo or 10% beyond 6 mo
    - low BMI
    - reduced muscle mass measured by DXA, BIA, CT or MRI
  - etiology
    - reduced food intake
    - inflammation: from acute disease/injury or chronic disease-related
- other definitions include: hypocholesterolemia (<4.1 mmol/L), hypoalbuminemia (community: ≤38 g/L; hospital: ≤35 g/L), insufficient energy intake, fluid accumulation (e.g. edema), loss of subcutaneous fat, decreased hand-grip function

Etiology of Malnutrition in Older Adults

MEALS ON WHEELS
Medications
Emotional problems
Anorexia
Late-life paranoia
Swallowing disorders
Oral problems
Nosocomial infections
Wandering/dementia related activity
Hyperthyroid/hypercalcemia/hypoadrenalism
Enteric disorders
Eating problems
Low-salt/low-fat diet
Stones

Etiology

- nutritional
  - decreased assimilation: impaired transit, maldigestion, malabsorption
  - decreased intake: financial, psychiatric (depression), cognitive deficits, anorexia associated with chronic disease, functional deficits (e.g. difficulty shopping, preparing meals, or feeding oneself due to functional impairment), substance use
- stress: acute or chronic illness/infection, chronic inflammation, abdominal pain
- mechanical: dental problems, dysphagia

- age-related changes: decreased thirst, decreased smell and taste, delayed gastric emptying causing early satiety, decreased ghrelin production
- mixed: increased energy demands (e.g. hyperthyroidism), abnormal metabolism, protein-losing enteropathy

Clinical Features
- history
  - weight loss in 6 mo prior to examination
  - recent or chronic illness
  - constitutional symptoms (e.g. recent weight loss)
  - dietary intake in relation to usual pattern
  - depression, GI symptoms (e.g. anorexia, nausea, vomiting, diarrhea)
  - functional disability: impaired ADLs and IADLs, cognitive decline ("forgetting meals")
  - social factors: economic barriers, dental problems, and living situation (e.g. living alone)
  - substance use (e.g. alcohol, smoking, IV or recreational drug use)
- physical exam
  - BMI <23.5 in males and <22.0 in females should raise concern
  - muscle wasting, temporal wasting, presence of triceps skin fold
  - loss of subcutaneous fat
  - ankle or sacral edema, ascites
  - assess cognition

Investigations
- CBC, electrolytes, Ca^{2+}/albumin, Mg^{2+}, PO_4^{3-}, creatinine, LFTs (INR, bilirubin), vitamin B_{12}, folate, TSH, lipid profile
- if indicated by assessment, can consider urinalysis, ESR, CXR

Treatment
- direct treatment of underlying causes, encourage meals with family, friends or caregivers ("social eating")
- dietary modification: high calorie foods, oral nutritional supplementation with high protein supplementation preferred: patient specific meal replacement products (e.g. Ensure™, Glucerna™, Nepro™), vitamins/minerals (e.g. vitamin B12, calcium, vitamin D, thiamine)
- referral: speech language pathologist, nutritionist

Presbycusis

- see Otolaryngology, OT19

Presbyopia

- see Ophthalmology, OP8

Pressure Injuries

- see Plastic Surgery, *Pressure Ulcers*, PL17

Definition
- previously termed pressure ulcers/injuries, also termed decubitus ulcers
- any lesion caused by unrelieved pressure resulting in damage of underlying tissue; usually develops over bony prominences

Risk Factors
- extrinsic: friction, pressure, shear force, moisture
- intrinsic: immobility, malnutrition, comorbidities (e.g. DM, PVD, vasculitis, immunodeficiency, CHF), sensory loss
- geriatric: age-related skin changes, bedbound, cognitive impairment, chronic illness

Risk Assessment and Prevention of Pressure Ulcers
Ann Intern Med 2015;162:359-369
The American College of Physicians (ACP) strongly recommends advanced static mattresses or advanced static overlays for patients who are at an increased risk of developing pressure injuries. The ACP also recommends against using alternating air mattresses or alternating air overlays.

Table 5. NPIAP Staging System for Pressure Injuries

Stage 1	Localized area of nonblanchable erythema of intact skin (appearance may vary in darkly pigmented skin) Changes in sensation, temperature, or firmness may precede visual changes Colour changes do not include purple or maroon discolouration (may indicate deep tissue penetration injury)
Stage 2	Partial thickness loss of skin with exposed dermis Wound bed is viable, pink or red, moist, and may present as a serum-filled blister Adipose and deeper tissue not visible
Stage 3	Full thickness loss of skin; adipose tissue visible Slough and/or eschar may be visible Granulation tissue and epibole (rolled wound edges) often present
Stage 4	Full thickness skin and tissue loss Exposed or directly palpable fascia, muscle, tendon, ligament, cartilage, or bone Slough or eschar can be present on some parts of the wound bed Epibole, undermining, and/or tunneling often present
Unstageable Pressure Injury	Full-thickness skin and tissue loss; extent of tissue damage cannot be determined due to obstruction by slough or eschar
Deep Tissue Pressure Injury	Intact or nonintact skin with localized nonblanchable maroon or purple discolouration, or epidermal separation revealing dark wound bed or blood-filled blister Pain and temperature changes may precede skin colour changes Injury results from intense and/or prolonged pressure and shear forces at the bone-muscle interface

Source: Edsberg LE, Black JM, Goldberg M, et al. Revised National Pressure Ulcer Advisory Panel Pressure Injury Staging System: Revised Pressure Injury Staging System. J Wound Ostomy Continence Nurs 2016;43(6):585-597

Complications

- noninfectious: amyloidosis, heterotopic bone formation, perineal urethral fistula, pseudoaneurysm, Marjolin ulcer, systemic complications of topical treatment, complications of oral/IV treatments
- infectious: bacteremia/sepsis, cellulitis, osteomyelitis, septic arthritis, sinus tracts, abscess, endocarditis, meningitis

Prevention

- barrier cream to sacral area
- pressure reduction
  - frequent repositioning (q2 h in bed, q1 h in chair)
- support services (alternating-pressure mattresses/overlays, low-air-loss beds)
- optimizing nutritional status, encouraging mobility, and managing incontinence
- use validated pressure injury risk assessment (head-to-toe) tools on admission for those identified to be at risk for skin breakdown

Treatment

- optimize nutritional status
- minimize pressure on wound
- analgesia
- all ulcers with necrosis warrant debridement (mechanical, enzymatic, and autolytic are non-urgent forms of debridement, whereas sharp debridement is performed urgently due to risk of sepsis or cellulitis)
- dressing application (exudate absorbing, barrier products to reduce friction)
- maintain moist wound environment to enable re-epithelialization
- treatment of wound infections (topical gentamicin, silver sulfadiazine, mupirocin)
- swab wounds not demonstrating clinical improvement for C&S; biopsy chronic wounds to rule out malignancy
- referral to Wound Care or Plastic Surgery
- consider other treatment options:
  - negative pressure wound therapy/vacuum-assisted closure
  - biological agents: application of fibroblast growth factor or platelet-derived growth factor to wound
  - non-contact normothermic wound therapy
  - electrotherapy

Driving Competency

Reporting Requirements

- physician-reporting to the Ministry of Transportation is mandatory in all provinces and territories except in Quebec, Nova Scotia, and Alberta, where it is discretionary
- British Columbia, Ontario: must refer for re-test at ≥80 yr
- in the U.S., varies by state

Conditions That May Impair Driving

Table 6. Conditions That Impair Driving

Alcohol	Patients with history of impaired driving and those with a high probability of future impaired driving should not drive until further assessed
	Alcohol dependence or alcohol use disorder: if suspected, should be advised not to drive
	Alcohol withdrawal seizure: must (1) receive favourable report from addictions counsellor post-treatment and (2) be in remission and/or remained abstinent for 12 mo
Blood Pressure Abnormalities	HTN: sustained BP >170/110 should be evaluated carefully
	Hypotension: sustained BP <90/60; if syncopal, discontinue driving until syncope is treated and preventable
Cardiovascular Disease	Suspected asymptomatic CAD or stable angina: no restrictions
	STEMI, NSTEMI with significant LV damage, coronary artery bypass surgery: no driving for 1 mo following hospital discharge
	NSTEMI with minor LV damage, unstable angina: no driving for 48 h if PCI or 7 d if no PCI performed
Cerebrovascular Conditions	TIA: should not be allowed to drive until a medical assessment is completed
	Stroke: should not drive for at least 1 mo; may resume driving if functionally able; no clinically significant motor, cognitive, perceptual, or vision deficits; no obvious risk of sudden recurrence; underlying cause appropriately treated; no post-stroke seizure
COPD	Mild/moderate impairment: no restrictions
	Moderate or severe impairment requiring supplemental oxygen: road test with supplemental oxygen
Cognitive Impairment/Dementia	Moderate to severe dementia is a contraindication to driving, defined as the "inability to independently perform 2 or more IADLs or any basic ADL"
	Patients with mild dementia should be assessed; if indicated, refer to specialized driving testing centre; if deemed fit to drive, re-evaluate patient every 6-12 mo
	Poor performance on MMSE, clock drawing, or Trails B suggests a need to investigate driving ability further
	MMSE score alone (whether normal or low) is insufficient to determine fitness to drive
Diabetes	Diet controlled or oral hypoglycemic agents: no restrictions in absence of diabetes complications that may impair ability to drive (e.g. retinopathy, nephropathy, neuropathy, cardiovascular, or cerebrovascular disease)
	Insulin use: may drive if no complications (as above) and no severe hypoglycemic episode in the last 6 mo
Drugs	Be aware of: analgesics, anticholinergics, anticonvulsants, antidepressants, antipsychotics, opiates, sedatives, stimulants
	Degree of impairment varies: patients should be warned of the medication/withdrawal effect on driving
Hearing Loss	Effect of impaired hearing on ability to drive safely is controversial
	Acute labyrinthitis, positional vertigo with horizontal head movement, recurrent vertigo: advise not to drive until condition resolves
Musculoskeletal Disorders	Physician's role is to report etiology, prognosis, and extent of disability (pain, range of motion, coordination, muscle strength)
Postoperative	Outpatient, conscious sedation: no driving for 24 h
	Outpatient, general anesthesia: no driving for ≥24 h
Seizures	First, single, unprovoked: no driving for 3 mo until complete neurologic assessment, EEG, CT head
	Epilepsy: can drive if seizure-free for 6 mo, on medication that does not impair ability to drive, and physician has insight into patient compliance (Ontario guideline)
Sleep Disorders	If patient is believed to be at risk due to a symptomatic sleep disorder but refuses investigation with a sleep study or refuses appropriate treatment, the patient should not drive
Visual Impairment	Visual acuity: contraindicated to drive if <20/50 with both eyes examined simultaneously
	Visual field: contraindicated to drive if <120° along horizontal meridian and 15° continuous above and below fixation with both eyes examined simultaneously

N.B. guidelines included refer specifically to private driving; please see CMA guidelines for commercial driving

Key Factors to Consider in Older Drivers
SAFEDRIVE
Safety record
Attention (e.g. concentration lapses, episodes of disorientation)
Family observations
Ethanol use
Drugs
Reaction time
Intellectual impairment
Vision/Visuospatial function
Executive functions (e.g. planning, decision-making, self-monitoring behaviours)
Geriatrics 1996;51:36-45

Cognitive Tests and Determining Fitness to Drive in Dementia: A Systematic Review
J Am Geriatr Soc 2016;64(9):1904-1917
Purpose: To examine the relationship between cognitive tests and driving to determine whether a cognitive assessment can be implemented as a tool to examine driver safety.
Methods: Systematic review of 28 studies investigating the relationship between cognitive functioning and driving in individuals with dementia.
Results: Composite batteries comprising multiple individual tests from different cognitive domains consistently predicted driving performance for individuals with dementia. Scores on individual tests or tests of a single cognitive domain did not predict driver safety.
Conclusions: While studies consistently found composite batteries predicted driving performance, these tests were not clinically usable as they lacked the ability to discriminate between safe and unsafe drivers. Need development of a reliable, valid composite battery that can correctly determine driver safety in patients with dementia.

Hazards of Hospitalization

Table 7. Recommendations for Sequelae of Hospitalization in Older Patients

Sequelae	Recommendations
Malnutrition	No dietary restrictions (except diabetes and salt restriction if applicable), assistance, dentures if necessary, sitting in a chair to eat
Urinary Incontinence	Medication review, remove environmental barriers, discontinue use of catheter
Depression	Routine screening
Adverse Drug Event	Medication review
Confusion/Delirium	Orientation, visual and hearing aids, volume repletion, noise reduction, early mobilization, medication review, remove restraints
Pressure Injuries	Reactive air surface support services, daily inspection, repositioning every 2 h, nutrition
Infection	Early mobilization, remove unnecessary IV lines, catheters, NG tubes
Falls	Appropriate footwear, assistive devices, early mobilization, remove restraints, medication review
Hypotension/Dehydration	Early recognition and repletion (ideally oral rehydration, if possible), access to water
Diminished Aerobic Capacity/Loss of Muscle Strength/ Contractures	Early mobilization
Decreased Respiratory Function	Incentive spirometry, physiotherapy
Functional Decline	Structured exercise, progressive resistance training, walking programs

Bell SP, Vasilevskis EE, Saraf AA, et al. Geriatric Syndromes in Hospitalized Older Adults Discharged to Skilled Nursing Facilities. J Am Geriatr Soc 2016;64(4):715–722

Healthcare Institutions

Table 8. Classification of Healthcare Services and Institutions

Institution/Service	Description
Home and Community Support Services	At-home support services offered to patients living at home independently or under the care of family members. These include professional healthcare services, personal care and support (ADL assistance), homemaking (IADL assistance), community support services (e.g. transportation, meal delivery, day programs, caregiver relief, security checks)
Rehabilitation	Healthcare services offered in an institution to optimize patients' function, independence, and quality of life
Residential	Divided into short (<60-90 d/yr) and long (indefinite) stay
a) Older adults Affordable Housing	Seniors who live independently and manage their own care, but prefer to live near other older adults; usually has accessibility features; rent is adjusted based on income
b) Retirement Home	Residents are fairly independent and require minimal support with ADLs and IADLs; often privately owned
c) Supportive Housing	Residents require minimal to moderate assistance with daily activities while living independently; often rental units in an apartment; may offer physiotherapy and rehabilitation services
d) Long-term Care/Skilled Nursing Facility	Around the clock nursing care and on-call physician coverage; often offers occupational therapy, physiotherapy, respiratory therapy, and rehabilitation services; may be used short-term for caregiver respite or for supportive patient care to regain strength and confidence after leaving the hospital
e) Hospice	Free-standing facility or designated floor in a hospital or nursing home for care of terminally ill patients and their families; focus is on quality of life and often requires prognosis ≤ 3 mo

- names of community healthcare institutions, types of facilities, and services offered vary between geographical locations
- factors to consider when referring to community services and institutions: level and type of support required, income/socioeconomic status, social supports and/or degree of social isolation, other social determinants of health creating potential barriers to care

Geriatric Pharmacology

Pharmacokinetics

Table 9. Age-Associated Pharmacokinetics

Parameter	Age Effect	Implications
Absorption (less significant)	Increased gastric pH, decreased splanchnic blood flow, GI absorptive surface and dermal vascularity, delayed gastric emptying. However, appropriate absorption of most oral drugs is seen in healthy older-aged patients except for drugs with extensive first pass metabolism; reduced absorption may be related to patient comorbidities	Comorbidities, drug-drug, and drug-food interactions are more likely to affect absorption
Distribution	Increased total body fat Decreased lean body mass and total body water Increased α1-glycoprotein Decreased albumin	Lipophilic drugs have a larger volume of distribution Decreased volume of distribution of hydrophilic drugs Increased binding of basic drugs Decreased binding of acidic drugs
Metabolism (aging effect less significant)	Decreased hepatic mass and hepatic blood flow; impaired phase I reactions (oxidative system)	Lower doses may be therapeutic
Elimination	Decreased renal blood flow, glomerular filtration rate, tubular secretion Overall reduction in renal function by 30-50%	Lower doses may be therapeutic

Pharmacodynamics

Drug Sensitivity
- changes in pharmacokinetics as well as intrinsic sensitivity lead to altered drug responses
- increased sensitivity to warfarin, sedatives, antipsychotics, anticholinergics, digoxin, and narcotics
- decreased sensitivity to β-blockers and β-adrenergic stimulants, though may have increased sensitivity

Decreased Homeostasis
- poorer compensatory mechanisms leading to more adverse reactions (e.g. bleeding with NSAIDs/anticoagulants, altered mental status with anticholinergic/sympathomimetic/anti-Parkinsonian drugs)

Polypharmacy

Definition
- prescription, administration, or use of more medications than are clinically indicated

Epidemiology
- in Canada, >60% of older adults reported using ≥5 medications
- hospitalized older adults are given an average of 10 medications during admission

Risk Factors for Polypharmacy
- patient-level risk factors: age, female sex, cognitive impairment, low health literacy, frailty, mental health conditions, multiple chronic conditions, lack of primary care physician, residing in LTC, multiple pharmacies
- systems-level risk factors: multiple prescribers, poor documentation systems, automated refill systems, lack of systematic medication review

Risk Factors for Non-Compliance
- greater number of medications (compliance with 1 medication is 80%, but drops to 25% with ≥6 medications)
- increased dosing frequency, complicated container design, financial constraints, and cognitive impairment

Adverse Drug Reactions (ADRs)
- any noxious or unintended response to a drug that occurs at doses used for prophylaxis or therapy
- risk factors in older adults
  - intrinsic: comorbidities (>5), age >85, low BMI, age-related changes in pharmacokinetics and pharmacodynamics, CrCl <50 mL/min
  - extrinsic: number of medications (>9 medications, >12 doses/d), multiple prescribers, unreliable drug history, prior ADR

New medications: Start Low, Go Slow! Avoid starting 2 drugs at the same time.

Adverse drug reactions in older adults may present as delirium, falls, fractures, urinary incontinence/retention, or fecal incontinence/impaction. Any new symptom in older adult could be medication related until proven otherwise.

- prescribing cascade: process whereby an ADR is misinterpreted as a new medical condition, and a subsequent drug is prescribed to treat the initial drug-induced event. Providers should ask themselves:
  - is the new drug being prescribed to address an adverse event from a previously prescribed drug therapy?
  - is the initial drug therapy really needed, especially if leading to a drug cascade?
  - do the benefits of the initial drug therapy outweigh the harms?

Preventing Polypharmacy

- consider drug: safer side effect profiles, convenient dosing schedules, convenient route, efficacy
- consider patient: other medications, clinical indications, medical comorbidities
- consider patient-drug interaction risk factors for ADRs
- review drug list regularly to eliminate medications with no clinical indication or with evidence of toxicity
- avoid treating an ADR with another medication

Inappropriate Prescribing in Older Adults

Epidemiology

- the estimated prevalence of potentially inappropriate prescribing ranges from 12-40%

Beers Criteria

- a list of medications to avoid in adults ≥65 yr due to safety concerns
- 2019 update lists drugs that are inappropriate in most older adults, those that should typically be avoided with certain conditions, drugs to use with caution, drug-drug interactions, and drug dose adjustment based on kidney function
- examples include long-acting benzodiazepines, strong anticholinergics, high-dose sedatives

STOPP/START Criteria

- another screening tool for potentially inappropriate prescribing in older adults
- STOPP: Screening Tool of Older Person's Prescriptions
  - systems-based list of medications contraindicated in adults ≥65 yr in the context of their diagnoses
- START: Screening Tool to Alert physicians to Right Treatment
  - systems-based list of medications indicated in adults ≥65 yr in the context of their diagnoses
- older adults are often under-treated (ACEI, ASA, β-blockers, thrombolytics, oral anticoagulants)

Principles for Prescribing in Older Adults

CARED
Caution/Compliance
Age (adjust dosage for age)
Review regimen regularly
Educate
Discontinue unnecessary medications
Geriatric Pearls. Philadelphia: FA Davis Company, 1999

Inappropriate prescribing in older persons: A systematic review of medications available in different criteria
Arch Gerontol Geriatr 2017;68:55-61
Purpose: Comprehensive review of all potentially inappropriate medications for older persons, included in prescribing criteria of the last decade.
Results: From 778 articles, 14 criteria were included in the final analysis, including a total of 729 medication classes among all analyzed criteria. Diazepam was included in all 14 criteria, followed by amitriptyline in 13 criteria and doxepin in 12 criteria. Benzodiazepines, antihistamines, and antipsychotics were the most common drugs reported as potentially inappropriate for older adults, among final criteria.
Conclusion: Benzodiazepines, NSAIDs, antihistamines, and antipsychotics were the most common drugs reported as potentially inappropriate for older persons.

Common Medications

Table 10. Common Medications

Drug Name	Brand Name	Dosing Schedule	Indications	Contraindications	Side Effects	Mechanism of Action
Cognitive Enhancers						
donepezil	Aricept®	5-10 mg PO once daily	Moderate to severe dementia of Alzheimer's type	Known hypersensitivity, caution in untreated obstructive airway disease, cardiac conduction abnormalities, active PUD or occult GI bleed, seizure disorder, syncope NYD	N/V, diarrhea, anorexia, insomnia, fatigue, muscle cramps, syncope, bradycardia (uncommon), heart block (uncommon)	Reversible inhibition of acetylcholinesterase
galantamine	Reminyl®	8-12 mg PO BID	Mild to moderate dementia of Alzheimer's type	Known hypersensitivity, caution in untreated obstructive airway disease, cardiac conduction abnormalities, active PUD or occult GI bleed, seizure disorder, syncope NYD	N/V, diarrhea, anorexia, weight loss, headache, dizziness, syncope, heart block (rare), seizure (rare), delirium (rare)	Reversible inhibition of acetylcholinesterase
rivastigmine	Exelon®	1.5 mg PO BID (starting) up to 6-12 mg PO BID	Mild to moderate dementia of Alzheimer's type	Known hypersensitivity, severe hepatic disease, caution in untreated obstructive airway disease, cardiac conduction abnormalities, active PUD or occult GI bleed, seizure disorder, syncope NYD	N/V, diarrhea, headache, dizziness, anorexia, insomnia, weight loss, delirium, heart block (rare)	Acetylcholinesterase inhibition (reversible but very slow)
memantine	Ebixa®/Namenda® (Can)/(U.S.)	5 mg PO once daily (starting) up to 10 mg PO BID	Mild to moderate dementia of Alzheimer's type	Known hypersensitivity, conditions that alkalinize urine, caution in renal failure, seizures	Dizziness, headache, hypertension, constipation, confusion, hallucinations	NMDA-receptor antagonist
Laxatives						
bran	All-Bran®	1 cup PO once daily	Constipation		Bloating, flatus	Bulk-forming laxative
psyllium	Metamucil® Prodiem® Plain®	3.4 g PO once daily to TID	Constipation, hypercholesterolemia	N/V, abdominal pain, obstruction if another medication is taken within 2 h	Bloating, flatus	Bulk-forming laxative
lactulose	Chronulac® Cephulac® Kristalose®(U.S.) Acilac®; Apo-Lactulose®; Laxilose®; PMS-Lactulose® (Can)	15-30 cc PO once daily/BID and 5-10 mL PO BID for 2-4 wk for bowel evacuation after barium	Constipation, hepatic encephalopathy, bowel evacuation following barium exam	Patients on low galactose diets, abdominal pain, N/V	Flatus, cramps, nausea, diarrhea	Osmotic laxative
PEG 3350 (polyethylene glycol)	Lax-A-Day®, RestoraLAX®, Pegalax® (Can) Gavilax®, Healthylax® (U.S.)	17 g PO once daily (~1 heaping tablespoon) dissolved in 1 cup (250 mL) of beverage	Constipation, bowel prep (different dosing schedule)	Known/suspected bowel obstruction, known hypersensitivity, renal impairment	Abdominal cramps, bloating of the stomach, diarrhea, flatulence, nausea	Osmotic laxative
senna	Senokot®/Ex-lax®	2-4 tablets PO once daily or 10-15 mL syrup once daily/BID. Dosing should be the smallest required to pass soft stool	Constipation	Known/suspected bowel obstruction or abnormal constriction, atonic bowel, IBD, abdominal pain NYD, rectal bleeding NYD, severe dehydration	Abdominal cramps, N/V, diarrhea, urine and/or fecal discolouration	Stimulant laxative
bisacodyl	Dulcolax®	5-15 mg PO (10 mg PR)	Constipation	Acute GI diseases (e.g. appendicitis, diarrhea), ileus, obstruction, abdominal pain, N/V, severe dehydration, and ulcerative proctitis and/or anal fissures if PR	Abdominal cramps, pain, diarrhea, dehydration, dizziness, N/V	Stimulant laxative
Parkinsonian Agents – see Neurology, Table 26, N57						

Note: Docusate has been shown to be ineffective for the prevention/treatment of constipation in older adults

Landmark Geriatric Medicine Trials

Trial Name	Reference	Clinical Trial Details
FRAILTY		
Gait Speed and Survival in Older Adults, Studenski et al. 2011	JAMA 2011;305:50-58	**Title:** Gait Speed and Survival in Older Adults **Purpose**: Evaluate the relationship between gait speed and survival. **Methods**: Pooled analysis of 9 cohort studies of adults >65 yr with baseline gait speed data, followed up for 6-21 yr. The main outcomes were survival and life expectancy. **Results**: The overall 5-yr survival was 84.8% and 10-yr survival was 59.7%. Gait speed was associated with survival in all studies (pooled hazard ratio per 0.1 m/s, 0.88; 95% CI 0.87 to 0.90; P<0.001). Survival increased across the range of gait speeds with significant increments at 0.1 m/s. **Conclusions**: Gait speed was associated with 10-yr survival in all studies, with considerable variability in predicted 10-yr survival across the range of gait speeds, at 75 yr.
Frailty in Older Adults: Evidence for a Phenotype, Fried et al. 2001	J Gerontol A Biol Sci Med Sci 2001;56(3): M146-56	**Title:** Frailty in Older Adults: Evidence for a Phenotype **Purpose**: Develop phenotype of frailty as a clinical syndrome. **Methods**: Baseline and annual follow-up for outcomes of incident disease, hospitalization, falls, disability, and mortality in an original cohort of 4735 participants and later-recruited cohort of 582 African American participants. All participant data from the prospective observational Cardiovascular Health Study. **Results**: Frailty may be defined as the presence of three or more of: unintentional weight loss (10 lbs in past yr), self-reported exhaustion, weakness (grip strength), slow walking speed, low physical activity. Frailty is associated with increased risk of comorbidity and disability. **Conclusions**: Frailty in community-dwelling older adults may be defined as above. While comorbidity is a risk factor for frailty and disability is an outcome of frailty, frailty itself does not equal comorbidity or disability. Assessment for frailty is vital in identifying patients at increased risk for comorbidity and disability.
REHAB-AF	NEJM 2021;385:203-216	**Title:** Physical Rehabilitation for Older Patients Hospitalized for Heart Failure **Purpose**: Investigate interventions to address physical frailty in older patients hospitalized for acute decompensated heart failure. **Methods**: Multicenter, randomized, controlled trial to evaluate transitional, tailored, progressive rehabilitation intervention, including four physical-function domains initiated during or soon after heart failure hospitalization and continued post-discharge for 36 sessions. Primary outcome was Short Physical Performance Battery score, and secondary outcome was 6 month rehospitalization rate. **Results**: Older adults hospitalized for acute decompensated heart failure produce improved clinical outcomes when treated with this rehabilitation intervention program.
DELIRIUM		
Delirium is a Strong Risk Factor for Dementia in the Oldest-Old: A Population-Based Cohort Study, Davis et al. 2012	Brain 2012;135(9):2809-16	**Title:** Delirium is a Strong Risk Factor for Dementia in the Oldest-Old: A Population-Based Cohort Study **Purpose**: Use a true population sample to determine if delirium is an incident risk factor for incident dementia and cognitive decline. **Methods**: 553 individuals aged >85 yr were used to assess associations between delirium and incident dementia, as well as decline in MMSE scores. The relationship between dementia common neuropathological markers was modelled and stratified. **Results**: Delirium increased the risk of incident dementia (OR 8.7; 95% CI 2.1 to 35), worsened dementia severity (OR 3.1; 95% CI 1.5 to 6.3) and deterioration in global function score (OR 2.8; 95% CI 1.4 to 5.5). Delirium was associated with a loss of 1.0 more MMSE points per yr (95% CI 0.11 to 1.89) than those with no history of delirium. **Conclusions**: Delirium is a strong risk factor for incident dementia and cognitive decline in elderly patients
A Multicomponent Intervention to Prevent Delirium in Hospitalized Older Patients, Inouye et al. 1999	NEJM 1999;340:669-676	**Title:** A Multicomponent Intervention to Prevent Delirium in Hospitalized Older Patients **Purpose**: Evaluate the effectiveness of a multicomponent strategy for delirium prevention among older inpatients. **Methods**: A total of 852 inpatients ≥70 yr were included in the study. In lieu of randomization, prospective individual matching was used to compare patients admitted to an intervention unit vs. one of two usual care units. In the intervention unit, the multicomponent approach sought to address cognitive impairment, sleep deprivation, immobility, visual impairment, hearing impairment, and dehydration. **Results**: Delirium developed in 9.9% of patients in the intervention unit, vs. 15% in the usual care unit (95% CI 0.39 to 0.92). Total number of days with delirium (105 d vs. 161 d, P=0.02) and total number of delirium episodes (62 vs. 90, P=0.03) were both lower in the intervention unit. **Conclusions**: A multicomponent intervention model aimed at addressing risk factors for delirium in hospitalized older adults is effective at reducing delirium incidence and delirium duration.
FALLS		
PROFET	Lancet 1999;353:93-97	**Title:** Prevention of Falls in the Elderly Trial (Profet): A Randomised Controlled Trial **Purpose**: Assess the benefit of a structured interdisciplinary assessment of people who have fallen. **Methods**: Patients >65 yr presenting to ED with a fall were randomized to the intervention group (detailed medical and OT-therapy assessment with referral if indicated) or to a control group (usual care only). **Results**: The risk of falling was significantly lower in the intervention group compared to the control group (OR 0.39; 95% CI 0.23 to 0.66) as was the risk of fall recurrence (OR 0.33; 95% CI 0.16 to 0.68). **Conclusions**: Demonstrates that an interdisciplinary approach to elderly adults with a previous history of falls can significantly decrease the risk of further falls and limit functional impairment.
NEUROCOGNITIVE DISORDERS		
Donepezil and Memantine for Moderate-to-Severe Alzheimer's Disease, Howard et al. 2012	NEJM 2012;366:893-903	**Title:** Donepezil and Memantine for Moderate-to-Severe Alzheimer's Disease **Purpose**: Assess the benefits of cholinesterase inhibitors for the long-term treatment of moderate-severe Alzheimer's disease. **Methods**: 295 community-dwelling patients with moderate-severe Alzheimer's disease treated with donepezil were randomized to either continue donepezil, discontinue donepezil and start memantine, or continue donepezil and start memantine. The primary outcomes were SMMSE scores and Bristol Activities of Daily Living (BADLS) scores. **Results**: Patients assigned to continue donepezil, compared to those who discontinued, had a 1.9 higher average SMMSE score (95% CI 1.3 to 2.5). The score on the BADLS was lower (less impairment) by 3.0 points (95% CI 1.8 to 4.3) (P<0.001 for both comparisons). Patients who received memantine, compared with placebo, had a 1.2 higher average SMMSE score (95% CI 0.6 to 1.8, P <0.001) and BADLS score that was 1.5 points lower (95% CI 0.3 to 2.8; P=0.02). **Conclusions**: Continued treatment with donepezil was associated with cognitive benefits over the course of 12 mo in patients with moderate or severe Alzheimer's disease.

HYPERTENSION IN THE ELDERLY		
Syst-Eur	Lancet 1997;350:757-64	**Title:** Randomised Double-blind Comparison of Placebo and Active Treatment for Older Patients with Isolated Systolic Hypertension. The Systolic Hypertension in Europe (Syst-eur) Trial Investigators **Purpose**: Investigate whether active treatment could reduce CV complications of isolated systolic HTN. **Methods**: Patients >60 yr were randomly assigned to nitrendipine 10-40 mg daily with the possible addition of enalapril 5-20 mg daily and hydrochlorothiazide 12.5-25 mg daily, or to matching placebos. Combined fatal and nonfatal stroke was the primary endpoint. **Results**: Active treatment reduced the total rate of stroke from 13.7 to 7.9 endpoints per 1000 patient-years (43% reduction; P=0.003). Nonfatal stroke reduced by 44% (P=0.007) and nonfatal cardiac endpoints decreased by 33% (P=0.03). All-cause mortality was not influenced. **Conclusions**: Among elderly patients with isolated systolic hypertension, antihypertensive drug treatment starting with nitrendipine reduces the rate of cardiovascular complications.
HYVET	NEJM 2008;358:1887-98	**Title:** Treatment of Hypertension in Patients 80 Years of Age or Older **Purpose**: Determine whether treatment of hypertension is beneficial in patients >80 yr. **Methods**: 3845 patients >80 yr and a sustained sBP >160 mmHg were randomized to receive indapamide SR 1.5 mg or matching placebo. The ACEI perindopril 2 or 4 mg was added if necessary, to achieve the target BP of 150/80 mmHg. The primary endpoint was fatal or nonfatal stroke. **Results**: The mean BP at 2 yr was 15.0/6.1 mmHg lower in the active-treatment group than in the placebo group. Active treatment was associated with a 30% reduction in the rate of death from stroke (95% CI 1 to 62; P=0.05), a 21% reduction in all-cause mortality (95% CI; 4 to 35; P=0.02). Fewer adverse events were reported in the active-treatment group. **Conclusions**: Antihypertensive treatment with indapamide (sustained release), with or without perindopril, in adults >80 yr is beneficial.
INAPPROPRIATE PRESCRIBING IN THE ELDERLY		
EMPOWER	JAMA Intern Med 2014;174:890-98	**Title:** Reduction of Inappropriate Benzodiazepine Prescriptions Among Older Adults Through Direct Patient Education: The Empower Cluster Randomized Trial **Purpose**: Compare the effect of direct-to-consumer education against usual care on benzodiazepine discontinuation in older adults. **Methods**: 303 long-term users of benzodiazepines aged 65-95 were randomized to the educational intervention (deprescribing patient empowerment intervention explaining risks of benzodiazepine use and a stepwise taper protocol) or the 'wait list' control. Primary outcomes were benzodiazepine discontinuation after 6 mo. **Results**: At 6 mo, 27% of patients in the intervention group had discontinued benzodiazepines, compared with 5% in the control group (risk difference 23%; 95% CI 14% to 32%). **Conclusions**: Direct-to-consumer education describing the risks of benzodiazepine use and a stepwise tapering protocol effectively elicits shared decision making and discontinuation of medications that increase the risk of harm in older adults.
STOPP and START	Int J Clin Pharmacol Ther 2008;46:72-83	**Title:** STOPP (Screening Tool of Older Person's Prescriptions) and START (Screening Tool to Alert doctors to Right Treatment). Consensus validation **Purpose**: Validate a new screening tool of older persons' prescriptions, incorporating criteria for potentially inaccurate prescriptions (called STOPP), and criteria for appropriate prescriptions (called START). **Methods**: A Delphi consensus technique was used to obtain validity from an 18-member expert panel. Inter-rater reliability was assessed by determining the kappa-statistic on 100 datasets. **Results**: STOPP consists of 65 clinically significant criteria for potentially inappropriate prescriptions; START consists of 22 evidence-based prescribing indicators. **Conclusions**: STOPP/START is a valid, reliable, and comprehensive screening tool that enables the prescribing physician to appraise an older patient's prescription drugs in the context of his/her concurrent diagnoses.

Basic Anatomy Review

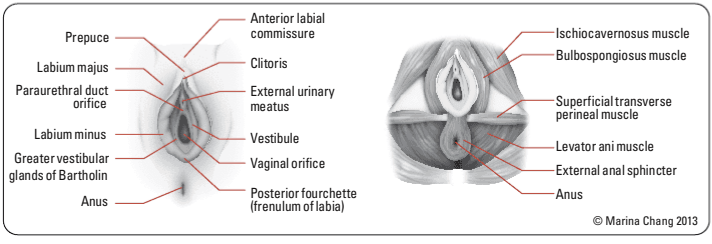

Figure 1. Vulva and perineum

A. External Genitalia

- blood supply: internal pudendal artery, superficial external pudendal artery (labia majora)
- sensory innervation: pudendal nerve
- lymphatic drainage: superficial inguinal lymph nodes, deep inguinal lymph nodes (clitoris)

B. Vagina

- muscular canal extending from cervix to vulva, anterior to rectum, and posterior to bladder
- lined by rugated, stratified squamous epithelium
- upper vagina separated by cervix into anterior, posterior, and lateral fornices
- blood supply: vaginal branch of internal pudendal artery with anastomoses from uterine, inferior vesical, and middle rectal arteries

C. Uterus

- thick walled, muscular organ between bladder and rectum, consisting of two major parts:
  - uterine corpus, made up of the isthmus, fundus, and body
    - blood supply: uterine artery (branch of the internal iliac artery, anterior division)
  - cervix
    - blood supply: cervical branch of uterine artery
- supported by the pelvic diaphragm, the pelvic organs, and four paired sets of ligaments
  - round ligaments: travel from anterior surface of uterus, through broad ligaments, and inguinal canals (canal of Nuck), then terminate in the labia major
    - function: anteversion/suspension
    - blood supply: Sampson's artery (branch of uterine artery running through round ligament)
  - uterosacral ligaments: arise from sacral fascia and insert into posterior inferior uterus
    - function: mechanical support for uterus, prevent prolapse, and contain autonomic nerve fibres

- cardinal ligaments: extend from lateral pelvic walls and insert into lateral cervix and vagina
  - function: mechanical support, prevent prolapse
- broad ligaments: pass from lateral pelvic wall to sides of uterus; contain fallopian tube, round ligament, ovarian ligament, nerves, vessels, and lymphatics. Within the broad ligament, the uterine artery anastomoses with the ovarian artery

- infundibulopelvic ligament (suspensory ligament of the ovary): continuous tissue that connects ovary to pelvic wall
  - contains the ovarian artery, ovarian vein, ovarian plexus, and lymphatic vessels
- position of the uterus
  - **anteverted** (majority), retroverted, neutral
  - **anteflexed** (more common), retroflexed

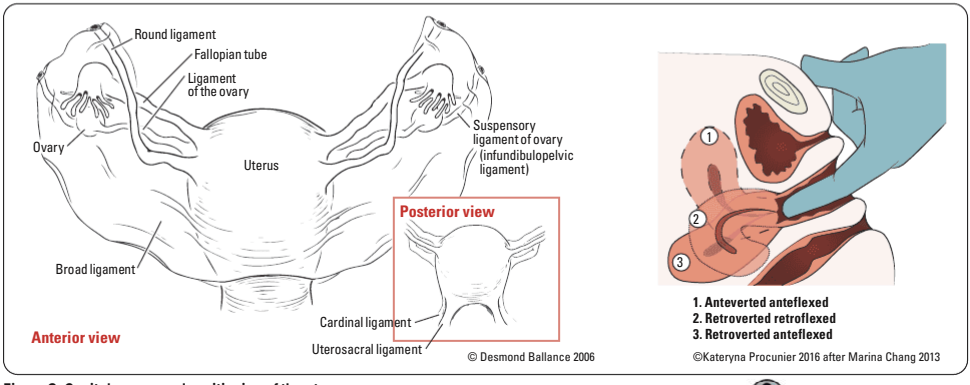

Figure 2. Genital organs and positioning of the uterus

D. Fallopian Tubes

- 8-14 cm muscular tubes extending laterally from the uterus to the ovary
- interstitial, isthmic, ampullary, and infundibular segments; terminates at fimbriae
- mesosalpinx: peritoneal fold that attaches fallopian tube to broad ligament
- blood supply: uterine and ovarian arteries

E. Ovaries

- consist of cortex with ova and medulla with blood supply
- supported by infundibulopelvic ligament (suspensory ligament of ovary)
- mesovarium: peritoneal fold that attaches ovary to broad ligament
- blood supply: ovarian arteries (branches off of aorta), left ovarian vein (drains into left renal vein), right ovarian vein (drains into inferior vena cava)

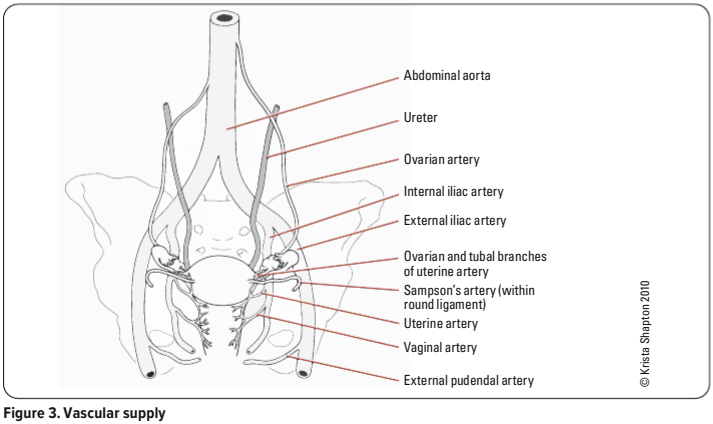

Figure 3. Vascular supply

Determination of Uterine Position by Clinical Exam

- If cervix faces anteriorly (under the urethra/pubic symphysis and less easily accessible), i.e. toward bladder more likely **RETROVERTED UTERUS**
- If cervix faces posteriorly (easily accessible), i.e. toward sacrum or rectum, more likely **ANTEVERTED UTERUS**
- If uterus is palpable with the abdominal hand on bimanual exam, more likely **ANTEVERTED UTERUS**
- If uterus is palpable behind the cervix in the posterior fornix, more likely **RETROVERTED UTERUS**

"Water Under the Bridge"
The ureters run inferior to the uterine arteries

Common Anatomy Questions in the OR

What is the origin of the left and right ovarian arteries?
Descending aorta
What are the drainage sites for the left and right ovarian veins?
Left to left renal vein, right to inferior vena cava
What is the most common place to locate the ureter?
In the pelvic brim, the ureter passes over the iliac vessels. The ureter can also be found in the medial leaf of the broad ligament where the ureter passes under the uterine artery
Which artery runs through the round ligament?
Sampson's artery

Menstruation

Menstrual Cycle

	FOLLICULAR/PROLIFERATIVE PHASE (Variable Duration)			LUTEAL/SECRETORY PHASE (Fixed Duration - 14 days)		
	Early	Mid	Late	OVULATION	Early-Mid	Late
Initiating Events	↓ E and ↓ P (from end of previous cycle)	↑ FSH acts on ovarian granulosa cells	Growing follicles continue to secrete E	Sudden switch from negative to positive feedback (E and P now ↑ FSH & LH)	Switch back to negative feedback	No fertilized oocyte
HPO Axis	↑ GnRH pulse frequency ↑ FSH ↑ LH pulse frequency	↑ E from follicles (ovary)		↑↑ LH pulse amplitude (LH surge)	↓ LH	
Hormones			↑ E from follicles, especially from dominant follicle	E peaks → LH surge → ovulation	↑ P from corpus luteum	↓ P secondary to degeneration of corpus luteum
Feedback on HPO Axis		Negative feedback E → ↓ FSH, ↓ LH		Positive feedback: E and P → ↑ FSH, ↑ LH	Negative feedback: P → ↓ FSH, ↓ LH	
Ovaries	↑ FSH → follicular growth in 3-30 follicles	↑ follicular growth (by reducing atresia) → ↑ E	Dominant follicle persists, remainder undergo atresia Granulosa cells luteinize → produce P	~36 h after LH surge, dominant follicle releases oocyte; corpus luteum (remnant of dominant follicle) produces P		Cessation of P from corpus luteum
Endometrium	Menses from P withdrawal (from end of previous cycle)				P stabilizes endometrium	Withdrawal of P → menses
Cervical Mucus		Cervical mucus: Clear, ↑ amount, Spinnbarkeit 8-10 cm, more stringy				Cervical mucus: Opaque, scant amount, Spinnbarkeit 1-2 cm

© Tess Peters 2009 and Sonya Amim 2003

CHARACTERISTICS
- Menarche 10-15 yr
- Average 12.2 yr
- Entire cycle 28 ± 7 d with bleeding for 1-6 d
- 25-80 mL blood loss per cycle

ESTROGEN
ESTROGEN is the main hormone in the follicular/proliferative phase and is stimulated by FSH. As the level increases it acts negatively on FSH. The majority of estrogen is secreted by the dominant follicle

Estrogen effects
- On the follicles in the ovaries: reduces atresia
- On the endometrium: proliferation of glandular and stromal tissue
- On all target tissues: decreases estrogen receptors

PROGESTERONE
PROGESTERONE is the main hormone in the luteal/secretory phase and is stimulated by LH. Increased progesterone acts negatively on LH and is secreted by the corpus luteum (remnant of dominant follicle)

Progesterone effects
- On the endometrium: cessation of mitoses (stops building endometrium up), "organization" of glands (initiates secretions from glands), inhibits macrophages, interleukin-8, and enzymes from degrading endometrium
- On all target tissues: decrease estrogen receptors (the "anti-estrogen" effect), decrease progesterone receptors

Figure 4. Events of the normal menstrual cycle
E = estrogen; FSH = follicle-stimulating hormone; GnRH = gonadotropin-releasing hormone; HPO = hypothalamic-pituitary-ovarian; LH = luteinizing hormone; P = progesterone

Stages of Puberty

- see Pediatrics, P7
- adrenarche: increased secretion of adrenal androgens; usually precedes gonadarche by 2 yr
- gonadarche: increased secretion of gonadal sex steroids; ~age 8 yr
- thelarche: breast development
- pubarche: pubic and axillary hair development
- menarche: onset of menses, usually following peak height velocity and/or 2 yr following breast budding

Stages of Puberty

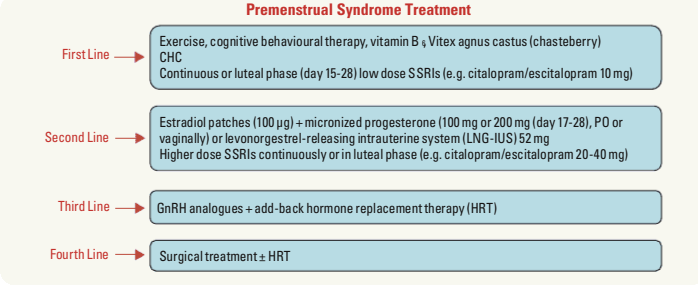
"Boobs, Pubes, Grow, Flow"
Thelarche, Pubarche, Growth spurt, Menarche

Premenstrual Syndrome

Definition
- physiological and emotional disturbances that occur 1-2 wk prior to menses and last until a few days after onset of menses; common symptoms include depression, irritability, tearfulness, and mood swings
- synonyms: "ovarian cycle syndrome," "menstrual molimina" (moodiness)

Etiology
- multifactorial: not completely understood; genetics likely play a role
- CNS-mediated neurotransmitter (serotonin, dopamine, GABA) interactions with sex steroids (progesterone, estrogen, and testosterone)
- serotonergic dysregulation – currently most plausible theory

Diagnostic Criteria for Premenstrual Syndrome
- at least one affective and one somatic symptom during the 5 d before menses in each of the three prior menstrual cycles
  - affective: depression, angry outbursts, irritability, anxiety, confusion, social withdrawal
  - somatic: breast tenderness or swelling, abdominal bloating, headache, swelling of extremities, joint or muscle pain, weight gain, fatigue
- symptoms relieved within 4 d of onset of menses and do not recur until at least day 13 of cycle
- symptoms present in the absence of any pharmacologic therapy, hormone ingestion, drug, or alcohol use
- symptoms occur reproducibly during 2 cycles of prospective recording
- patient suffers from identifiable dysfunction in social or occupational performance
- consider a PRISM (Prospective Record of the Impact and Severity of Menstrual symptoms) calendar to monitor symptoms and confirm diagnosis particularly with 3rd line treatment



Premenstrual Syndrome Treatment
First Line
Exercise, cognitive behavioural therapy, vitamin B 6 Vitex agnus castus (chasteberry)
CHC
Continuous or luteal phase (day 15-28) low dose SSRIs (e.g. citalopram/escitalopram 10 mg)
Second Line
Estradiol patches (100 µg) + micronized progesterone (100 mg or 200 mg (day 17-28), PO or vaginally) or levonorgestrel-releasing intrauterine system (LNG-IUS) 52 mg
Higher dose SSRIs continuously or in luteal phase (e.g. citalopram/escitalopram 20-40 mg)
Third Line
GnRH analogues + add-back hormone replacement therapy (HRT)
Fourth Line
Surgical treatment ± HRT

Figure 5. Royal College of Obstetricians and Gynecologists (RCOG) guidelines for treatment of premenstrual syndrome
Adapted from source: Management of Premenstrual Syndrome. Brit J Obstet Gynec 2016;48:1-33

Tanner Stage

Thelarche
1. None
2. Breast bud
3. Further enlargement of areolae and breasts with no separation of contours
4. 2° mound of areolae and papilla
5. Areolae recessed to general contour of breast

Pubarche
1. None
2. Downy hair along labia only
3. Darker/coarse hair extends over pubis
4. Adult-type hair with no thigh involvement
5. Adult hair in distribution and type, extends over thighs. Not all patients achieve Tanner Stage 5. For image see Pediatrics, P38

Premenstrual Dysphoric Disorder

Definition
- PMDD is similar to PMS but causes more severe symptoms and impairment of functioning

Clinical Features
- irritability and depressed mood
- breast pain and abdominal bloating

Diagnostic Criteria for Premenstrual Dysphoric Disorder
- at least 5 of the following 11 symptoms during most menstrual cycles of the last year (with at least 1 of the first 4)
  - depressed mood or hopelessness
  - anxiety or tension
  - affective instability

  - anger or irritability
  - decreased interest in activities
  - difficulty concentrating
  - lethargy
  - change in appetite
  - hypersomnia or insomnia
  - feeling overwhelmed
  - physical symptoms: breast tenderness/swelling, headaches, joint/muscle pain, bloating, or weight gain
- symptoms cause significant distress and/or interfere with social or occupational functioning
- symptoms must be present during the week prior to menses and resolve within a few days after onset of menses
- may be superimposed on other psychiatric disorders, provided it is not merely an exacerbation of another disorder

Common Investigations and Procedures

Imaging

Ultrasound

- transabdominal or transvaginal U/S is the imaging modality of choice for pelvic structures
- transvaginal U/S provides better resolution of uterus and adnexal structures
  - detects early pregnancy if β-hCG ≥1500 (β-hCG must be ≥6500 for transabdominal U/S)
- may be used to identify pelvic pathology
  - identify ectopic pregnancy, intrauterine pregnancy
  - assess uterine, adnexal, cul-de-sac, and ovarian masses (e.g. solid or cystic)
  - determine endometrial thickness, locate/characterise fibroids
  - detection of deep infiltrating endometriosis
  - monitor follicles during assisted reproduction
  - assess endometrial lining in postmenopausal patients

Endometrial Biopsy

- performed in the office using an endometrial suction curette (pipelle) guided through the cervix to aspirate fragments of endometrium
- pre-treatment with misoprostol (Cytotec®) is optional (less effective in postmenopause)
- more invasive procedure (i.e. D&C) may be done in the office or operating room ± hysteroscopy (this may be required if endometrial biopsy is not possible in the office setting or if there is suspicion for an endometrial polyp/intrauterine pathology or other risk factors for endometrial hyperplasia/cancer)
- detection rate of >97% for endometrial biopsy
- indications
  - AUB/PMB
    - age >40
    - risk factors for or history of endometrial cancer
    - failure of medical treatment
    - significant intermenstrual bleeding
    - consider in patients with infrequent menses suggesting anovulatory cycles
    - obesity

Hysterectomy

Indications

- uterine fibroids
- endometriosis, adenomyosis
- uterine prolapse
- pelvic pain
- AUB
- cancer (endometrium, ovaries, fallopian tubes, cervix)

Complications

- general anesthetic
- bleeding
- infection
- injury to other organs (ureter, bladder, rectum)
- loss of ovarian function (if ovaries removed, iatrogenic menopause)
- venous thromboembolism

No. 377 – Recommendations for Hysterectomy for Benign Gynaecological Indications in the SOGC Clinical Practice Guidelines
J Obs Gyn Can 2019; 41(4): 543-557
Summary:
1. Hysterectomy should be approached by either vaginal, laparoscopic, or open routes.
2. Correction of preoperative anemia (Hb <120 g/L), preoperative antibiotic prophylaxis, and measures to decrease risk of venous thromboembolism are recommended.
3. In patients with endometriosis, full excision of local endometriosis should be performed concurrently.
4. Opportunistic salpingectomy can be considered at the time of hysterectomy, but the planned surgical approach should not be changed for this sole purpose.
5. Urinary tract injury is a known complication of hysterectomy and there should be a low threshold for further investigation in cases where injury is suspected – consider routine cystoscopy.
6. Patients should be counseled about the benefits and risks of removing the ovaries, the risk of ovarian cancer vs. the long-term health implications of earlier menopause.

Approaches (www.tvasurg.com)

1. open (abdominal approach): uterus removed via transverse (Pfannenstiel, Maylard) or midline laparotomy
2. minimally invasive approaches
   - vaginal hysterectomy: entire procedure performed through the vagina; no abdominal incisions
   - laparoscopic-assisted vaginal hysterectomy: vascular pedicles are divided by a combination of laparoscopic and vaginal approaches
   - total laparoscopic hysterectomy: all vascular pedicles including the colpotomy approached laparoscopically and removed through the vagina or a mini-laparotomy
   - robotic: a type of laparoscopic approach; may be advantageous in patients with a high BMI, but more costly

Table 1. Classification of Hysterectomy

Classification	Tissues Removed	Indications
Subtotal Hysterectomy	Uterus	Inaccessible cervix (e.g. adhesions) Patient choice/preference
Total Hysterectomy (TH) (extrafascial simple hysterectomy/type 1) ± Bilateral Salpingectomy	Uterus, cervix, uterine artery ligated at uterus ± fallopian tubes	Uterine fibroids Endometriosis Adenomyosis Heavy menstrual bleeding DUB Tubes often removed opportunistically if already doing hysterectomy
Total Hysterectomy (TH) (extrafascial simple hysterectomy/type 1) and Bilateral Salpingo-Oophorectomy (BSO)	Uterus, cervix, uterine artery ligated at uterus, fallopian tubes, ovaries	Endometrial cancer Malignant adnexal masses Consider for endometriosis Any indication for hysterectomy in a postmenopausal patient
Modified Radical Hysterectomy (type 2)	Uterus, cervix, proximal 1/3 parametria, uterine artery ligated medial to the ureter, midpoint of uterosacral ligaments, and upper 1-2 cm vagina	Cervical cancer (up to stage 1B1)
Radical Hysterectomy (type 3)	Uterus, cervix, entire parametria, uterine artery ligated at its origin from internal iliac artery, uterosacral ligament at most distal attachment (rectum), and upper 1/3-1/2 vagina	Cervical cancer

Disorders of Menstruation

Amenorrhea

Differential Diagnosis of Amenorrhea

Table 2. Differential Diagnosis of Primary Amenorrhea

With Secondary Sexual Development		Without Secondary Sexual Development	
Normal Breast and Pelvic Development	**Normal Breast, Abnormal Uterine Development**	**High FSH (Hypergonadotropic Hypogonadism)**	**Low FSH (Hypogonadotropic Hypogonadism)**
Hypothyroidism Hyperprolactinemia PCOS Hypothalamic dysfunction	Androgen insensitivity Anatomic abnormalities Müllerian agenesis, uterovaginal septum, imperforate hymen	Gonadal dysgenesis Abnormal sex chromosomes (Turner's XO) Normal sex chromosomes (46XX, 46XY)	Constitutional delay (rare in girls) Congenital abnormalities Isolated GnRH deficiency Pituitary failure (Kallmann syndrome, head injury, pituitary adenoma, etc.) Acquired endocrine disorders (type 1 DM) Pituitary tumours Systemic disorders (IBD, JRA, chronic infections, etc.) Functional hypothalamic amenorrhea Asherman's Syndrome/uterine defect

Primary Amenorrhea
No menses by age 13 in absence of 2° sexual characteristics, or no menses by age 15 with 2° sexual characteristics, or no menses 2 yr after thelarche

Secondary Amenorrhea
No menses for >6 mo or 3 cycles after documented menarche

Most Common Causes of Primary Amenorrhea
1. Gonadal dysgenesis (e.g. Turner's Syndrome)
2. Functional hypothalamic amenorrhea
3. Mullerian agenesis

Table 3. Differential Diagnosis of Secondary Amenorrhea

With Hyperandrogenism	Without Hyperandrogenism
PCOS Autonomous hyperandrogenism (androgen secretion independent of the HPO axis) Ovarian: tumour, hyperthecosis Adrenal androgen-secreting tumour Late onset or mild congenital adrenal hyperplasia (rare)	Pregnancy Hypergonadotropic hypogonadism (i.e. primary ovarian insufficiency: high FSH, low estradiol) Idiopathic Autoimmune: type 1 DM, autoimmune thyroid disease, Addison's disease, celiac disease Iatrogenic: cyclophosphamide drugs, radiation Hyperprolactinemia Endocrinopathies: most commonly hyper or hypothyroidism Hypogonadotropic hypogonadism (low FSH): Pituitary compression or destruction: pituitary adenoma, craniopharyngioma, lymphocytic hypophysitis, infiltration (sarcoidosis), head injury, Sheehan's syndrome Functional hypothalamic amenorrhea (often related to stress, excessive exercise and/or anorexia)

Functional hypothalamic amenorrhea is the most common cause of secondary amenorrhea

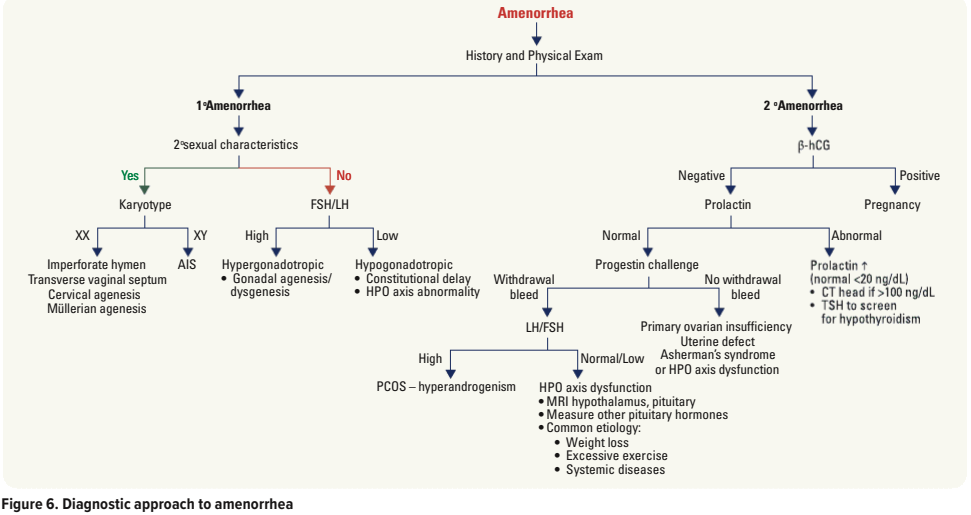


Figure 6. Diagnostic approach to amenorrhea

Investigations

- β-hCG, hormonal workup (TSH, prolactin, FSH, LH, androgens, estradiol)
- progesterone challenge to assess estrogen status
  - medroxyprogesterone acetate (Provera®) 10 mg PO once daily for 10-14 d
  - any uterine bleed within 2-7 d after completion of Provera® is considered to be a positive W/D test
    - W/D bleed suggests presence of adequate estrogen to thicken the endometrium; thus W/D of progesterone results in bleeding
    - if no bleeding occurs, this may be secondary to inadequate estrogen (hypoestrogenism), excessive androgens or progesterones (decidualization), pregnancy, obstructive causes (e.g. cervical stenosis), or structural causes (e.g. uterine adhesions)
- karyotype: indicated if primary ovarian insufficiency or absent puberty
- U/S to confirm normal anatomy, identify PCOS (in adult population only)

Prolactinoma Symptoms
Galactorrhea, visual changes, headache

Treatment

Table 4. Management of Amenorrhea

Etiology	Management
1° AMENORRHEA	
AIS	Gonadal resection after puberty
	Psychological counselling
	Creation of neo-vagina with dilation
Anatomical	
Imperforate hymen	Surgical management
Transverse vaginal septum	Surgical management
Cervical agenesis	Suppression and ultimately hysterectomy
Müllerian dysgenesis (MRKH syndrome)	Psychological counselling
	Creation of neo-vagina with dilation
	Diagnostic study to confirm normal urinary system and spine
2° AMENORRHEA	
HPO axis dysfunction	Identify modifiable underlying cause
	Combined OCP to decrease risk of osteoporosis, maintain normal vaginal and breast development (NOT proven to work) Correct the problem (weight)
Hyperprolactinemia	MRI/CT head to rule out lesion
	If no demonstrable lesions by MRI:
	Bromocriptine, cabergoline if fertility desired
	Combined OCPs if no fertility desired
	Demonstrable lesions by MRI: surgical management
Polycystic ovarian syndrome	See *Polycystic Ovarian Syndrome, GY25*
Premature ovarian failure	Screen for DM, hypothyroidism, hypoparathyroidism, hypocortisolism
	Hormonal therapy with estrogen and progestin to decrease risk of osteoporosis; can use OCP after induction of puberty
Uterine defect	Evaluation with hysterosalpingography or sonohysterography
Asherman's syndrome	Hysteroscopy: excision of synechiae

2° amenorrhea is pregnancy until proven otherwise

Abnormal Uterine Bleeding

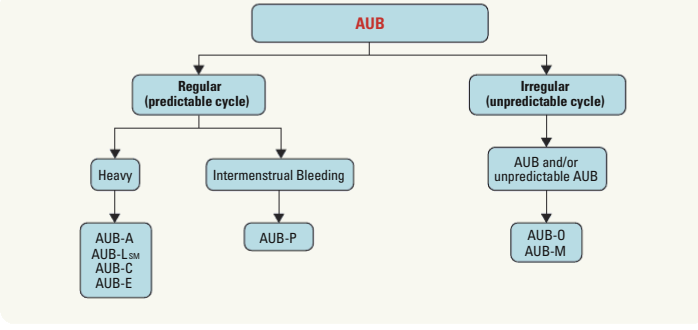

Figure 7. Diagnostic approach to abnormal uterine bleeding

The most common cause of postmenopausal bleeding is genitourinary syndrome of menopause (atrophy). However, endometrial cancer and hyperplasia must be ruled out with an endometrial biopsy before treatment for genitourinary syndrome of menopause (atrophy). 10% of post menstrual bleeding is endometrial cancer.

Approach

- menstrual bleeding should be evaluated by ascertaining: frequency/regularity of menses, duration, volume of flow, impact on quality of life, and timing (inter- or premenstrual, or breakthrough)
- is it regular?
  - regular: cycle to cycle variability of <20 d – "Can you predict your menses within 20 days?"
  - irregular: cycle to cycle variability of ≥20 d
- is it heavy?
  - questions: How frequently do pads/tampons need to be changed? How saturated? Any clots?
  - ≥80 cc of blood loss per cycle or
  - ≥8 d of bleeding per cycle or
  - bleeding that significantly affects quality of life

Abnormal Uterine Bleeding
Change in frequency, duration, or amount of menstrual flow that affects quality of life.

- is it structural?
  - PALM (see *Table 5*)
- is it non-structural?
  - COEIN (see *Table 5*)

Table 5. Abnormal Uterine Bleeding – Etiologies, Investigations, and Management

Etiology	Investigations	Management
	STRUCTURAL	
Polyps (AUB-P)	Transvaginal sonography Saline infusion sonohysterography	Polypectomy (triage based on symptoms, polyp size, histopathology, and patient age)
Adenomyosis (AUB-A)	Transvaginal sonography MRI	See *Adenomyosis, GY13*
Leiomyoma (AUB-L) Submucosal (AUB-Lsm) Other (AUB-Lo)	Transvaginal sonography Saline infusion sonohysterography Diagnostic hysteroscopy MRI	See *Fibroids, GY14*
Malignancy and Hyperplasia (AUB-M)	Transvaginal sonography Endometrial biopsy for all patients >40 yr with AUB, for patients <40 yr with persistent AUB, or endometrial cancer risk factors	Dependent on diagnosis
	NON-STRUCTURAL	
Coagulopathy (AUB-C)	CBC, coagulation profile (especially in adolescents), VWF, Ristocetin cofactor, factor VII	Dependent on diagnosis (hormonal modulation (e.g. OCP), Mirena IUS, endometrial ablation)
Ovulatory Dysfunction (AUB-O)	Bloodwork: β-hCG, ferritin, prolactin, FSH, LH, serum androgens (free testosterone, DHEA, androstenedione), progesterone, 17-hydroxy progesterone, TSH, free T4 Pelvic ultrasound	See *Infertility, GY23*
Endometrial (AUB-E)	Endometrial biopsy	Tranexamic acid Hormonal modulation (e.g. OCP) Mirena IUS Endometrial ablation
Iatrogenic (AUB-I)	Transvaginal sonography (rule out forgotten IUD) Review OCP/HRT use Review medications (especially neuroleptic use)	Remove offending agent
Not Yet Classified (AUB-N)	–	–

Treatment

- resuscitate patient if hemodynamically unstable
- treat underlying disorders
  - if anatomic lesions and systemic disease have been ruled out, consider AUB
- medical
  - mild AUB
    - NSAIDs
    - anti-fibrinolytic (e.g. Cyklokapron®) at time of menses
    - combined hormonal contraceptive
    - progestins (Provera®) on first 10-14 d of each month or every 3 mo if AUB-O
    - Mirena® IUD
    - correct anemia - iron
  - acute, severe AUB
    - replace fluid losses, consider admission
      a) anti-fibrinolytic (e.g. Cyklokapron®) 500-1000 mg PO BID-TID prn (up to 4 g/d)
      b) anti-fibrinolytic (e.g. Cyklokapron®) 10 mg/kg IV q8 h and/or estrogen (Premarin®) 25 mg IV q4 h x 24 h with Gravol® 50 mg IV/PO q4 h (rarely used)
      c) tapering OCP regimen, 35 µg pill (often Marvelon) TID x 7 d then taper to 1 pill/d for 3 wk with Gravol® 50 µg IV/PO q4 h
      d) tapering OCP to 1 tab TID x 2 d → BID x 2 d → once daily (more commonly used) after (a) or (b), maintain patient on monophasic OCP for next several months or consider alternative medical treatment
      (e) medical (can also consider):
        – high dose progestins
        – GnRH agonists (e.g. Lupron®) with add-back Norlutate if taken for >6 mo
        – progesterone IUD (Mirena)
        – danazol (Danocrine®)
- surgical
  - polypectomy
  - myomectomy
  - uterine artery embolization
    - if finished childbearing
  - endometrial ablation
    - if finished childbearing
  - repeat procedure may be required if symptoms recur, especially if <40 yr
    - hysterectomy: definitive treatment

Dysmenorrhea

Etiology

- primary/idiopathic
- secondary (acquired)
  - endometriosis
  - adenomyosis
  - uterine polyps
  - uterine anomalies (e.g. non-communicating uterine horn)
  - leiomyoma
  - intrauterine synechiae
  - ovarian cysts
  - cervical stenosis
  - imperforate hymen, transverse vaginal septum
  - PID
  - IUD (copper)
  - uterine polyps
  - foreign body

Primary Dysmenorrhea
Recurrent, crampy lower abdominal pain during menses in the absence of demonstrable disease

Secondary Dysmenorrhea
Pain during menses that can be attributed to an underlying disorder (i.e. endometriosis, adenomyosis, fibroids)

Table 6. Comparison of Primary and Secondary Dysmenorrhea

	Primary Dysmenorrhea	Secondary Dysmenorrhea
Features	Recurrent, crampy lower abdominal pain that occurs during menses in the absence of demonstrable disease	Similar features as primary dysmenorrhea but with an underlying disorder that can account for the symptoms, such as endometriosis, adenomyosis, or uterine fibroids
Signs and Symptoms	Colicky pain in abdomen, radiating to the lower back, labia, and inner thighs beginning hours before onset of bleeding and persisting for hours or days (48-72 h) Associated symptoms: N/V, altered bowel habits, headaches, fatigue (prostaglandin-associated)	Same symptoms as primary dysmenorrhea Associated symptoms: dyspareunia, abnormal bleeding, infertility
Diagnosis	Assess for associated dyspareunia, abnormal bleeding, infertility (signs of 2° dysmenorrhea) Rule out underlying pelvic pathology and confirm cyclic nature of pain Pelvic examination not required; indicated for patients not responding to therapy or with signs of organic pathology	Bimanual exam: uterine or adnexal tenderness, fixed uterine retroflexion, uterosacral nodularity, pelvic mass, or enlarged irregular uterus (findings are rare in patients <20 yr) U/S, laparoscopy, and hysteroscopy may be necessary to establish the diagnosis Vaginal and cervical cultures may be required
Treatment	Regular exercise, local heat NSAIDs: should be started before onset of pain CHCs with continuous or extended use: suppress ovulation/reduce menstrual flow	Treat underlying cause

Endometriosis

Definition

- the presence of endometrial tissue (glands and stroma) outside of the uterine cavity
- chronic condition, resolving only with menopause

Etiology

- not fully understood; proposed mechanisms include (combination likely involved):
  - retrograde menstruation (Sampson's theory)
  - immunologic: decreased NK cell activity limiting clearance of transplanted endometrial cells from pelvic cavity (may be due to decreased NK cell activity)
  - metaplasia of coelomic epithelium
  - extra-pelvic disease may be due to aberrant vascular or lymphatic dissemination of cells
    - e.g. ovarian endometriosis may be due to direct lymphatic flow from uterus to ovaries

Differential Diagnoses
- Chronic PID, recurrent acute salpingitis
- Hemorrhagic corpus luteum
- Benign/malignant ovarian neoplasm
- Ectopic pregnancy

Epidemiology

- incidence: 15-30% of premenopausal patients
- mean age at presentation: 25-30 yr
- regresses after menopause

4 "Dys" of Endometriosis
- Dysmenorrhea
- Dyspareunia (cul-de-sac, uterosacral ligament)
- Dyschezia (uterosacral ligament, cul-de-sac, rectosigmoid attachment)
- Dysuria (bladder involvement)

Risk Factors

- family history (7-10x increased risk if affected 1st degree relative)
- obstructive anomalies of the genital tract (earlier onset) – usually resolves with treatment of anomaly which relates to retrograde menses mechanism
- nulliparity
- age >25 yr
- early menarche (<11-13 y/o), shorter menstrual cycles (defined as ≤27 d)

Sites of Occurrence

- ovaries: 60% of patients have ovarian involvement
- broad ligament, vesicouterine fold
- peritoneal surface of the cul-de-sac, uterosacral ligaments
- rectosigmoid colon, appendix
- rarely may occur in sites outside abdomen/pelvis, including lungs and diaphragm

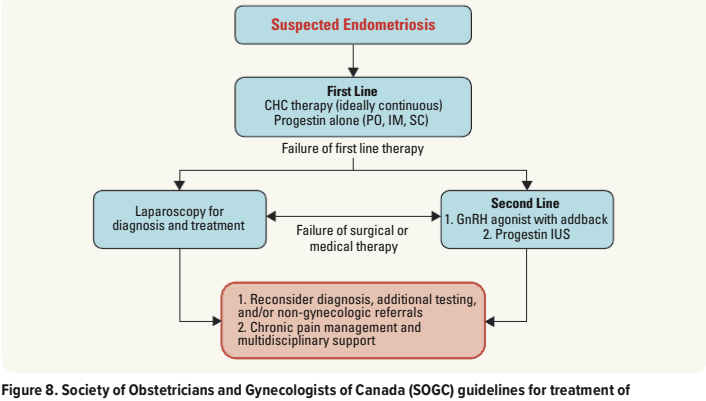
Clinical Features

- may be asymptomatic and can occur with one of 3 presentations

1. **pain** (80%)
   - menstrual symptoms
     - cyclic symptoms due to growth and bleeding of ectopic endometrium, usually precede menses (24-48 h) and continue throughout and after flow
     - secondary dysmenorrhea
     - sacral backache with menses
     - pain may eventually become chronic, worsening perimenstrually
     - deep dyspareunia
   - bowel and bladder symptoms
     - frequency, dysuria, hematuria
     - cyclic diarrhea/constipation, hematochezia, dyschezia (suggestive of deeply infiltrating disease)
2. **infertility** (25%)
   - 30-40% of patients with endometriosis will be infertile
   - 15-30% of those who are infertile will have endometriosis
3. **mass (endometrioma)** (20%)
   - endometrioma: an endometriotic cyst encompassing ovary
   - ovarian mass can present with any of above symptoms or be asymptomatic
   - physical examination:
     - tender nodularity of uterine ligaments and cul-de-sac felt on rectovaginal exam
     - fixed retroversion of uterus
     - firm, fixed adnexal mass

Investigations

- definitive diagnosis can be made based on:
  - direct visualization of lesions typical of endometriosis at laparoscopy (gold standard)
  - biopsy and histologic exam of specimens 2 or more of: endometrial epithelium, glands, stroma, hemosiderin-laden macrophages
- laparoscopy
  - mulberry spots: dark blue or brownish-black implants on the uterosacral ligaments, cul-de-sac, or anywhere in the pelvis
  - endometrioma: "chocolate" cysts on the ovaries
  - "powder-burn" lesions on the peritoneal surface
  - early white lesions and clear blebs
  - peritoneal "pockets"
- CA-125
  - may be elevated in patients with endometriosis but should NOT be used as a diagnostic test



Suspected Endometriosis
First Line
CHC therapy (ideally continuous)
Progestin alone (PO, IM, SC)
Failure of first line therapy
Laparoscopy for diagnosis and treatment
Failure of surgical or medical therapy
Second Line
1. GnRH agonist with addback
2. Progestin IUS
1. Reconsider diagnosis, additional testing, and/or non-gynecologic referrals
2. Chronic pain management and multidisciplinary support

Figure 8. Society of Obstetricians and Gynecologists of Canada (SOGC) guidelines for treatment of endometriosis

Long-Term Outcomes of Elagolix in Women with Endometriosis: Results from Two Extension Studies
Obstet Gynecol 2018;132:147-160
Purpose: An evaluation of the safety and efficacy of elagolix (a GnRH agonist) over 12 mo in women with endometriosis-associated pain.
Methods: A report of 2, double-blind, Phase III, placebo-controlled RCTs to evaluate two doses of elagolix over 12 mo of continuous treatment in patients with moderate to severe endometriosis-associated pain.
Results: In the first trial, 52.1% of women receiving 150 mg elagolix once daily had a clinical response with regards to dysmenorrhea and 67.8% had a response with regards to non-menstrual pelvic pain. In the higher dose group (200 mg q12 h), the response rate was 78.1% and 69.1%, respectively. These response rates were comparable in the second trial. Women who received elagolix had higher rates of hot flushes, higher serum lipids, and decreases in bone mineral density.
Conclusion: Both high and low doses of elagolix were effective in improving dysmenorrhea and non-menstrual pelvic pain in women with endometriosis-associated pain.

Endometriosis – Take Home Points

Suggestive history even with a negative exam should be considered adequate for a presumptive diagnosis

Pelvic pain that is not primary dysmenorrhea should be considered endometriosis until proven otherwise

Medical management is the mainstay of endometriosis

Consider surgery for patients who have not responded to medical management, fertility optimization, and/or large adnexal masses/adhesive disease causing obstruction. Medical management is often continued postoperatively

Treatment
- surgical confirmation of disease is NOT required prior to starting medical management. Asymptomatic endometriosis does not require treatment. Management depends on certainty of the diagnosis, severity of symptoms, extent of disease, desire for future fertility, and impact to GI/GU systems (e.g. intestinal obstruction)
- medical
  - medical suppression to prevent progression of disease, unless trying to conceive, which has not been proven in the literature
  - NSAIDs (e.g. naproxen sodium – Anaprox®). Avoid selective COX-2 inhibitors (celecoxib, rofecoxib, valdecoxib) in those who are attempting conception as some studies indicate these drugs can prevent or delay ovulation
  - 1st line
    - cyclic/continuous estrogen-progestin (OCP)
    - progestin (IM medroxyprogesterone (Depo-Provera®) or oral dienogest (Visanne®))
    - Mirena® IUS
  - 2nd line
    - GnRH agonist (e.g. leuprolide (Lupron®) or elagolix (Orlissa®)): suppresses pituitary gland and induces pseudomenopauses. Not a contraceptive
      - side effects: hot flashes, vaginal dryness, reduced libido
      - Lupron use >6 mo: include add-back progestin or estrogen to prevent decreased BMD, reduce vasomotor side effects
      - Orlissa® low dose (150 mg once daily) dose not require add-back progestin or estrogen. High dose (200 mg PO BID) dose require add-back
    - danazol (Danocrine®): weak androgen
      - side effects: weight gain, fluid retention, acne, hirsutism, voice change (not commonly used due to side effects)
- surgical
  - limited to failure of medical treatment, or desire for definitive treatment
  - conservative laparoscopy using laser, electrocautery ± laparotomy
    - ablation/resection of implants, lysis of adhesions, ovarian cystectomy of endometriomas
  - definitive: hysterectomy ± bilateral salpingo-oophorectomy
  - best time to become pregnant is immediately after conservative surgery
  - if patient is not planning to become pregnant postoperatively, suppress ovulation medically to prevent recurrence (not proven)
- above treatments are for the pain, not for the infertility associated with endometriosis, which usually involves surgery + assisted reproductive technologies. Also, management for endometriomas is surgical for symptomatic and expanding masses, but this can decrease ovarian reserve, so if it is asymptomatic and small (<5 cm), then no surgery is necessary

Adenomyosis

Definition
- synonym: "endometriosis interna" (uterine wall may be diffusely involved)

Adenomyosis
Extension of areas of endometrial glands and stroma into the myometrium

Epidemiology
- 15% of females >35 y/o; found in 20-40% of hysterectomy specimens
- mean age at presentation: 40-50 y/o (older age group than seen in endometriosis)
- adenomyosis is a common histologic finding in asymptomatic patients

Clinical Features
- often asymptomatic
- heavy menstrual bleeding, secondary dysmenorrhea, pelvic discomfort
- dyspareunia, dyschezia
- uterus symmetrically bulky, usually <14 cm
- Halban's sign: tender, softened uterus on premenstrual bimanual exam

Final diagnosis of adenomyosis is based on pathologic findings, but predictably identified on MRI

Investigations
- clinical diagnosis
- U/S or MRI can be helpful
- endometrial sampling to rule out other pathology

Treatment
- medical
  - iron supplements for anemia
  - analgesics, NSAIDs
  - Mirena® IUS
  - CHC, dinogest (Visanne®), medroxyprogesterone (Depo-Provera®) – limited evidence for efficacy
  - GnRH agonists (e.g. leuprolide (Lupron ®), elagolix (Orlissa®))
  - danazol 100-200 mg PO once daily (trial x 4 mo)
- surgical
  - definitive: hysterectomy – treatment of choice in patients who have completed childbearing

Fibroids

Leiomyomata/Fibroids
Benign smooth muscle tumour of the uterus (most common gynecological tumour)

Submucosal leiomyomata are most symptomatic (bleeding, infertility)

Large fibroids can cause distressing bulk symptoms

The effect of pregnancy on fibroid size is variable

Epidemiology
- diagnosed in approximately 40-50% of premenopausal patients >35 yr
- more common in Black patients, where they are also larger and occur at earlier age
- common indication for major surgery in females
- minimal malignant potential
- typically regress after menopause

Pathogenesis
- estrogen stimulates monoclonal smooth muscle proliferation
- progesterone stimulates production of proteins that inhibit apoptosis
- degenerative changes (occur when tumour outgrows blood supply)
  - fibroids can painfully degenerate, become calcified, develop sarcomatous component, or obtain parasitic blood supply

Classification
- International Federation of Gynecology and Obstetrics (FIGO) classifies fibroids by location and type
  - submucosal: grow within myometrium, can grow into endometrial cavity (FIGO type 0 - pedunculated, type 1 - <50% intramural, type 2 - ≥50% intramural)
  - intramural: most common, grow within the muscular wall of the uterus (FIGO type 3 - contacts endometrium and is 100% intramural, type 4 - intramural)
  - subserosal: grow from the serosa (FIGO type 5 - ≥ 50% intramural, type 6 - <50% intramural, type 7 - pedunculated)
  - cervical: located in cervix (FIGO type 8 - other)

Clinical Features
- majority asymptomatic, often discovered as incidental finding on pelvic exam or U/S (occur in 70-80% of women by age 50)
- symptoms classified into categories:
  - heavy or prolonged menstrual bleeding
    - AUB and menstrual cramps most common symptoms (26-29%) in symptomatic patients
  - pressure/bulk symptoms
    - pelvic pressure/heaviness
    - increased abdominal girth
    - urinary frequency, difficulty voiding
    - constipation, bloating (rare)
    - acute urinary retention (extremely rare, but surgical emergency!)
    - venous compression
  - reproductive dysfunction
    - infertility, recurrent pregnancy loss
    - pregnancy complications (fibroid degeneration, obstructed labour, malpresentation, difficult cesarean delivery)

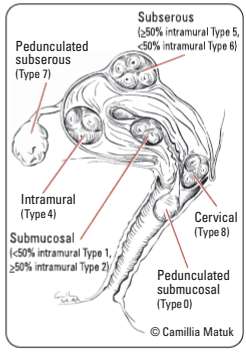


Figure 9. Possible anatomic locations of uterine leiomyomata

Investigations
- bimanual exam: uterus asymmetrically enlarged
- diagnosis typically made based on pelvic exam and pelvic U/S
- pelvic and/or transvaginal U/S: to confirm diagnosis and assess location of fibroids
- sonohysterogram: useful for differentiating polyps from submucosal fibroids, assessing size and degree of submucosal component, or assessing presence of submucosal fibroids which may impact fertility, or for planning hysteroscopic resection
- diagnostic office hysteroscopy: can be used instead of a sonohysterogram in patients with suspected submucosal fibroids or those desiring fertility to visualize the endometrial cavity, helps with planning of hysteroscopic submucosal fibroid resection, and rules out small polyps not visualized on U/S
- pregnancy test: performed for all patients of reproductive age via urine or serum pregnancy test to rule out pregnancy prior to start of the procedure
- occasionally MRI is used for preoperative planning (e.g. before consideration of laparoscopic myomectomy)
- endometrial biopsy: used in patients with AUB to rule out endometrial hyperplasia or cancer (especially if age >40 yr or risk factors (type 2 DM, obesity, chronic anovulation))
- CBC: anemia (only found if associated with AUB/heavy menstrual bleeding)

Treatment
- only if symptomatic (heavy menstrual bleeding, bulk symptoms), rapidly enlarging, or submucosal and affecting fertility
- whether patient desires fertility is key in guiding treatment options
- treat anemia if present
- conservative approach (watch and wait) if:
  - symptoms absent or minimal
  - fibroids <6-8 cm or stable in size
  - not submucosal (submucosal fibroids are more likely to be symptomatic)
  - currently pregnant (follow-up U/S if symptoms progress-may remove at delivery if CD
- medical approach to treat AUB-L
  - antiprostaglandins (ibuprofen, other NSAIDs)
  - tranexamic acid (Cyklokapron®)
  - CHC, hormonal IUS, or Depo-Provera®

Uterine Artery Embolization for Symptomatic Uterine Fibroids
Cochrane DB Syst Rev 2014;12:CD005073
Purpose: To compare outcomes of UAE to other. medical or surgical therapies for symptomatic uterine fibroids. Primary outcomes were patient satisfaction and live birth rate.
Results: Seven RCTs with 793 women were included. There was no evidence of a difference in the primary outcomes or risk of major complications between the interventions. UAE was associated with a higher risk of minor complications and the need for additional surgical intervention within 2 yr.
Conclusions: No significant differences in patient satisfaction or major complications in UAE compared to surgical intervention. UAE is associated with an increased risk of surgical re-intervention.

  - GnRH agonist: leuprolide (Lupron®)
    - often used for 3 mo preoperatively to increase Hb and reduce fibroid size
    - reduces bleeding, shrinks fibroids, and corrects anemia
    - can be used long-term to bridge to menopause in combination with add-back progestin or estrogen
- interventional radiology approach: UAE occludes both uterine arteries, shrinks fibroids by 50% at 6 mo; improves heavy bleeding in 90% of patients within 1-2 mo; not an option in patients considering childbearing
  - higher risk of surgical re-intervention than with surgical approaches
  - should not be considered in patients planning future pregnancies due to potential for pregnancy complications
  - patients can become septic while fibroid is degenerating and require emergency hysterectomy
  - best for bleeding symptoms and NOT bulk
- surgical approach
  - myomectomy (hysteroscopic, open, or laparoscopic)
  - hysteroscopic resection of fibroid and endometrial ablation for AUB-Lsm (ablation should not be performed in patients planning future pregnancies)
  - hysterectomy (see *Hysterectomy, GY6*)
  - note: traditionally avoid operating on fibroids during pregnancy (due to vascularity and potential pregnancy loss); expectant management is usually best but more recently becoming more common

Contraception

- see Family Medicine, FM23

Table 7. Classification of Contraceptive Methods

Type	Effectiveness (Perfect Use, Typical Use*)
Physiological	
Withdrawal/coitus interruptus	96%, 77%
Rhythm	76%
Method/calendar/mucus/symptothermal	98% (first 6 mo postpartum)
Lactational amenorrhea	15%
Abstinence of all sexual activity	100%
Barrier Methods	
Condom alone	98%, 82%
Spermicide alone	82%, 72%
Sponge	
Parous	80%, 76%
Nulliparous	91%, 88%
Diaphragm with spermicide	94%, 88%
Female condom	95%, 79%
Cervical cap	
Parous	74%, 68%
Nulliparous	91%, 84%
Hormonal **Combined (Estrogen and Progesterone)**	
OCP	99.7%, 92%
NuvaRing®	99.7%, 92%
Transdermal (Ortho Evra®)	99.7%, 92%
Progesterone-Only	
Progestin-only injection (Depo-Provera®)	99.7%, 97%
Mirena® IUS	99.9%
Etonogestrel implant (NEXPLANON®)	99%
Copper IUS	99.3%
Surgical	
Tubal ligation	99.65%
Vasectomy	99.9%
Emergency Postcoital Contraception (EPC)	
Yuzpe® method	98% (within 24 h), decreases by 30% at 72 h
Plan B® levonorgestrel only	98% (within 24 h), decreases by 70% at 72 h
Postcoital IUD	99.9% (within 7 d)
Ella®	99.9% (within 7 d)

*Effectiveness: percentage of patients reporting no pregnancy after 1 yr of use

Counselling the Adolescent about Contraception
More than 80% of adolescent pregnancies are unintended. The one-year risk of pregnancy for patients engaging in contraception is 85%. The Canadian Paediatric Society endorses long-acting reversible contraceptives (LARCs; subdermal contraceptives and intrauterine contraceptives) as first line options for Canadian youth

Hormonal Methods

Combined Oral Contraceptive Pills
- daily pill with a 4-7 d placebo or pill free break to allow for withdrawal bleed. This is an apparent period, originally devised for women to hide contraception from others, and is not the same as menstruation (shorter pill free intervals result in fewer unintended pregnancies)
- estrogen: suppresses FSH and follicular development
- progestin: prevents LH surge, suppresses ovulation, thickens cervical mucus, decreases tubal motility, decidualizes endometrium
- most contain low dose ethinyl estradiol (10-35 μg) plus progestin (norethindrone, norgestrel, levonorgestrel, desogestrel, norgestimate, drospirenone). Pills vary by amount of ethinyl estradiol (maintains integrity of endometrium) and type of progestin (contraception action)
- failure rate (0.3-8.0%) depending on compliance
- monophasic formulations have the same amount of progestin throughout cycle while triphasic formulations have a varying amount of progestin throughout cycle
- can be prescribed for continuous or extended use. Continuous use involves taking a pill every day without using placebo pills, thus without withdrawal bleeding. Extended cycle preparations are also possible where withdrawal bleeds occur at less frequent intervals
- side effects: breast tenderness, nausea, bloating, unscheduled bleeding, amenorrhea. No clear evidence of weight gain
- risks: increased risk of venous thromboembolism, hypertension, and stroke in susceptible individuals. Unclear associations for elevated cancer risks
- non-contraceptive benefits: decreased menstrual bleeding, decreased acne, decreased progression of endometriosis as a result of inhibiting ovulation, decreased risk of ovarian and endometrial cancers

Transdermal (Ortho Evra®)
- patch that is changed every week for 3 consecutive weeks then left off for a week to allow for menstruation
- continuous release of norelgestromin 6 mg and ethinyl estradiol 0.60 mg into bloodstream
- can also be used in a continuous or extended fashion
- applied to lower abdomen, back, upper arm, buttocks, NOT breasts
- as effective as OCP in preventing pregnancy (>99% with perfect use)
- may be less effective in patients >90 kg
- side effects: irregular uterine bleeding (worse at initiation), local skin irritation, breast tenderness, uncommonly mood disturbances
- should not be used in patients with skin hypersensitivity, exfoliative dermatologic disorders, or patients treated for Hepatitis C with obmitasvir, paritaprevir or ritonavir due to risk of reducing efficacy of the contraceptive

Contraceptive Ring (Nuva Ring®)
- thin flexible plastic ring that is inserted into the vagina by the patient and left there for 3 wk then removed and discarded. A new ring is then inserted 7 d later to allow for menstruation; releases etonogestrel 120 μg/d and estradiol 15 μg/d
- can also be used in a continuous or extended fashion
- as effective as OCP in preventing pregnancy (98%)
- side effects: vaginitis, vaginal discharge, mild breast tenderness, mild nausea
- associated with less breakthrough bleeding than other methods
- risk of toxic shock is rare

Starting Hormonal Contraceptives
- thorough history and BP measurement (post-pandemic SOGC guidelines do not require BP reading anymore to allow for virtual appointments)
- pelvic exam not required as STI screening can be done by urine, and pap smear screening does not start until >25 yr
- can start at any time during cycle but ideally within 5 d of LMP
- follow-up visit 3 mo after hormonal contraceptives prescribed
- generally recommended to use back-up contraception for 7 d, particularly if initiated >5 days from LMP

Table 8. Combined Estrogen and Progestin Contraceptive Methods

Advantages	Side Effects	Contraindications
Highly effective Reversible Cycle regulation Decreased dysmenorrhea and heavy menstrual bleeding (less anemia) Decreased benign breast disease and ovarian cyst development Decreased risk of ovarian and endometrial cancer Increased cervical mucus which may lower risk of STIs Decreased PMS symptoms Less acne Osteoporosis protection (possibly) Patient controlled	**Estrogen-related** Nausea Breast changes (tenderness, enlargement) Fluid retention/bloating/edema Weight gain (rare) Migraine, headaches Thromboembolic events Liver adenoma (rare) Breakthrough bleeding (low estradiol levels) **Progestin-related** Amenorrhea/breakthrough bleeding Headaches Breast tenderness Increased appetite Decreased libido Mood changes HTN Acne/oily skin* Hirsutism* *Androgenic side effects may be minimized by prescribing formulations containing desogestrel, norgestimate, drospirenone, or cyproterone acetate	**Absolute** 4 wk postpartum (breastfeeding) or <21 d postpartum (not breastfeeding) Major surgery with prolonged immobilization Known/suspected pregnancy Undiagnosed abnormal vaginal bleeding Prior thromboembolic events, thromboembolic disorders (Factor V Leiden mutation; protein C or S, or antithrombin III deficiency), active thrombophlebitis Cerebrovascular or coronary artery disease Estrogen-dependent tumours (breast, uterus) Impaired liver function associated with acute liver disease Congenital hypertriglyceridemia Smoker age >35 yr Migraines with focal neurological symptoms (excluding aura) Uncontrolled HTN **Relative** Migraines (non-focal with aura <1 h) DM complicated by vascular disease SLE Controlled HTN Hyperlipidemia Sickle cell anemia Gallbladder disease **Drug Interactions/Risks** Rifampin, phenobarbital, phenytoin, griseofulvin, primidone, and St. John's wort can decrease efficacy of CHC requiring use of back-up method No evidence of fetal abnormalities if conceived on OCP No evidence that OCP is harmful to nursing infant but may decrease milk production

Table 9. Selected Examples of OCPs

Type	Active Compounds (estradiol and progestin derivative)	Advantages	Disadvantages
Lolo®	ethinyl estradiol 10 µg and norethindrone acetate 1 mg	Lowest estrogen dose (10 µg) OCP Least estrogen side effects 25% experience amenorrhea	Low-dose pills can often result in Low-dose pills can often result in breakthrough bleeding If this persists for longer than 3 mo, patient can be switched to an OCP with higher estrogen content Still effective with breakthrough bleeding
Alesse®	ethinyl estradiol 20 µg and levonorgestrel 0.5 mg	Low dose (20 µg) OCP Less estrogen side effects	Low-dose pills can often result in breakthrough bleeding If this persists for longer than 3 mo, patient can be switched to an OCP with higher estrogen content Still effective with breakthrough bleeding
Tri-cyclen®	ethinyl estradiol 35 µg and norgestimate 0.180/0.215/0.250 mg Triphasic oral contraceptive (graduated levels of progesterone)	Low androgenic activity can help with acne, as do all OCPs	Unlike monophasic OCP, triphasic OCPs cannot be used for continuous menstrual suppression as it will result in breakthrough bleeding
Yasmin® and Yaz®	Yasmin®: ethinyl estradiol 30 µg + drospirenone 3 mg (a new progestin) Yaz®: ethinyl estradiol 20 µg + drospirenone 3 mg – 24/4-d pill (4 d pill free interval) Drospirenone has antimineralocorticoid activity and antiandrogenic effects	Decreased perception of cyclic weight gain/bloating Fewer PMS symptoms Improved acne	Hyperkalemia (rare, contraindicated in renal and adrenal insufficiency) Check potassium if patient also on ACEI, ARB, K+-sparing diuretic, heparin

Missed Combined OCPs

Miss 1 pill in <24 h
- Take 1 pill ASAP, and the next pill at the usual time

Miss ≥1 pill in a row in 1st wk
- Take 1 pill ASAP, and continue taking 1 pill daily until the end of the pack
- Use back-up contraception for 7 d; EPC may be necessary

Miss <3 pills in 2nd or 3rd wk of cycle
- Take 1 pill ASAP, and continue taking 1 pill daily until the end of the pack
- Do not take placebo (28-d packs) or do not take a hormone free interval (21-d packs)
- Start the next pack immediately after finishing the previous one
- No need for back-up contraception

Miss ≥3 pills during the 2nd or 3rd wk
- Take 1 pill ASAP, and continue taking 1 pill daily until the end of the pack
- Do not take placebo (28-d packs) or do not take a hormone free interval (21-d packs)
- Start the next pack immediately after finishing the previous one
- Use back-up contraception for 7 d; EPC may be necessary

SOGC Committee Opinion on Missed Hormonal Contraceptives: New Recommendations. J Obstet Gynaecol Can 2008;30:1050-1062.

PROGESTIN-ONLY METHOD

Progestin-Only Pill

- progesterone-only pill taken daily with no pill free interval
- Slynd®: 4m g drospirenone - best for patients who need to avoid estrogen. Allows for 24 h missed-pill window. Formulated with 24 active pills and 4 placebo pills
- advantages: patient controlled, does not impact breast milk supply
- disadvantages: must take at exactly the same time every day so compliance can be challenging but has a 24 h missed pill window

Irregular breakthrough bleeding often occurs in the first few mo after starting OCP; usually resolves after three cycles

Progestin-only contraceptives must be taken at the same time every day

Progesterone Intrauterine System (IUS)

- small device left inside uterus typically left up to 5 yr, current FDA approved for up to 8 yrfor contraception
- Mirena IUS: levonorgestrel 52 µg - better for women patients with very heavy or painful periods, parous patients, 20% amenorrhea rate
- Kyleena IUS: levonorgestrel 19.5 µg - best for nulliparous people who want a light period every month and are mainly looking for birth control
- advantages: convenient, low hormone dose, minimal side effects, no effect on breast milk, quick return to fertility once removed
- disadvantages: insertion can be uncomfortable, must be inserted and removed by a doctor, rarely can have uterine perforation or IUS expulsion
- very effective reversible contraception; more likely to be an ectopic pregnancy if conception occurs due to efficacy at preventing intrauterine pregnancy. Lower absolute risk of ectopic pregnancy compared to other contraceptive methods

Depo-Provera®

- injectable depot medroxyprogesterone acetate 150 mg IM every 12 wk (convenient dosing)
- advantages: suppresses ovulation, complete amenorrhea in 70% of women after 1-2 yr of use, does not affect breast milk, effective for dysmenorrhea
- disadvantages: breakthrough bleeding, weight gain, controversial decreased bone density (often reversible), restoration of fertility may take up to 1-2 yr
- not recommended for long-term usage

Nexplanon®

- 4 cm long etonogestrel 68 mg implant that is placed in the inner arm and lasts for a maximum of 3 yr
- advantages: does not affect breast milk, do not have to put something in uterus, good bleeding and pain control, no change in bone density, quick return to fertility once removed
- disadvantages: breakthrough bleeding, weight gain

Table 10. Progestin-Only Contraceptive Methods

Indications	Mechanism of Action	Side Effects	Contraindications
Does not affect breast milk supply Women with contraindications to combined OCP (e.g. thromboembolic or myocardial disease) Women intolerant of estrogenic side effects of combined OCPs	Progestin prevents LH surge Thickening of cervical mucus Decreases tubal motility Endometrial decidualization Ovulation suppression – oral progestins do not consistently suppress ovulation compared to combined OCPs	Irregular menstrual bleeding Weight gain Headache Breast tenderness Mood changes Functional ovarian cysts Acne/oily skin Hirsutism	**Absolute** Current breast cancer Known/suspected pregnancy Undiagnosed vaginal bleeding Benign or malignant liver tumours, severe cirrhosis, or acute liver disease

Continuous or Extended Cycle vs. Cyclic Use of Combined Hormonal Contraceptives for Contraception
Cochrane Database Syst Rev 2014:7
Purpose: Systematic review of RCTs assessing the efficacy and side effects of cyclic administration vs. extended use (longer periods of active pills and/or shorter periods placebo) or continuous use (uninterrupted active pill administration) of combination oral contraceptives (COC).
Results: The initial review published in 2012 identified 12 RCTs that ultimately showed no difference between groups with regards to efficacy (pregnancy rates), safety, and compliance rates. Continuous or extended COCs were shown to reduce menstrual symptoms (headaches, tiredness, bloating, and menstrual pain). In addition, 11 of 12 studies reported similar or improved bleeding patterns with continuous or extended cycles.
Conclusions: This recently published updated systematic review identified a further 4 RCTs, however, results did not change.

Intrauterine Device

Table 11. IUS Contraceptive Methods

Mechanism of Action	Benefits of all IUS	Risks of all IUS	Side Effects	Contraindications
Copper-Containing IUS (Nova-T®): mild foreign body reaction in endometrium, toxic to sperm and alters sperm motility **Progesterone-Releasing IUS (Mirena®, Kyleena®):** decidualization of endometrium and thickening of cervical mucus; minimal effect on ovulation	Return to baseline fertility after removal is very fast No estrogen (doesn't affect breastfeeding, can use if smoker, hypertension, previous VTE) Lasts 5 yr but can be removed before that if desired Can insert immediately after placental delivery and post abortion	Insertion is uncomfortable Must be inserted and removed by a doctor Infection (especially if multiple partners and within first 10 d of insertion) Uterine wall perforation on insertion (1/10000) Expulsion (5% in the 1st yr, greatest in the 1st mo) Chance of pregnancy very low, but if pregnant, higher relative risk of an ectopic pregnancy or miscarriage IUS do not protect against STIs*	**Copper IUS:** increased blood loss and duration of menses, dysmenorrhea, increased vaginal discharge **Progesterone IUS:** spotting, bloating, headache, acne, breast tenderness, nausea, headaches, ovarian cyst formation, vaginal discharge, and/or mood changes. Usually very mild	**Absolute** **Both Copper and Progesterone IUS** Known or suspected pregnancy Undiagnosed genital tract bleeding Acute or chronic PID Lifestyle risk for STIs Known distorted uterine cavity Immediately post-septic abortion **Copper IUS** Known allergy to copper or Wilson's disease **Relative** **Both Copper and Progesterone IUS** Valvular heart disease PMHx of PID or ectopic pregnancy Presence of prosthesis Abnormalities of uterine cavity Intracavitary fibroids Cervical stenosis Immunosuppressed individuals (e.g. HIV) Abnormalities of uterine cavity (excluding distorted uterine cavity) Copper IUS – severe dysmenorrhea or heavy menstrual bleeding

*Cervical swabs for gonorrhea and chlamydia should be done prior to insertion

Emergency Postcoital Contraception

Table 12. Emergency Postcoital Contraceptive (EPC) Methods

Method	Mechanism of Action	Side Effects	Contraindications
HORMONAL			
Yuzpe Method Ovral® 2 tablets then repeat in 12 h (ethinyl estradiol 100 µg levonorgestrel 500 µg) Can substitute with any OCP as long as it contains ethinyl estradiol 100 µg 2% overall risk of pregnancy Used within 72 h of unprotected intercourse ideally within 24 h intercourse, limited evidence of benefit up to 5 d Efficacy decreased with time (e.g. less effective at 72 h than 24 h)	Unknown; theories include: Suppresses ovulation or causes deficient luteal phase Alters endometrium to prevent implantation Affects sperm/ova transport	Nausea (due to estrogen; treat with Gravol®) Irregular spotting	Pre-existing pregnancy (although not teratogenic) Caution in women with contraindications to OCP (although no absolute contraindications)
"Plan B™" Use within 72 h of unprotected intercourse, can use up to 5 d after levonorgestrel 750 µg q12 h for 2 doses (can also take 2 doses together) Greater efficacy (75-95% if used within 24 h) and better side effect profile than Yuzpe method No estrogen thus very few contraindications/side effects (less nausea) Less effective if >75 kg, not recommended if >80 kg	Same as above	Same as above	Same as above but no caution in women with contraindications to OCP
Ulipristal (Ella™) 30 mg PO within 5 d of unprotected intercourse	Selective Progesterone Receptor Modulator (SPRM) with primarily antiprogestin activity: may delay ovulation by up to 5 d	Headache, hot flashes, constipation, vertigo, endometrial thickening	Same as above but no caution in women with contraindications to OCP Need to delay the restart of Combined OCP by 14 d
NON-HORMONAL			
Postcoital IUD (Copper) Insert up to 7 d postcoitus Prevents implantation 1% failure rate Can use for short duration in higher risk individuals	See *Table 11*, GY18	See *Table 11*, GY18	See *Table 11*, GY18

Follow-up
- 3-4 wk post treatment to confirm efficacy (confirmed by spontaneous menses or pregnancy test)
- contraception counselling

Termination of Pregnancy

Indications
- patient desires an end to pregnancy
- may be for medical reasons (health of patient, disorders of pregnancy, or fetal anomaly) or a variety of social reasons, including patient

Legal Considerations
- no current law in Canada concerning abortion. Access to abortion is provincially regulated and highly variable
- CPSO: a physician must provide a referral for abortion services regardless of personal beliefs, but is not compelled to personally perform the procedure

Rates
- 13.1 abortions in 1000 women 15-44 yr in Canada (2017 CIHI data)
- worldwide: 56 million induced abortions per yr; half are unsafe (WHO data)
- maternal mortality almost zero where induced abortion is safe and legal; rises to 100 maternal deaths in 100000 live births in sub-Saharan Africa and other countries where abortion is illegal and unsafe
- in Canada, 91% of induced abortions occur <12 wk GA; much less common after 24 wk GA (usually only for maternal/fetal reasons)

Methods of Induced Abortion
- medical
  - gold standard up to 9 wk GA
  - mifepristone and misoprostol 95-98% effective up to 49 d after LMP
  - mifepristone (200 mg PO on 1st d) blocks the progesterone receptor (progesterone required in early pregnancy), alters the endometrium, induces bleeding and causes the cervix to soften
  - misoprostol (800 mg PV/BUC on 2nd or 3rd d) is a synthetic prostaglandin that stimulates uterine contractions and expulsion of the products of conception
  - can also use misoprostol alone or methotrexate and misoprostol (with lower success rates of 90-95%)

- good follow-up and back-up access to D&C required if medical abortion fails
- side effects: bleeding (self-limited) and pain (while tissue passes) are expected side effects, as well as nausea, diarrhea, and chills/fever due to prostaglandin effects
- contraindications:
  - absolute: ectopic pregnancy, chronic adrenal failure, ambivalence
  - relative: unconfirmed GA, IUD in situ, long term steroid therapy, bleeding disorder/anticoagulation, porphyria
- between 14-24 wk GA medical induction of labour (misoprostol followed by oxytocin) is an option, whereas after 24 wk GA induction of labour is the only option

- surgical
  - <14 wk GA:
    - manual vacuum aspiration – up to 12 wk GA with handheld aspiration device
    - suction dilatation + aspiration ± curettage – may involve presurgical preparation of cervix with laminaria tents and/or misoprostol
  - 14-24 wk GA:
    - dilatation and evacuation - presurgical preparation of cervix required with laminaria tents
  - pain or discomfort during procedure mitigated by use of appropriate analgesia/sedation/anesthesia (including paracervical blocks)
  - rare complications (1-5%): laceration of cervix, infection/endometritis, retained products of conception, ongoing pregnancy
  - very rare complications (0.1-2%): hemorrhage, perforation of uterus, Asherman's syndrome (adhesions within the endometrial cavity causing amenorrhea/infertility), future preterm birth (controversial and likely only with repeated abortion)
- counselling
  - counselling options always provided including possibility of carrying pregnancy with/without adoption
  - offer future contraception (most effective way to prevent unintended pregnancies) and family planning services
  - ensure follow-up

Pregnancy-Related Complications

First Trimester Bleeding

Prevalence
- first trimester (T1) vaginal bleeding or spotting is common, occurring in 25% of pregnancies

Approach to the Patient with Bleeding in First Trimester

History
- risk factors for ectopic pregnancy (see *Ectopic Pregnancy, GY21*)
- previous spontaneous abortion
- recent trauma
- characteristics of the bleeding (including any tissue passed)
- characteristics of the pain (cramping pain suggests spontaneous abortion)
- history of coagulopathy
- gynecological/obstetric history
- fatigue, dizziness, syncopal episodes due to hypovolemia, fever (may be associated with septic abortion)

Physical
- vitals (including orthostatic changes)
- abdomen (symphysis fundal height, tenderness, presence of contractions)
- perineum (signs of trauma, genital lesions)
- speculum exam (cervical os open or closed, presence of active bleeding/clots/tissue)
- pelvic exam (uterine size, adnexal mass, uterine/adnexal tenderness, cervical motion tenderness)

Investigations
- β-hCG
- U/S (confirm intrauterine pregnancy and fetal viability)
- CBC
- group and screen

Treatment
- IV resuscitation for hemorrhagic shock
- treat the underlying cause

Bleeding in Pregnancy Definitions

First trimester bleeding: vaginal bleeding within the first 14 wk

Second trimester bleeding: 14-28 wk

Differential Diagnosis

Physiologic bleeding: spotting, due to implantation of placenta – reassure and check serial β-hCGs

Abortion (threatened, inevitable, incomplete, complete)

Abnormal pregnancy (ectopic, molar) (see *Hydatidiform Mole, GY53*)

Trauma (post-coital or after pelvic exam)

Genital lesion (e.g. cervical polyp, neoplasms)

Subchorionic hematoma

Non-OB/GYN related cause of bleeding (e.g. hemorrhoids)

Every woman of childbearing age presenting to ER with abdominal or pelvic pain should have β-hCG measured

Spontaneous Abortions

- see *Termination of Pregnancy, GY19* for therapeutic abortions

Table 13. Classification of Spontaneous Abortions

Type	History	Clinical and U/S Findings	Management (± Rhogam®)
Threatened	Bleeding ± cramping	Live fetus on U/S Cervix closed	Watch and wait <5% will go on to abort
Inevitable	Bleeding and cramping ± rupture of membranes	Fetus low in uterus on U/S Cervix open	a) Watch and wait b) Misoprostol 800 µg PV now and 800 µg PV 24 h later c) D&C
Incomplete	Bleeding and cramps ± passage of tissue noticed	Residual tissue in uterus on U/S Cervix open	a) Watch and wait b) Misoprostol 800 µg PV now and 800 µg PV 24 h later c) D&C
Complete	Bleeding and complete passage of sac and placental tissue	Empty uterus on U/S Cervix closed, no bleeding	No management needed
Missed	No bleeding (fetal death in utero)	No fetal heart rate on U/S, fetus and sac still in uterus Cervix closed, no bleeding	a) Watch and wait b) Mifepristone 200 mg PO followed by misoprostol 800 µg PV 24 h later c) D&C
Recurrent	≥3 consecutive spontaneous abortions		Evaluate mechanical, genetic, environmental, and other risk factors
Septic	Contents of uterus infected – very rare	Tissue in uterus on U/S Foul discharge	a) IV broad spectrum antibiotics b) D&C 24 h after antibiotics c) Misoprostol 800µg PV 24 h later

Management of Abortions

Always rule out an ectopic pregnancy

Always check Rh; if negative, give Rhogam®

Always ensure patient is hemodynamically stable

Pregnancy failure can be diagnosed on U/S based on findings of crown-rump length ≥7 mm and no heartbeat, mean sac diameter of ≥7 mm and no embryo, absence of embryo with heartbeat ≥2 wk after a scan that showed a gestational sac without a yolk sac, or absence of embryo with heartbeat ≥11 d after a scan that showed a gestational sac with a yolk sac

Ectopic Pregnancy

Definition

- embryo implants outside of the endometrial cavity

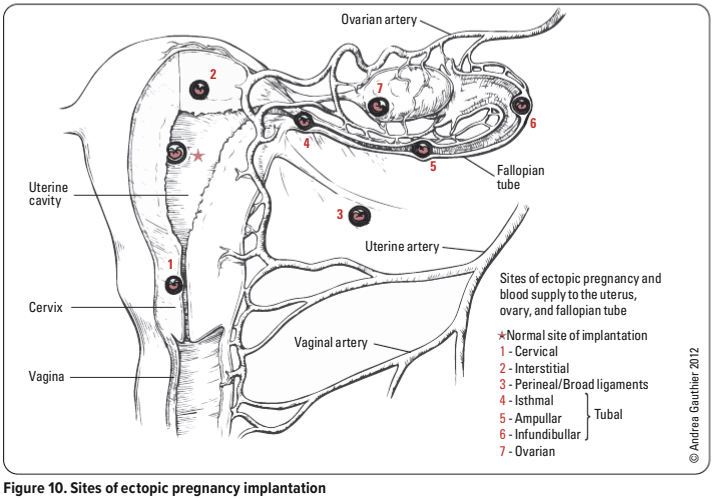

Figure 10. Sites of ectopic pregnancy implantation
ampullary (70%) >> isthmal (12%) > fimbrial (11%) > ovarian (3%) > interstitial (2%) > abdominal (1%)

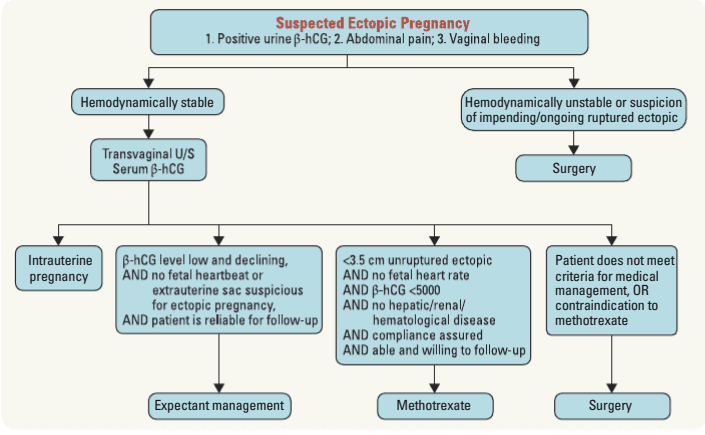
Epidemiology

- 1/100 pregnancies
- fourth leading cause of maternal mortality, leading cause of maternal death in first trimester
- increase in incidence over the last 3 decades
- three commonest locations for ectopic pregnancy: ampullary (70%), isthmic (12%), fimbrial (11%)

Etiology

- 50% due to damage of fallopian tube cilia following PID
- intrinsic abnormality of the fertilized ovum
- conception late in cycle

- transmigration of fertilized ovum to contralateral tube
- major cause is disruption of normal tubal anatomy (infection, surgery, congenital differences, tumours)



Suspected Ectopic Pregnancy
1. Positive urine β-hCG; 2. Abdominal pain; 3. Vaginal bleeding
Hemodynamically stable
Hemodynamically unstable or suspicion of impending/ongoing ruptured ectopic
Transvaginal U/S Serum β-hCG
Surgery
Intrauterine pregnancy
β-hCG level low and declining, AND no fetal heartbeat or extrauterine sac suspicious for ectopic pregnancy, AND patient is reliable for follow-up
<3.5 cm unruptured ectopic AND no fetal heart rate AND β-hCG <5000 AND no hepatic/renal/ hematological disease AND compliance assured AND able and willing to follow-up
Patient does not meet criteria for medical management, OR contraindication to methotrexate
Expectant management
Methotrexate
Surgery

Figure 11. Algorithm for suspected ectopic pregnancy

Risk Factors

- previous ectopic pregnancy
- gynecologic
  - current IUD use – overall risk of pregnancy very low, but increased risk of ectopic pregnancy if pregnancy occurs
  - history of PID (especially infection with *C. trachomatis*), salpingitis, gonorrhea, chlamydia
  - infertility
- infertility treatment (IVF pregnancies following ovulation induction (7% ectopic rate))
- previous procedures
  - any surgery on fallopian tubes (for previous ectopic pregnancy, tubal ligation, tubal reconstruction, etc.)
  - abdominal surgery for ruptured appendix, etc.
- smoking
- structural
  - uterine leiomyomas
  - adhesions
- *in utero* diethylstilbestrol (DES) exposure
- regular vaginal douching
- increased age

Investigations

- serial β-hCG levels; normal doubling time with intrauterine pregnancy is every 48 h in the first 8 wk
  - rise in β-hCG <35% every two days across 3 measurements is consistent with a non-viable pregnancy
  - prolonged doubling time, plateau, or decreasing levels before 8 wk implies nonviable gestation but does not provide information on location of implantation
  - 85% of ectopic pregnancies demonstrate abnormal β-hCG doubling
- ultrasound
  - extra-uterine gestational sac with a yolk sac or embryo, regardless of cardiac activity, is diagnostic
  - specific suggestive, but not diagnostic, finding on transvaginal U/S is a tubal ring
- suspect ectopic pregnancy in case of empty uterus by transvaginal U/S with β-hCG >2000-3000 mIU/mL
- laparoscopy (sometimes used for definitive diagnosis)

Treatment

- goals of treatment: conservative (preserve tube if possible), maintain hemodynamic stability
- surgical = laparoscopy
  - linear salpingostomy an option if tube salvageable, however, patient must be reliable to follow-up with weekly β-hCG
  - 15% risk of persistent trophoblast if salpingostomy, must monitor β-hCG titres weekly until they reach non-detectable levels
  - salpingectomy if tube damaged or ectopic is ipsilateral recurrence

Contraindications to Methotrexate Therapy in the 2021 SOGC Clinical Practice Guidelines on Management of Pregnancy of Unknown Location, Tubal and Nontubal Ectopic Pregnancies.
J Obs Gyn Can 2021; 43(5): 614-630

1. Hemodynamic instability or any signs of hemorrhage or tubal rupture
2. Unwilling or unable to adhere to methotrexate protocol and follow-up
3. Clinically significant abnormalities in renal or liver function
4. Hematologic disorders or bone marrow suppression
5. Active pulmonary disease
6. Peptic ulcer disease
7. Hypersensitivity to methotrexate
8. Immunosuppression or immunodeficiency
9. Chronic infection
10. Heterotopic pregnancy with coexisting viable intrauterine pregnancy
11. Breastfeeding

Note - cannot conceive for 3 mo after methotrexate therapy due to high teratogenicity

Salpingostomy Versus Salpingectomy in Women with Tubal Pregnancy (ESEP study): An Open-Label, Multicentre, Randomized Controlled Trial
Lancet 2014; 383:1483-1487

Purpose: Determine whether tube preserving salpingostomy offers favorable future fertility compared to salpingectomy in patients surgically treated for tubal pregnancies.
Methods: In this international RCT, patients with confirmed tubal pregnancy and healthy contralateral tube were randomized to salpingostomy (n=215) and salpingectomy (n=231). The primary outcome was ongoing pregnancy by natural conception.
Results: The primary outcome was present in 60.7% of patients in the salpingostomy group and 56.2% of patients in the salpingectomy group (p = 0.678). Persistent trophoblast was more frequent in the salpingostomy group with 7% of patients compared to <1% of patients in the salpingectomy group.
Conclusions: For pregnant patients requiring surgical treatment for tubal pregnancy, and that have a healthy contralateral tube, salpingostomy does not increase fertility prospects.

DDx of Lower Abdominal Pain
Urinary tract: UTI, kidney stones
GI: diverticulitis, appendicitis
Gynecological: endometriosis, PID, fibroid (degenerating, infarcted, torsion), ovarian torsion, ovarian neoplasm, ovarian cyst, pregnancy-related

Any patient with a uterus presenting with abdominal pain, vaginal bleeding, and amenorrhea is an ectopic pregnancy until proven otherwise

More than half of patients with ectopic pregnancy have no risk factors

- consider Rhogam® if Rh-negative
- patient may require laparotomy if unstable, extensive abdominal surgical history, etc.

- medical = methotrexate
  - folic acid reductase inhibitor affecting rapidly dividing cells
  - use 50 mg/m²body surface area; given as a one time IM dose
  - this is 1/5 to 1/6 chemotherapy dose, therefore minimal side effects (reversible hepatic dysfunction, diarrhea, gastritis, dermatitis)
  - follow β-hCG levels on days 4 and 7 after injection, and then weekly until β-hCG is non-detectable
  - plateaued or rising levels suggest persistent trophoblastic tissue requiring further treatment
  - 82-95% success rate, but up to 25% will require a second dose
  - administer a second dose if β-hCG does not decrease by at least 15%
  - tubal patency following methotrexate treatment approaches 80%
  - stop prenatal vitamins as folic acid will decrease efficacy of methotrexate
- expectant management is an option for patients who are clinically stable, reliable for follow-up, understand the risk of tubal rupture, and have β-hCG levels that are low and declining

Presentation of Ectopic Pregnancy Ruptures

Acute abdomen with increasing pain

Abdominal distention

Shock

Prognosis

- 9% of maternal deaths during pregnancy attributed to ectopic pregnancy
- 40-60% of patients will become pregnant again after surgery
- 10-20% will have subsequent ectopic pregnancy

Infertility

Epidemiology

- 10-15% of couples, must investigate both members of the couple

Female Factors

Infertility: inability to conceive or carry to term a pregnancy after 1 yr of regular, unprotected intercourse
Primary infertility: infertility in the context of no prior pregnancies
Secondary infertility: infertility in the context of a prior conception
Generally, 75% of couples achieve pregnancy within 6 mo, 85% within 1 yr, 90% within 2 yr

Etiology

- increasing age
- chemotherapy
- ovulatory dysfunction (15-20%)
  - three groups of ovulatory disorders
    - hypogonadotropic hypogonadal (hypo-hypo; low gonadotropins, low gonadal hormones) anovulation (5-10%): excessive exercise, low body weight
    - normogonadotropic normoestrogenic anovulation (70-85%): PCOS
    - hypergonadotropic hypoestrogenic anovulation (10-30%): primary gonadal failure, gonadal dysgenesis
  - hypothalamic (hypothalamic amenorrhea)
    - stress, poor nutrition, excessive exercise (even with presence of menstruation), history of eating disorders
  - pituitary (prolactinoma, hypopituitarism)
  - ovarian
    - PCOS
    - primary ovarian insufficiency
    - luteal phase defect (poor follicle production, premature corpus luteum failure, failed uterine lining response to progesterone), poorly understood
  - systemic diseases (thyroid, diabetes, Cushing's syndrome, renal/hepatic failure)
  - congenital (Turner's syndrome, gonadal dysgenesis, gonadotropin deficiency)
- outflow tract abnormality (15-20%)
  - tubal factors (20-30%)
    - PID
    - adhesions (previous surgery, peritonitis, endometriosis)
    - ligation/occlusion (previous ectopic pregnancy)
- uterine factors (<5%)
  - congenital anomalies, bicornuate uterus, septate uterus, prenatal DES exposure, intrauterine adhesions (e.g. Asherman's syndrome), submucosal fibroids/polyps
  - infection (endometritis, pelvic tuberculosis)
- cervical factors (5%)
  - hostile or acidic cervical mucus, anti-sperm antibodies
  - structural defects (cone biopsies, laser or cryotherapy)
- endometriosis (15-30%)
- multiple factors (30%)
- unknown factors (10-15%)

When Should Investigations Begin?

- <35 yr: after 1 yr of regular unprotected intercourse
- 35-40 yr: after >6 mo of regular unprotected intercourse
- >40 yr: immediately

Earlier if:

- History of PID
- History of infertility in previous relationship
- Prior pelvic surgery
- Chemotherapy/radiation in either partner
- Recurrent pregnancy loss
- Moderate-severe endometriosis

Investigations

- ovarian factors
  - day 3: FSH, LH, estradiol, TSH, prolactin, free and total testosterone, androstenedione, DHEAS, free testosterone
  - day 21-23: high serum progesterone levels confirm ovulation

Ethical Considerations in Infertility Treatment

Infertility demands non-judgmental discussion

Ethical issues surrounding surrogacy, donor gametes, and other advanced reproductive technologies are still evolving and remain controversial

If the physician finds that certain treatment options lie outside of their moral boundaries, the infertile couple should be referred to another physician

- general health: CBC, Fe, HbA1c
- any day of cycle: anti-mullerian hormone (AMH) – a test of ovarian reserve, the higher the number the better

• tubal factors
- hysterosalpingogram (HSG) – dye insufflated into uterus and x-ray taken
  - shows uterine cavity shape and if tubes are patent
  - can be therapeutic – opens fallopian tube
- sonohysterogram (SHG) – saline insufflated into uterus and U/S done
  - shows uterine cavity shape and if tubes are patent
  - can be therapeutic and opens the tubes
- laparoscopy with dye insufflation (or tubal dye test) rarely done as diagnostic

• peritoneal/uterine factors
- HSG/SHG, hysteroscopy

• other
- karyotype

Treatment

• lifestyle modifications (quit smoking/cannabis, reduce caffeine/alcohol intake, healthy diet, exercise, etc.)
- education: time intercourse relative to ovulation (have sex every other day from 4 d prior to 2 d following presumed ovulation)

• medical
- ovulation induction
  - clomiphene citrate (Clomid®): estrogen antagonist used in anovulatory patients
    - blocks brain's perception of circulating estrogen, resulting in increased release of FSH and LH which can help to induce ovulation (better results if anovulatory)
  - letrozole: aromatase inhibitor; may be associated with a higher rate of live births in patients with PCOS
- may add:
  - bromocriptine (dopamine agonist) or carbamazepine (anticonvulsant) if elevated prolactin
  - metformin (for PCOS)
  - luteal phase progesterone supplementation for luteal phase defect (mechanism not completely understood)
  - anticoagulation and ASA (81 mg PO once daily) for women with a history of recurrent spontaneous abortions (for antiphospholipid antibody syndrome)
  - thyroid replacement to keep TSH <2.5

• procedural
- artificial insemination: intracervical insemination (ICI), intrauterine insemination (IUI), intrauterine tuboperitoneal insemination (IUTPI), intratubal insemination (ITI)
- sperm washing
- IVF
- intrafallopian transfer (IFT)
- GIFT*: immediate transfer with sperm after oocyte retrieval
- ZIFT*: transfer after 24 h culture of oocyte and sperm
- TET*: transfer after >24 h culture
- ICSI
- IVM
- ± oocyte or sperm donors
- ± pre-genetic screening for single gene defects in karyotype of zygote
- hysteroscopy

*not performed in Canada

• surgical
- salpingectomy
- tubuloplasty (extremely rare)
- lysis of adhesions

Male Factors

- see Urology, U24

Etiology

- varicocele (>40%)
- idiopathic (>20%)
- obstruction (~15%)
- cryptorchidism (~8%)
- immunologic (~3%)
- exogenous androgens

Investigations

- semen analysis and culture

Normal Semen Analysis (WHO lower reference limits)
- Must be obtained after 2-7 d of abstinence
- Volume 1.5 cc
- Count 15 million/cc
- Vitality 58% live
- Motility 32% progressive, 40% total (progressive + non-progressive)
- Morphology 4.0% normal

Polycystic Ovarian Syndrome

Etiology

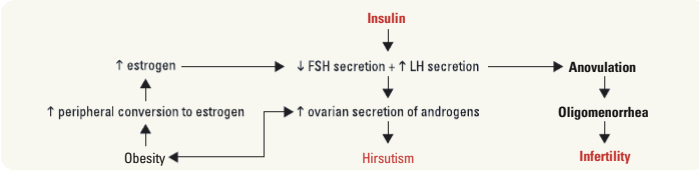


Figure 12. Pathophysiology of polycystic ovarian syndrome

Diagnosis

- Rotterdam diagnostic criteria: 2 of 3 required
  - oligomenorrhea/irregular menses for 6 mo
  - hyperandrogenism
    - clinical evidence – hirsutism or acne
    - biochemical evidence – raised free testosterone
  - polycystic ovaries on U/S (not appropriate in adolescents)

Clinical Features

- average age 15-35 yr at presentation
- in adolescents, wait at least 1-2 yr to make diagnosis as adolescence resembles PCOS
- abnormal/irregular uterine bleeding, hirsutism, infertility, obesity, virilization
- acanthosis nigricans: darkening of skin folds in intertriginous zones (indicative of insulin resistance)
- insulin resistance occurs in both lean and obese patients
- FHx of DM

Investigations

- assess BMI, BP, and fasting lipid profile at presentation
  - goal: identify hyperandrogenism or chronic anovulation and rule out specific pituitary or adrenal disease as the cause
- laboratory
  - prolactin, TSH, free T4
  - 17-hydroxyprogesterone, LH:FSH >2:1 (LH is chronically high with FSH mid-range or low (low sensitivity and specificity))
  - increased DHEAS, androstenedione, and free testosterone (most sensitive)
- transvaginal or transabdominal U/S: polycystic-appearing ovaries
  - "string of pearls" – 12 small follicles 2-9 mm or increased ovarian volume (>10 cc)
- tests for insulin resistance or glucose tolerance
  - 75 g OGTT every other year (particularly if obese)
- consider endometrial biopsy if long-standing abnormal uterine bleeding to rule out hyperplasia
- rule out other causes of abnormal bleeding

Treatment

- cycle control
  - lifestyle modification (decrease BMI, increase exercise) to decrease peripheral estrone formation
  - hormonal IUS, combined hormonal contraception or cyclic Provera® to prevent endometrial hyperplasia due to unopposed estrogen
  - oral hypoglycemic (e.g. metformin) if T2DM or if trying to become pregnant
  - tranexamic acid (Cyklokapron®) for menorrhagia only
- infertility
  - medical induction of ovulation: letrozole, clomiphene citrate, human menopausal gonadotropins (HMG (Pergonal®)), LHRH, recombinant FSH, and metformin
    - metformin may be used in conjunction with clomiphene citrate for ovulation induction
  - ovarian drilling (perforate the stroma), wedge resection of the ovary - rarely done
  - bromocriptine (if hyperprolactinemia)
- hirsutism
  - any OCP can be used
    - Diane 35® (cyproterone acetate): antiandrogenic
    - Yasmin® (drospirenone and ethinyl estradiol): spironolactone analogue (inhibits steroid receptors)
  - mechanical removal of hair
  - finasteride (5-α reductase inhibitor)
  - flutamide (androgen reuptake inhibitor)
  - spironolactone (androgen receptor inhibitor)

Polycystic Ovarian Syndrome
HHAIIR-AN
Hirsutism, **H**yper**A**ndrogenism, **I**nfertility, **I**nsulin **R**esistance, **A**canthosis **N**igricans

PCOS may be confused with
- Late onset CAH (21-hydroxylase deficiency)
- Cushing's syndrome
- Ovarian and adrenal neoplasms
- Hyperprolactinemia
- Hypothyroidism

Clinical Signs of Endocrine Imbalance
- Menstrual disorder/amenorrhea (80%)
- Infertility (74%)
- Hirsutism (69%)
- Obesity (49%)
- Impaired glucose tolerance (35%)
- DM (10%)

Long-Term Health Consequences
- Hyperlipidemia
- Adult-onset DM
- Endometrial hyperplasia
- Subfertility
- Obesity
- Sleep apnea

Diagnostic Criteria for Polycystic Ovary Syndrome: Pitfalls and Controversies
J Obstet Gynaecol Can 2008;8:671-679
At present, there is no clear-cut definition of biochemical hyperandrogenemia, particularly since there is dependence on poor laboratory standards for measuring androgens in women. Clinical signs of hyperandrogenism are ill-defined in women with PCOS, and diagnosis of both hirsutism and polycystic ovarian morphology remains subjective. There is also the inappropriate tendency to assign ovulatory status solely on the basis of menstrual cycle history or poorly timed endocrine measurements. Therefore it is important as clinicians to recognize the multifactorial and complex nature of PCOS and place this in the context of our present diagnostic limitations.

Gynecological Infections

Physiologic Discharge

- clear, white, flocculent, odourless discharge; pH 4.0-4.5
- smear contains epithelial cells, Lactobacilli
- increases with increased estrogen states: pregnancy, OCP, mid-cycle, PCOS, or premenarchal
- if increased in perimenopausal/postmenopausal woman, consider investigation for other effects of excess estrogen (e.g. endometrial cancer)

Non-Physiologic Discharge

- etiology
  - genital tract infection
  - vulvovaginitis: candidiasis, trichomoniasis, BV, polymicrobial superficial infection
  - chlamydia, gonorrhea
  - pyosalpinx, salpingitis
  - genital tract inflammation (non-infectious)
  - local: chemical irritants, douches, sprays, foreign body, trauma, atrophic vaginitis, desquamative inflammatory vaginitis, focal vulvitis
  - neoplasia: vulvar, vaginal, cervical, endometrial
  - systemic: toxic shock syndrome, Crohn's disease, collagen vascular disease, dermatologic (e.g. lichen sclerosis)
  - IUD, OCP (secondary to progesterone)

Vulvovaginitis

PREPUBERTAL VULVOVAGINITIS

- clinical features: irritation, pruritus, discharge, vulvar erythema, vaginal bleeding (can be due to Group A *Streptococcus* and *Shigella*)
- etiology
  - non-specific vulvovaginitis is responsible for 25-75% of vulvovaginitis in prepubertal patients
  - there are a number of potential factors in children that increase the risk of vulvovaginitis:
    - lack of labial development
    - non-estrogenized, thin mucosa
    - more alkaline pH (pH >7) than postmenarchal patients
    - obesity
    - poor hygiene (proximity of anus to vagina)
    - foreign bodies (most commonly toilet paper)
    - irritation by bubble baths, shampoos, perfumed soaps, and chemicals
  - localized skin disorders: lichen sclerosis, condyloma acuminata
  - trauma: accidental straddle injury, sexual abuse
  - infectious
    - pinworms
    - *Candida* (if using diapers or chronic antibiotics)
    - Group A *Streptococcus, S. aureus*, and *Shigella*
    - discovery of STI should raise suspicion of sexual abuse
  - other
    - polyps, tumour (ovarian malignancy)-RARE
    - psychosomatic vaginal complaints (specific to vaginal discharge)
    - endocrine abnormalities (specific to vaginal bleeding)
    - blood dyscrasia (specific to vaginal bleeding)
    - other systemic diseases: measles, chickenpox, scarlet fever, Epstein-Barr Virus, *Mycoplasma* pneumonia-induced rash and mucositis, Stevens-Johnson syndrome, Crohn's disease, and Kawasaki disease have all been associated with vulvovaginal signs and symptoms
- investigations
  - vaginal swab for culture (specifically state that it is a pre-pubertal specimen)
  - pH, wet-mount, and KOH smear in postpubertal adults only
- treatment
  - enhanced hygiene and local measures (handwashing, white cotton underwear, use sitz baths, use mild detergent, urinate with legs spread apart, no nylon tights, no tight-fitting clothes, no sleeper pajamas, avoid bubble baths, eliminate fabric softener, avoid prolonged exposure to wet bathing suits) to protect vulvar skin
  - infectious: treat with antibiotics for organism identified

Vulvovaginitis
Vulvar and vaginal inflammation

Vulvar Hygiene
Recommend wipe front to back, wash vulva only with water, avoid daily pantyliners, avoid douching, no need for "feminine cleansers/sprays/powders," use gentle laundry detergents for underwear, cotton underwear, no underwear at night

Prepubertal and Adolescent Gynecological Infections: Legal Aspects of Confidentiality

Clinicians who treat adolescents must be aware of federal, state, and provincial laws related to adolescent consent and confidentiality

Clinicians must be aware of guidelines governing funding sources for particular services and be familiar with the consent and confidentiality policies of the facility in which they practice

Most common gynecological problem in prepubertal patients is non-specific vulvovaginitis, not yeast

Table 14. Other Common Causes of Vulvovaginitis in Prepubertal Girls

	Pinworms	Lichen Sclerosis	Foreign Body
Diagnosis	Cellophane tape test	Area of white patches and thinning of skin (figure of 8)	Careful examination with or without sedation
Treatment	Empirical treatment with mebendazole (anthelmintic)	Topical steroid creams	Irrigation of vagina with saline, may require local anesthesia or an exam under anesthesia

INFECTIOUS VULVOVAGINITIS

Table 15. Infectious Vulvovaginitis

	Candidiasis	Bacterial Vaginosis (BV)	Trichomoniasis
Organisms	*Candida albicans* (90%) *Candida glabrata* (<5%) *Candida tropicalis* (<5%)	Replacement of vaginal Lactobacillus with: *Gardnerella vaginalis* *Mycoplasma hominis* *Anaerobes: Prevotella, Mobiluncus, Bacteroides*	*Trichomonas vaginalis* (flagellated protozoan)
Risk Factors	Immunosuppression (DM, AIDS, etc.) Recent antibiotic use Increased estrogen levels (e.g. pregnancy, OCP)	High frequency of vaginal intercourse Smoking Douching	Sexual transmission
Discharge	Whitish, "cottage cheese," minimal	Grey, thin, diffuse, fishy smelling	Yellow-green, malodourous, diffuse, frothy
% asymptomatic	20% asymptomatic	50-75% asymptomatic	25% asymptomatic
Signs/Symptoms	Intense pruritus Swollen, inflamed genitals Vulvar burning, dysuria, dyspareunia	Fishy odour, especially after coitus Absence of vulvar/vaginal irritation	Petechiae on vagina and cervix Occasionally irritated, tender vulva Dysuria, frequency, dyspareunia
pH	≤4.5	≤4.5	≤4.5
Saline Wet Mount	KOH wet mount reveals hyphae and spores	>20% clue cells = squamous epithelial cells dotted with coccobacilli (*Gardnerella*) Paucity of WBC Paucity of Lactobacilli Positive whiff test: fishy odour with addition of KOH to slide (due to formation of amines)	Motile flagellated organisms Many WBC Inflammatory cells (PMNs) Can have positive whiff test
Treatment	Clotrimazole, butoconazole, miconazole, terconazole suppositories, and/or creams for 1, 3, or 7 d treatments Only vaginal treatment in pregnancy Fluconazole 150 mg PO in single dose	No treatment if non-pregnant and asymptomatic, unless scheduled for pelvic surgery or procedure **Oral** Metronidazole 500 mg PO BID x 7 d* Oral treatment is best in pregnancy **Vaginal** Metronidazole 0.75% gel x 5 d once daily Clindamycin 2% 5 g intravaginally at bedtime for 7 d Probiotics (*Lactobacillus* sp.): oral or topical alone or as adjuvant	Treat even if asymptomatic Metronidazole 2 g PO single dose or metronidazole 500 mg BID x 7 d (alternative) Symptomatic pregnant women should be treated with metronidazole 2 g once
Other	Prophylaxis for recurrent infection includes boric acid, vaginal suppositories, luteal phase fluconazole Routine treatment of partner(s) not recommended (not sexually transmitted)	Associated with recurrent preterm labour, preterm birth, and postpartum endometritis Routine treatment of partner(s) not recommended (not sexually transmitted)	Treat partner(s) (sexually transmitted)

* Need to warn patients on metronidazole not to consume alcohol (disulfiram-like action)

Sexually Transmitted Infections

- see Family Medicine, FM46

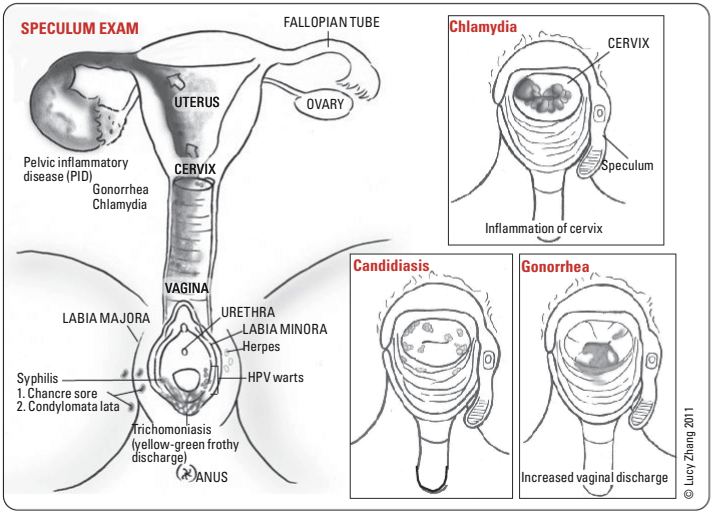

Figure 13. Speculum exam

CDC Notifiable Diseases
- Chancroid
- Chlamydia
- Gonorrhea
- Hepatitis A, B, C
- HIV
- Syphilis

Risk Factors for STIs
- History of previous STI
- Contact with infected person
- Sexually active individual <25 yr
- Multiple partners
- New partner in last 3 mo
- Lack of barrier protection use
- Social factors (homelessness, drug use)

TRICHOMONIASIS

- see *Infectious Vulvovaginitis, GY27*

CHLAMYDIA

Etiology

- *Chlamydia trachomatis*

Epidemiology

- most common bacterial STI in Canada
- often associated with *N. gonorrhoeae* (patients with chlamydia should also be tested for gonorrhea)

Clinical Features

- asymptomatic (80% of patients)
- muco-purulent endocervical discharge
- urethral syndrome: dysuria, frequency, pyuria, no bacteria on culture
- pelvic pain
- postcoital bleeding or intermenstrual bleeding (particularly if on OCP and prior history of good cycle control)
- symptomatic sexual partner

Investigations

- cervical culture or nucleic acid amplification test (can present in pharynx, rectum)
- obligate intracellular parasite: tissue culture is the definitive standard
- urine and self-administered vaginal tests now available, which are equally or more effective than cervical culture

STI Testing
- Vaginal swab
- Tests for bacterial vaginosis, trichomoniasis, *Candida*
- Cervical swab
- Tests for gonorrhea and chlamydia

Treatment

- doxycycline 100 mg PO BID for 7 d or azithromycin 1 g PO in a single dose
  - doxycycline is contraindicated in the 2nd and 3rd trimesters of pregnancy
- reportable disease to public health
- test and provide empiric treatment to all sexual partners of the index case within 60 d prior to symptom onset or date of specimen collection (if the index case is asymptomatic)
- test of cure is recommended 3 wk after completion of treatment when compliance to treatment is suboptimal, an alternative treatment regimen is used, persistent symptoms, or the person is prepubertal or pregnant

Test of cure for *C. trachomatis* and *N. gonorrhoeae* is not routinely indicated
Repeat testing if symptomatic, if compliance with treatment is uncertain, or if pregnant

Screening

- during pregnancy
- asymptomatic sexually active people under 25 yr
- neonates born to mothers with chlamydia
- any other people with risk factors for sexually transmitted and blood-borne infections

Complications
- PID: low-grade salpingitis and adhesions resulting in tubal obstruction
- infertility
- ectopic pregnancy
- chronic pelvic pain
- Fitz-Hugh-Curtis syndrome (liver capsule inflammation)
- reactive arthritis (male predominance, HLA-B27 associated), conjunctivitis, urethritis
- perinatal infection: conjunctivitis, pneumonia

GONORRHEA

Etiology
- *Neisseria gonorrhoeae*
- symptoms and risk factors same as chlamydia

Investigations
- Gram stain shows Gram-negative intracellular diplococci
- cervical, rectal, and throat culture (if clinically indicated)

Treatment
- single dose of ceftriaxone 250 mg IM plus azithromycin 1 g PO
  - if pregnant: above regimen or spectinomycin 2 g IM plus azithromycin 1 g PO (avoid quinolones)
  - also treat chlamydia, due to high rate of co-infection
- treat partners
  - reportable disease
  - screening as with chlamydia

HUMAN PAPILLOMAVIRUS

Etiology
- most common viral STI in Canada
- >200 subtypes, of which >30 are genital subtypes
- HPV types 6 and 11 are classically associated with anogenital warts/condylomata acuminata
- HPV types 16 and 18 are the most oncogenic (classically associated with cervical HSIL)
- types 16, 18, 31, 33, 35, 36, 45 (and others) associated with increased incidence of cervical and vulvar intraepithelial hyperplasia and carcinoma
  - HPV is readily transmissible between opposite and same-sex partners through receptive and penetrative vaginal, anal and oral sex, and non-penetrative sex (digital-vaginal sex and skin-to-skin contact)
  - infection with one HPV type does not appear to provide protection against infection with related HPV types

Clinical Features
- latent infection
  - no visible lesions, asymptomatic
  - only detected by DNA hybridization tests
- subclinical infection
  - visible lesion found during colposcopy or on Pap test
- clinical infection
  - visible wart-like lesion without magnification (check pharynx too)
  - hyperkeratotic, verrucous or flat, macular lesions
  - vulvar edema

Investigations
- cervical cytology by Pap test
  - koilocytosis: nuclear enlargement and atypia with perinuclear halo
- biopsy of lesions at colposcopy
- detection of HPV DNA subtype using nucleic acid probes (not routinely done but can be done in presence of abnormal Pap test to guide treatment)

Treatment
- anogenital warts
  - patient administered
    - podofilox 0.5% solution or gel BID x 3 d in a row (4 d off) then repeat x 4 wk
    - imiquimod (Aldara®) 5% cream 3x/wk nightly x 16 wk
    - sinecatechins 10% ointment 0.5 cm strand TID x up to 16 wk, daily dose ≤ 250 mg (need not be washed off)
  - provider administered
    - cryotherapy with liquid nitrogen: repeat q1-2 wk
    - podophyllin resin in tincture of benzoin: weekly
    - trichloroacetic acid (TCA) (80-90%) or bichloroacetic acid weekly x 4-6 wk; safe in pregnancy
    - surgical removal/laser
- intraepithelial lesions and cancers (See *Gynecological Oncology, GY42*)

Genital Warts During Pregnancy
- Condyloma tend to get larger in pregnancy and should be treated early (consider excision)
- Remove only if obstructing birth canal or risk of extensive bleeding
- Do not use imiquimod, podophyllin, or podofilox in pregnancy
- Baby at risk for juvenile respiratory papillomatosis, but condyloma dissection does not significantly reduce the risk

Human Rights in Health Equity: Cervical Cancer and HPV Vaccines
Am J Law Med 2009;35:365-387
- While cervical cancer rates have drastically fallen in developed countries due to effective prevention and treatment, socially disadvantaged women within these countries remain disproportionately more likely to develop and die of cervical cancer.
- In most developing countries cervical cancer rates have risen or remained unchanged.
- It must be recognized that cervical cancer disparities between race groups, urban and rural residence, and high and low socioeconomic status are attributed to disparate screening and vaccination coverage.
- Programs are implemented without sufficient attention to conditions that render screening less effective or inaccessible to disadvantaged social groups including: lack of information, undervaluing of preventive care, opportunistic delivery in limited healthcare settings, sexual health stigma, and related privacy concerns.

A 9-Valent HPV Vaccine Against Infection and Intraepithelial Neoplasia in Women
NEJM 2015;372:711-723
Purpose: To determine the efficacy and immunogenicity of the qHPV (types 6, 11, 16, 18) vs. 9vHPV (five additional types 31, 33, 45, 52, 58) vaccines.
Method: International randomized, double-blinded phase 2B-3 study of 9vHPV vaccine in 14215 women between ages of 16-26. Participants were randomized to the 9vHPV vaccine group or the qHPV vaccine group and each received a series of three IM injections (d 1, 2 mo, and 6 mo). Swabs of labial, vulvar, perineal, perianal, endocervical, and ectocervical tissue was obtained and used for HPV DNA testing/Pap smear.
Results: Rate of high-grade cervical, vulvar, or vaginal disease was 14.0 per 1000 person-yr in both vaccine groups. The rate of high-grade cervical, vulvar, or vaginal disease related to HPV-31, 33, 45, 52, and 58 was 0.1 per 1000 person-yr in the 9vHPV group and 1.6 per 1000 person-yr in the qHPV group (95% CI=80.9-99.8). Antibody responses to HPV-6, 11, 16, and 18 were not significantly different between the two vaccine groups although adverse events related to injection sites were more common in the 9vHPV group.
Conclusions: The 9vHPV vaccine was non-inferior to qHPV vaccine in preventing infection and disease related to HPV-6, 11, 16, and 18 and also covered additional oncogenic types HPV-31, 33, 45, 52, and 58 in a susceptible population.

Prevention
- vaccination: Gardasil®9, Gardasil®, Cervarix® (see *Table 28, GY49*)
- condoms may not fully protect (areas not covered, must be used every time throughout entire sexual act)

HERPES SIMPLEX VIRUS OF VULVA

Etiology
- 90% are HSV-2, 10% are HSV-1

Clinical Features
- may be asymptomatic
- initial symptoms: average incubation is 4 d after exposure (range 2-12 d)
- prodromal symptoms: tingling, burning, and pruritus
- multiple, painful, shallow ulcerations with small vesicles appear 7-10 d after initial infection (absent in many infected persons); lesions are infectious
- inguinal lymphadenopathy, malaise, and fever often with first infection
- dysuria and urinary retention if urethral mucosa affected
- recurrent infections: common but less severe, less frequent, and shorter in duration (usually only HSV-2)

Investigations
- viral culture preferred in patients with ulcer present; however, decreased sensitivity as lesions heal
- HSV DNA PCR
- cytologic smear (Tzanck smear) shows multinucleated giant cells, limited use due to low sensitivity and specificity
- type specific serologic tests for antibodies to HSV-1 and HSV-2 (not routinely available in Canada)

Treatment
- first episode: acyclovir 200 mg PO five times daily x 7-10 d, famciclovir 250 mg PO TID x 7-10 d, or valacyclovir 1 g PO BID x 7-10 d
- recurrent episode: acyclovir 400 mg PO TID x 5 d, famciclovir 125 mg PO BID x 5 d, or valacyclovir 1 g PO once daily x 5 d
- daily suppressive therapy
  - consider for >6 recurrences per yr or recurrence every 2 mo
  - acyclovir 400 mg PO BID, famciclovir 250 mg PO BID, valacyclovir 500 mg PO once daily, or valacyclovir 1 g PO once daily
- severe disease: IV acyclovir 5-10 mg/kg q8 h x 2-7 d or until clinical improvement observed followed by oral antiviral therapy to complete 10 d of total therapy
- education regarding transmission: avoid sexual contact from onset of prodrome until lesions have cleared, use barrier contraception

SYPHILIS

Etiology
- *Treponema pallidum*

Classifications
- primary syphilis
  - 3-4 wk after exposure (median incubation 21 d)
  - painless chancre on vulva, vagina, or cervix
  - painless inguinal lymphadenopathy
  - serological tests usually negative, local infection only
- secondary syphilis (can resolve spontaneously)
  - 2-6 mo after initial infection, in 25% of patients with untreated primary syphilis
  - nonspecific symptoms: malaise, anorexia, headache, and diffuse lymphadenopathy
  - generalized maculopapular rash: palms, soles, trunk, and limbs
  - condylomata lata: anogenital, broad-based, fleshy, grey lesions
  - serological tests usually positive
- latent syphilis
  - no clinical manifestations; detected by serology only
- tertiary syphilis
  - may involve any organ system
  - neurological: tabes dorsalis and general paresis
  - cardiovascular: aortic aneurysm and dilated aortic root
  - vulvar gumma: nodules that enlarge, ulcerate, and become necrotic (rare)
- congenital syphilis
  - may cause fetal anomalies, stillbirths, or neonatal death

Epidemiology of Genital Ulcers

HSV	70-80%
1° Syphilis	5%
Chancroid *(Haemophilus ducreyi)*	<1%

Investigations
- aspiration of ulcer serum or node
- dark field microscopy (most sensitive and specific diagnostic test for syphilis): look for spirochetes
- non-treponemal screening tests (VDRL, RPR); non-reactive after treatment, can be positive with other conditions
- specific anti-treponemal antibody tests (FTA-ABS, MHA-TP, TP-PA)
  - confirmatory tests; remain reactive for life (even after adequate treatment)

Treatment
- reportable disease, partners should be referred for treatment
- treatment of primary, secondary, latent syphilis of <1 yr duration
  - benzathine penicillin G 2.4 million units IM single dose
- treatment of latent syphilis of >1 yr duration
  - benzathine penicillin G 2.4 million units IM q1 wk x 3 wk
- treatment of neurosyphilis
  - IV aqueous penicillin G 3-4 million units q4 h x 10-14 d
- screening
  - high-risk groups (partner with syphilis, HIV-infected individuals, high risk sexual behaviour, history of incarceration)
  - in pregnancy (see Obstetrics, *Infections During Pregnancy, OB32*)

Complications
- if untreated, 25-40% will experience late complications

HIV
- see Infectious Diseases, ID27

Bartholin Gland Abscess

Etiology
- follows the infection of an obstructed Bartholin duct
- most commonly *E. coli*, polymicrobial, *S. aureus*, and Group B *Strep*

Clinical Features
- unilateral swelling and pain in inferior lateral opening of vagina
- sitting and walking may become difficult and/or painful

Treatment
- large mass >3 cm
  - 1st or 2nd episode: I&D under local anesthesia with placement of Word catheter (10 French latex catheter) for 2-3 wk
  - recurrence after two failed attempts with Word catheter: marsupialization in ER under sedation, or under GA
- small mass <3 cm
  - I&D with Word catheter, sitz baths, warm compresses
- antibiotics: reserved for patients with recurrence, high risk of complicated infection, culture-positive MRSA, systemic infection

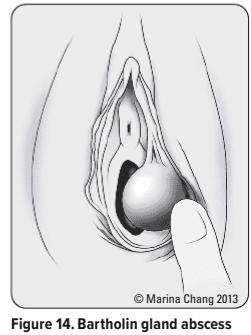

Figure 14. Bartholin gland abscess

Pelvic Inflammatory Disease

- infection of the upper genital tract (above the cervix) including endometrium, fallopian tubes, ovaries, pelvic peritoneum ± contiguous structures that primarily affects young, sexually active women

PID accounts for up to 20% of all gynecological hospital admissions

Etiology
- microbial etiology unknown in most cases, often considered a polymicrobial infection
- causative organisms (in order of frequency)
  - *C. trachomatis*
  - *N. gonorrhoeae*
    - gonorrhea and chlamydia often co-exist
  - *M. genitalium*
  - *E. coli* and colonic anaerobes found in rare cases of PID in postmenopausal women
  - very rare pathogens: *M. tuberculosis, H. influenzae, S. pneumoniae*, and the agents of actinomycosis

Risk Factors
- age 15-25 yr
- multiple partners, STI in partner
- previous PID
- IUD (extremely rare, occurs within first 3 wk after insertion)

PID Diagnosis

Minimum diagnostic criteria
- Cervical motion tenderness
- Uterine tenderness
- Adnexal tenderness

Additional diagnostic criteria
- Oral temperature >38.3°C
- Leukocytosis on saline microscopy of vaginal secretions/wet mount
- Elevated ESR or CRP
- Laboratory documentation of cervical infection with *N. gonorrhoeae* or *C. trachomatis*

Definitive diagnostic criteria
- Endometrial biopsy with histopathologic evidence of endometritis
- Transvaginal sonography or MRI showing thickened fluid-filled tubes, free fluid or tubo-ovarian complex
- Gold standard: laparoscopy demonstrating abnormalities consistent with PID

Clinical Features
- wide spectrum of clinical presentation: time course typically acute although many patients will have subclinical PID that does not prompt a patient to present for medical care but severe enough to cause significant sequelae (fertility issues)
- clinical diagnosis of PID: fever >38.3°C, lower abdominal pain and tenderness, and abnormal discharge (cervical or vaginal)
- uncommon: N/V, dysuria, and AUB
- chronic disease (often due to chlamydia)
  - constant pelvic pain
  - dyspareunia
  - palpable mass
  - very difficult to treat, may require surgery

Investigations
- blood work
  - β-hCG (must rule out ectopic pregnancy), CBC, blood cultures if suspect septicemia
- urine routine and microscopy (R&M)
- speculum exam, bimanual exam
  - vaginal swab for Gram stain, C&S
  - nucleic acid amplification tests (NAAT) for *N. gonorrhoeae, C. trachomatis, M. genitalium*
  - HIV testing and serologic testing for syphilis
- ultrasound
  - may be normal
  - free fluid in cul-de-sac
  - pelvic or tubo-ovarian abscess
  - hydrosalpinx (dilated fallopian tube)
- laparoscopy
  - only done in patients that have failed outpatient treatment, symptoms not improving after 72 h of inpatient treatment, or unclear diagnosis
  - surgery has high specificity but low sensitivity

Treatment
- must treat with polymicrobial coverage
- percutaneous drainage of abscess under U/S guidance
- laparoscopic drainage when no response to treatment, surgical (salpingectomy, TAH/BSO) if failure
- consider removing IUD after a minimum of 24 h of treatment
- reportable disease, treat partners
- consider re-testing for *C. trachomatis* and *N. gonorrhoeae* 4-6 wk after treatment if documented infection

Table 16. Inpatient and Outpatient Management Options for Pelvic Inflammatory Disease

	Inpatient	Outpatient
Indications	Moderate to severe illness Atypical infection Adnexal mass, tubo-ovarian mass, or pelvic abscess Failed or cannot tolerate oral therapy Immunocompromised Pregnant Adolescent (first episode) Surgical emergency cannot be excluded (e.g. ovarian torsion) PID is secondary to instrumentation	Typical findings Mild to moderate illness Oral antibiotics tolerated Compliance ensured Follow up within 48-72 h (to ensure symptoms not worsening)
Antibiotic Regimen	Cefoxitin 2 g IV q6 h + doxycycline 100 mg PO/IV q12 h or Clindamycin 900 mg IV q8 h + gentamycin 2 mg/kg IV/IM loading dose then gentamicin/tobramicin 1.5 mg/kg q8 h maintenance dose Continue IV antibiotics for 24 h after symptoms have improved then doxycycline 100 mg PO BID to complete 14 d (add metronidazole 500 mg PO BID x 14 d in patients with tubo-ovarian abscess)	1st line: ceftriaxone 500 mg IM x 1 dose + doxycycline 100 mg PO BID x 14 d or cefoxitin 2 g IM x 1 dose + probenecid 1 g PO + doxycycline 100 mg PO BID ± metronidazole 500 mg PO BID x 14 d 2nd line: ofloxacin 400 mg PO BID x 14 d or levofloxacin 500 mg PO once daily x 14 d ± metronidazole 500 mg PO BID x 14 d

Complications of Untreated Pelvic Inflammatory Disease

- chronic pelvic pain
- persistent hydrosalpinx
- abscess, peritonitis
- adhesion formation
- ectopic pregnancy
- infertility
  - 1 episode of PID: 13% infertility
  - 2 episodes of PID: 36% infertility
- bacteremia
- septic arthritis, endocarditis

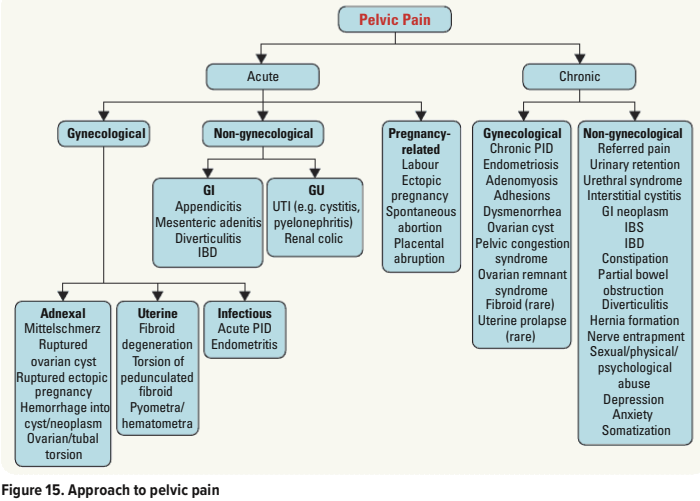

Figure 15. Approach to pelvic pain

Toxic Shock Syndrome (TSS)

- see Infectious Diseases, ID22
- Staphylococcal toxic shock syndrome (TSS) is a clinical illness characterized by rapid onset of fever, rash, hypotension, and multiorgan system involvement

Toxic Shock Syndrome
Multiple organ system failure due to *S. aureus* exotoxin (rare condition)

Risk Factors

- menstrual TSS
  - significantly decreased as a result of the withdrawal of highly-absorbent tampons and polyacrylate rayon-containing products from the market; however, tampon use remains a risk factor for TSS (high absorbency, tampons used continuously for more days of their cycle, and keeping a single tampon in place for a longer period of time)

- non-menstrual TSS (gynecologic)
  - diaphragm, cervical cap, or sponge use (prolonged use, i.e. >24 h)
  - surgical and postpartum wound infections, mastitis, sinusitis, osteomyelitis, arthritis, burns, cutaneous lesions, etc.

Clinical Features
- sudden high fever/chills
- sore throat, headache, and diarrhea
- macular erythroderma followed by desquamation 1-2 wk later
- signs of multisystem organ failure
- refractory hypotension

Treatment
- treatment of shock
- remove potential sources of infection (foreign objects)
- surgical debridement (if warranted)
- adequate hydration
- empiric antibiotic therapy with vancomycin (load 20-35 mg/kg and maintenance 15-20 mg/kg q8-12 h) + clindamycin 900 mg IV q8 h + piperacillin-tazobactam 4.5 g IV q6 h
- continue combination therapy until patient is hemodynamically stable for at least 48-72 h

Surgical Infections

Postoperative Infections in Gynecological Surgery
- pelvic cellulitis
  - common post hysterectomy, affects vaginal vault
  - erythema, induration, tenderness, and discharge involving vaginal cuff
  - if fever and leukocytosis, treat with broad-spectrum ABx (i.e. clindamycin and gentamicin)
  - drain if excessive purulence or large mass
  - can result in intra-abdominal and pelvic abscess
- see General and Thoracic Surgery, *Postoperative Fever, GS8*

Sexual Abuse

- see Emergency Medicine, ER27 and Family Medicine, FM46

Sexuality and Sexual Dysfunction

SEXUAL RESPONSE
1. desire: energy that allows an individual to initiate or respond to sexual stimulation (libido)
2. arousal: physical and emotional stimulation leading to breast and genital vasodilation and clitoral engorgement (excitement)
3. orgasm: physical and emotional stimulation is maximized, allowing the individual to relinquish their sense of control
4. resolution: most of the congestion and tension resolves within seconds, complete resolution may take up to 60 min

Note: this framework cannot be applied consistently to a patient's sexual response. For many patients, the phases may vary in sequence, overlap, repeat, or be absent during some or all sexual encounters

SEXUAL DYSFUNCTION

Classification
- lack of desire (most common)
- lack of arousal
- anorgasmia
  - primary anorgasmia: never achieved orgasm under any circumstances
  - secondary anorgasmia: was able to achieve orgasms before but unable to achieve orgasms presently
- dyspareunia: painful intercourse, can be superficial or deep

Etiology
- biological:
  - gynecological (e.g. pregnancy, childbirth, menopausal atrophy, endometriosis, prolapse, urinary incontinence)
  - urological (e.g. recurrent UTI, chronic renal failure)
  - vascular (e.g. peripheral vascular disease, CAD)
  - neurological dysfunction (e.g. nerve entrapment syndrome, spinal cord injury, multiple sclerosis, Parkinson's)

  - musculoskeletal (e.g. arthritis, mechanical back pain)
  - systemic health disorders (e.g. DM, thyroid disorders)
  - medication side effects (e.g. β-blockers, benzodiazepines, SSRIs, antipsychotics, oral contraceptives)
  - behavioural or lifestyle (e.g. smoking, alcohol consumption, opioids, obesity)
- psychological:
  - early events: history of sexual violence, unpleasant early sexual experiences, or growing up in a family or society that communicates no information or negative messages about female sexuality
  - current events: depression, anxiety, psychosis, fatigue, stress, or other mental health disorders
- relationship:
  - abuse
  - relationship distress
  - failure to engage in effective sexual stimulation

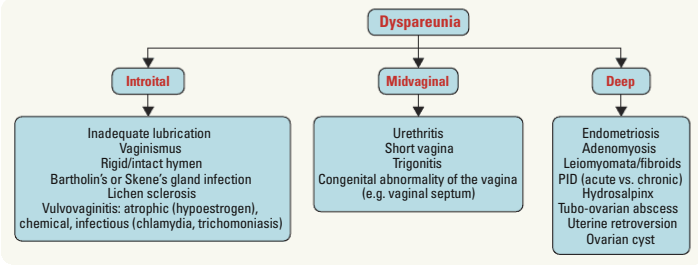

Figure 16. Approach to dyspareunia

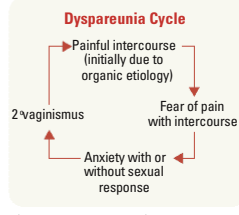


Dyspareunia Cycle
Painful intercourse (initially due to organic etiology)
Fear of pain with intercourse
Anxiety with or without sexual response
2° vaginismus

Figure 17. Dyspareunia cycle

Treatment

- general:
  - assess patient goals and construct a safety plan as needed
  - counselling
  - lifestyle changes
  - improve body image
- lack of desire:
  - biological: rule out other conditions/medication side effects; consider sildenafil for SSRI side effects; consider androgens (testosterone, DHEA), estrogens, tibolone in postmenopausal women; consider serotonergic and dopaminergic agents: flibanserin, bupropion, buspirone; consider bremelanotide
  - psychological: rule out/treat depression, other mental health issues
  - relationship: assess couple interaction and partner sexual function; treat partner and relationship conflict
- concerns with arousal/lubrication:
  - biological: non-hormonal, water-based lubricants; consider estrogen (topical cream, tablet, or ring) or coconut oil
  - psychological: address sexual anxieties
  - relationship: education regarding slowing of sexual response with aging
- anorgasmia:
  - biological: augment stimulation ± vibrator; consider androgens
  - psychological: sex education, anxiety reduction, and use of erotica
  - relationship: stimulation needs and helping patient teach partner what they need
- sexual pain disorders:
  - biological: rule out other conditions; topical estrogen if atrophy; consider nerve modulators (amitriptyline, gabapentin, or pregabalin); pelvic floor physiotherapy
  - psychological: sex therapy if vaginismus
  - relationship: rule out abuse (with patient alone)

Menopause

• see Family Medicine, FM43

Definitions

• lack of menses for 1 yr
• timing of menopause
  ▪ physiological; average age 51 yr (follicular atresia)
  ▪ premature ovarian insufficiency; before age 40 (autoimmune disorder, infection, Turner's syndrome)
  ▪ iatrogenic (surgical/radiation/chemotherapy)

Clinical Features

• associated with estrogen deficiency
  ▪ vasomotor instability (tends to dissipate with time)
    ◆ hot flushes/flashes, night sweats, sleep disturbances, formication, nausea, and palpitations
  ▪ urogenital atrophy involving vagina, urethra, and bladder (genitourinary syndrome of menopause (GUSM))
    ◆ dyspareunia, pruritus, vaginal dryness, bleeding, post-coital bleeding, urinary frequency, urgency, and incontinence
    ◆ inspection may reveal: thinning of tissues, erythema, petechiae, abrasions, and dryness on speculum exam
  ▪ skeletal
    ◆ osteoporosis, joint and muscle pain, and back pain
  ▪ skin and soft tissue
    ◆ decreased breast size, and skin thinning/loss of elasticity
  ▪ psychological
    ◆ increased anxiety, depression, irritability, fatigue, decreased libido, and memory loss

Investigations

• for women with irregular cycles and menopausal symptoms:
  ▪ >45 yr: no testing necessary
  ▪ 40-45 yr: β-hCG, prolactin, TSH
  ▪ <40 yr: β-hCG, FSH, prolactin, TSH
• increased levels of FSH (>35 IU/L) on day 3 of cycle (if still cycling) and LH (FSH>LH)
• FSH level not always predictive due to monthly variation; use absence of menses for 1 yr to diagnose
• decreased levels of estradiol (later)

Treatment

• goal is for individual symptom management

Table 17. Treatment of Menopause

Vasomotor Instability	Vaginal Atrophy	Urogenital Health	Osteoporosis	Decreased Libido	CVD*	Mood and Memory
Menopause hormonal therapy (MHT) as first line, SSRI, venlafaxine, gabapentin, propanolol, clonidine, acupuncture, behavioural modifications	Local estrogen: cream (Premarin® or Estragyn Vaginal Cream®), vaginal suppository (VagiFem®), ring (Estring®), lubricants (Replens®), intravaginal laser	Lifestyle changes (weight loss, bladder training), pelvic floor exercises, local estrogen replacement, surgery	Calcium 1000-1500 mg once daily, vitamin D 800-1000 IU, weight-bearing exercise, smoking cessation, bisphosphonates (e.g. alendronate), SERMs (e.g. raloxifene (Evista®)), HRT (second-line treatment)	Vaginal lubricants, counselling, androgen-replacement testosterone cream or the oral form (Andriol®)	Manage CVD risk factors	Anti-depressants (first line), MHT (augments effect), CBT

*CVD (cardiovascular disease)

Menopause
Occurrence of last spontaneous menstrual period, resulting from loss of ovarian function (loss of oocyte response to gonadotropins)

"Being in menopause"
Lack of menses for 1 yr

Perimenopause
Period of time surrounding menopause (2-8 yr preceding + 1 yr after last menses) characterized by fluctuating hormone levels, irregular menstrual cycles, and symptom onset

Menopause Pathophysiology

Degenerating theca cells fail to react to endogenous gonadotropins (FSH, LH)
↓
Less estrogen is produced
↓
Decreased negative feedback on hypothalamic-pituitary-adrenal axis
↓
Increased FSH and LH
↓
Stromal cells continue to produce androgens as a result of increased LH stimulation

Figure 18. Menopause pathophysiology

85% of women experience hot flashes
20-30% seek medical attention
10% are unable to work

Menopause Hormone Therapy

- see Family Medicine, FM43

Treatment Guidelines

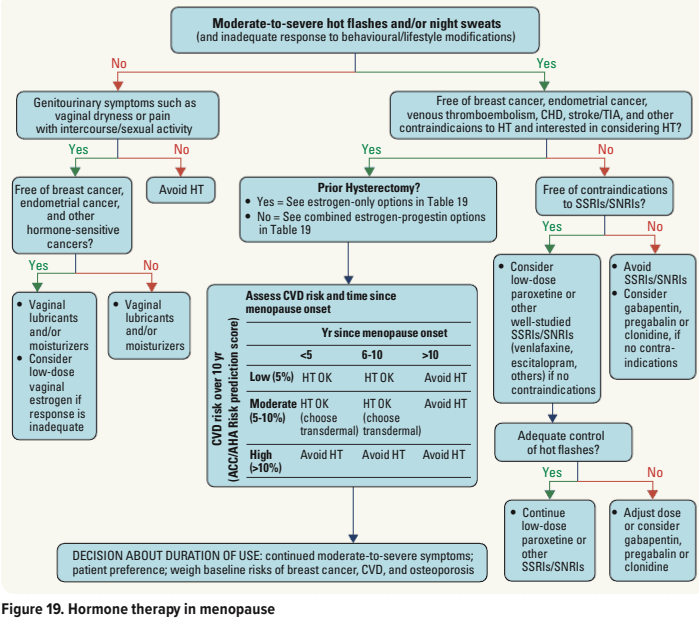
- primary indication is treatment of menopausal symptoms (vasomotor instability)
  - should not be prescribed if the only objective is the prevention of chronic disease
- before starting, review the benefits and risks (see *Table 18*) and contraindications with the patient
- use the lowest effective dose; patients with standard dose should be advised to lower dose after a few years
- patients receiving MHT must be evaluated annually
- decisions around duration of treatment should be individualized, but recommended to avoid treatment >5 yr with combination estrogen and progesterone treatment due to the duration-dependent risk of breast cancer
  - tapering and abruptly discontinuing MHT have similar impact on symptom recurrence, but for patients with a history of severe baseline vasomotor symptom, gradual tapering is probably preferable

Table 18. MHT Benefits vs. Risks

Benefits	Risks
Reduction of vasomotor symptoms Reduction of sleep problems Reduction of mood or anxiety problems Reduction of aches and pains Osteoporosis prevention and treatment Reversal of vulvar and vaginal atrophy (local estrogen therapy recommended if such atrophy is the only indication for therapy)	Thromboembolic events Stroke Breast cancer (increased risk after 4-5 yr with estrogen-progesterone regimens, no increased risk for at least 8 yr with estrogen-alone and no uterus regimens) Coronary heart disease (for women age >60 and those who are >10 yr after menopause) Endometrial hyperplasia and cancer (with estrogen-only regimens and uterus *in situ*)

MHT Components

- estrogen
  - oral or transdermal (e.g. patch, gel)
  - transdermal preferred for patients overall, especially with hypertriglyceridemia or impaired hepatic function, smokers, and patients low-dose (preferred dose: Premarin® 0.3 mg/Estradot® patch 25 µg, can increase if necessary)
- progestin
  - given in combination with estrogen for patients with an intact uterus to prevent development of endometrial hyperplasia/cancer



Moderate-to-severe hot flashes and/or night sweats
(and inadequate response to behavioural/lifestyle modifications)
No
Yes
Genitourinary symptoms such as vaginal dryness or pain with intercourse/sexual activity
Free of breast cancer, endometrial cancer, venous thromboembolism, CHD, stroke/TIA, and other contraindicaions to HT and interested in considering HT?
Yes
No
Yes
No
Free of breast cancer, endometrial cancer, and other hormone-sensitive cancers?
Avoid HT
Prior Hysterectomy?
• Yes = See estrogen-only options in Table 19
• No = See combined estrogen-progestin options in Table 19
Free of contraindications to SSRIs/SNRIs?
Yes
No
Yes
No
• Vaginal lubricants and/or moisturizers
• Consider low-dose vaginal estrogen if response is inadequate
• Vaginal lubricants and/or moisturizers
Assess CVD risk and time since menopause onset
CVD risk over 10 yr (ACC/AHA Risk prediction score)
Yr since menopause onset
<5
6-10
>10
Low (5%) HT OK HT OK Avoid HT
Moderate (5-10%) HT OK (choose transdermal) HT OK (choose transdermal) Avoid HT
High (>10%) Avoid HT Avoid HT Avoid HT
• Consider low-dose paroxetine or other well-studied SSRIs/SNRIs (venlafaxine, escitalopram, others) if no contraindications
• Avoid SSRIs/SNRIs
• Consider gabapentin, pregabalin or clonidine, if no contra-indications
Adequate control of hot flashes?
Yes
No
• Continue low-dose paroxetine or other SSRIs/SNRIs
• Adjust dose or consider gabapentin, pregabalin or clonidine
DECISION ABOUT DURATION OF USE: continued moderate-to-severe symptoms; patient preference; weigh baseline risks of breast cancer, CVD, and osteoporosis

Figure 19. Hormone therapy in menopause

Long-Term Hormone Therapy for Perimenopausal and Postmenopausal Women
Cochrane DB Syst Rev 2017;1:CD004143
Purpose: To determine the effect of long-term HT (hormone therapy) on mortality, cardiovascular outcomes, cancer, gallbladder disease, fractures, cognition, and quality of life (QOL) in perimenopausal and postmenopausal women, during HT use, and after cessation of HT.
Results: 22 studies with 43637 women included. Most studies included postmenopausal American women with at least some degree of comorbidity, with a mean participant age over 60 yr. Combined continuous HT: increased risk of coronary event after 1 yr (from 2/1000 to 3-7/1000), venous thromboembolism after 1 yr (2/1000 to 4-11/1000), stroke after 3 yr (6/1000 to 6-12/1000), breast cancer after 5.6 yr (19/1000 to 20-30/1000), gallbladder disease after 5.6 yr (27/1000 to 38-60/1000), and death from lung cancer after 5.6 yr use plus 2.4 yr additional follow up (5/1000 to 6-13/1000). Estrogen only HT: increased risk of venous thromboembolism after 1-2 yr use (2/1000 to 2-10/1000; after 7 yr, 16/1000 to 16-28/1000), stroke after 7 yr (24/1000 to 25-40/1000), and gallbladder disease after 7 yr use (27/1000 to 38-60/1000) but reduced the risk of breast cancer after 7yr (25/1000 to 15-25/1000 and clinical fracture after 7yr (141/1000 to 92-113/1000). Women >65 yr of age taking combined HT had shown an increase in the incidence of dementia after 4 yr use (9/1000 to 11-30/1000). For women with cardiovascular disease, use of combined continuous HT significantly increased the risk of venous thromboembolism at 1 yr (3/1000 to 3-29/1000).
Conclusions: HT may be contraindicated for some women with increased risk of cardiovascular disease, thromboembolic disease, and certain cancers such as breast cancer in women with a uterus. HT is not indicated for primary or secondary prevention of cardiovascular disease, dementia, or deterioration of cognitive function.

Osteoporosis is the single most important health hazard associated with menopause

Cardiovascular disease is the leading cause of death post-menopause

Increased risk of breast cancer (RR 1.3) is associated with estrogen+progesterone HRT, but not with estrogen-only HRT

All women taking HRT should have periodic surveillance and counselling regarding its benefits and risks

Table 19. Examples of MHT Regimens

MHT Regimen	Trade Names	Standard Doses
Estrogen-only – oral	Estrace®	17 β-estradiol 0.5-1 mg tablet daily
	Premarin®	CE 0.3-0.625 mg tablet daily
	Estragyn®	Esterified estrogens 0.3-0.625 mg cyclic
Estrogen-only – transdermal	Patches:	
	Estradot®, Sandoz Estradiol Derm®, Oesclim®, Climara®	17 β-estradiol 25-100 µg 1-2x/wk
	Gel:	
	Estrogel®	1-2 metered doses/actuation daily
	Divigel®	0.25-1 mg packets daily
Estrogen-only – vaginal	Cream:	
	Premarin®	CE 0.625 mg/g
	Estragyn®	Estrone 1 mg/g
	Inserts: Vagifem®	17 β-estradiol 10 µg
	Ring: Estring®	17 β-estradiol 2 mg
Combined E-P – oral	Activelle®	1 mg 17 β-estradiol/0.5 mg NEA
	Angeliq®	1 mg 17 β-estradiol/1 mg drospirenone
Combined E-P – transdermal	Patch: Estalis® (2 doses available)	17 β-estradiol/NEA: 50/140 mµg continuous 2x/wk 50/140 mµg or 50/250 mµg cyclic 2x/wk

CE = conjugated estrogen; E-P = estrogen-progestin; NEA = norethindrone acetate
Current common practice includes using the Mirena® IUD as the progesterone component (levonorgestrel 52 mg over 5 yr, approximately 20 µg/d)

Side Effects of MHT

- estrogen
  - breast tenderness
  - nausea
  - headache
  - bloating
- progestins
  - mood alterations
  - breast tenderness
  - bloating
  - sedation (micronized progesterone)

Contraindications to MHT

- absolute
  - acute liver disease
  - undiagnosed vaginal bleeding
  - history of breast cancer
  - known or suspected uterine cancer/breast cancer
  - acute vascular thrombosis, or history of severe thrombophlebitis or thromboembolic disease
  - cardiovascular disease
- relative
  - pre-existing uncontrolled HTN
  - uterine fibroids and endometriosis
  - familial hyperlipidemias
  - migraine headaches
  - family history of estrogen-dependent cancer
  - chronic thrombophlebitis
  - DM (with vascular disease)
  - gallbladder disease, hypertriglyceridemia, and impaired liver function (consider transdermal estrogen)
  - fibrocystic disease of the breasts

Menopausal Hormone Therapy and Health Outcomes During the Intervention and Extended Poststopping Phases of the Women's Health Initiative Randomized Trials
JAMA 2013;310:1353-1368
Purpose: To report comprehensive findings from the 2 Women's Health Initiative (WHI) hormone therapy trials with extended post-intervention follow-up.
Methods: A total of 27347 postmenopausal women ages 50-79 were enrolled at 40 US centers. In the CEE+MPA trial, 16608 women, with intact uterus, received either continuous combined HRT (CEE 0.625 mg + MPA 2.5 mg once daily) or placebo. In the CEE-only trial, 10739 women, with prior hysterectomy, received either CEE 0.625 mg once daily or placebo.
Results: Results all reported as difference between treatment and placebo in cases per 100000 person-yr, stratified by age.

	CEE + MPA trial		CEE alone trial	
CHD	50-59	5	50-59	-11
	60-69	0	60-69	-3
	70-79	19	70-79	7
Invasive breast cancer	50-59	6	50-59	-5
	60-69	8	60-69	-10
	70-79	15	70-79	-5
Stroke	50-59	5	50-59	-1
	60-69	11	60-69	18
	70-79	13	70-79	17
PE	50-59	6	50-59	3
	60-69	8	60-69	7
	70-79	18	70-79	-2
Colorectal cancer	50-59	-1	50-59	-3
	60-69	-8	60-69	-2
	70-79	-11	70-79	19

	60-69	-4	60-69	-6
	70-79	-14	70-79	-21

Absolute Contraindications to MHT

ABCD
Acute liver disease
Undiagnosed vaginal Bleeding
Cancer (breast/uterine), Cardiovascular disease
DVT (thromboembolic disease)

Urogynecology

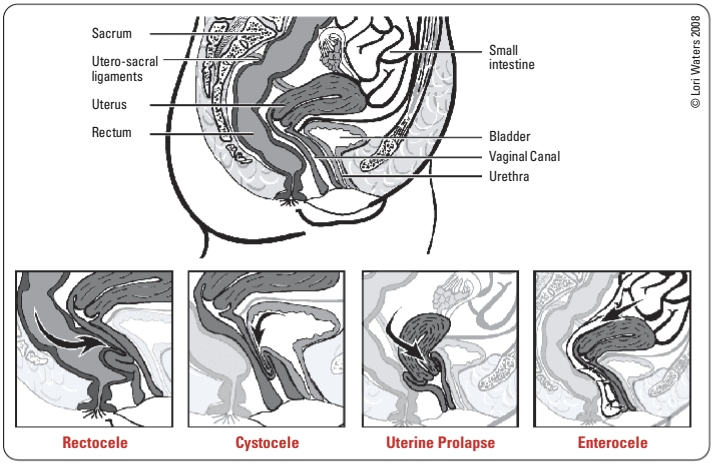

Figure 20. Pelvic anatomy

Pelvic Organ Prolapse

Etiology

- related to:
  - vaginal childbirth
  - aging
  - decreased estrogen (post-menopause)
  - increased intra-abdominal pressure (obesity, chronic cough, constipation, ascites, heavy lifting)
  - ethnicity (greater incidence in White women > Asian or African women)
  - connective tissue disorders

Pelvic Organ Prolapse
A weakening in the structures of the pelvic floor resulting in descent of one or more of the pelvic structures (bladder/rectum/small intestine/uterus) into the vagina

Diagnosis

- medical history
  - assess symptoms specific to prolapse: pressure, bulge
  - assess urinary, defecatory, and sexual concerns, which are often associated with pelvic organ prolapse
- physical exam (each component with patient relaxed and then while straining)
  - inspection in the dorsal lithotomy position
  - evaluate for apical prolapse with a bivalve speculum exam, then evaluate for anterior and posterior prolapse with the posterior blade of the bivalve speculum
  - use the POP-Q staging system to quantify stage of prolapse
  - evaluate for any coexisting pelvic abnormalities with a bimanual exam
  - test the strength of pelvic floor muscles with voluntary Kegel contractions
- ancillary studies
  - if continent with apical prolapse, consider clinical or urodynamic testing with and without reduction of prolapse to investigate for occult stress urinary incontinence
  - if voiding symptoms, consider post-void residual volume to evaluate urinary retention
  - if urgency or other UTI symptoms, consider urine microscopy and culture to test for UTI

POP-Q Staging of Pelvic Organ Prolapse
0 = no prolapse
1 = most distal portion of prolapse >1 cm above level of hymen
2 = most distal portion of prolapse is between 1 cm above or below the hymen
3 = most distal portion of prolapse >1 cm below level of hymen but no further than 2 cm less than the total vaginal length
4 = complete procidentia (uterus present with complete herniation of anterior, posterior, and apical compartments) or vault eversion (no uterus present with complete eversion of the anterior, posterior, and apical compartments), most distal prolapse protrudes 2 cm of total vaginal length

GENERAL CONSERVATIVE TREATMENT

- weight loss
- pelvic floor muscle training (e.g. Kegel exercises, pelvic physiotherapy)
- local vaginal estrogen therapy
- vaginal pessary (intravaginal devices that are either supportive or space-occupying)

The primary clinical features of pelvic organ prolapse are vaginal bulge and pressure

Table 20. Types and Management of Pelvic Organ Prolapse

Type	Clinical Features	Treatment
Anterior Vaginal Wall Prolapse (previously "cystocele") (protrusion of bladder into the anterior vaginal wall)	Frequency, urgency, nocturia Stress incontinence Incomplete bladder emptying ± associated increased incidence of UTIs (may lead to renal impairment)	General conservative treatment (see above) Anterior colporrhaphy ("anterior repair") Consider additional/alternative surgical procedure if documented urinary stress incontinence Can consider pessary
Posterior Vaginal Wall Prolapse (previously "rectocele") (protrusion of rectum into posterior vaginal wall)	Straining/digitation to evacuate stool Constipation	General conservative treatment (see above) Also laxatives and stool softeners Posterior colporrhaphy ("posterior repair"), plication of endopelvic fascia and perineal muscles approximated in midline to support rectum and perineum (can result in dyspareunia)
Uterine Prolapse (protrusion of cervix and uterus into vagina)	A type of apical prolapse Groin/back pain (stretching of uterosacral ligaments) Feeling of heaviness/pressure in the pelvis Worse with standing, lifting Worse at the end of the day Relieved by lying down Ulceration/bleeding (particularly if hypoestrogenic) ± urinary incontinence	General conservative treatment (see above) Vaginal hysterectomy ± surgical prevention of vault prolapse Consider additional surgical procedures if urinary incontinence, cystocele, rectocele, and/or enterocele are present Can consider pessary
Vault Prolapse (previously "enterocele", protrusion of apex of vaginal vault into vagina, post-hysterectomy, often containing small bowel)	A type of apical prolapse Same as uterine prolapse	General conservative treatment (see above) Sacralcolpopexy (vaginal vault suspension), sacrospinous fixation, or uterosacral ligament suspension

Surgery: native tissue repair vs. mesh reconstruction (usually reserved for severe, recurrent prolapse)

The only **true** hernia of the pelvis is an ENTEROCELE because peritoneum herniates with the small bowel

Kegel Exercises
Regular contraction and relaxation to strengthen pelvic floor muscles

Reverse Kegel Exercises
1 s contraction then 5 s of relaxation

Urinary Incontinence

- see Urology, U6

STRESS INCONTINENCE

Definition
- involuntary loss of urine with increased intra-abdominal pressure (cough, laugh, sneeze, walk, run)
- affects 4-35% of all women

Risk Factors for Stress Incontinence in Women
- increased age
- obesity
- pregnancy/vaginal delivery
- hypoestrogenic state (post-menopause)
- smoking/chronic cough
- neurological
- genetics
- high impact exercise

Diagnosis
- history
  - onset, frequency, severity, and pattern of urinary incontinence
  - frequency, dysuria, urgency, and nocturia
  - pads used per 24 h
  - obstructive urinary symptoms (incomplete voiding, hesitancy, straining, post-void dribbling, and recurrent UTI)
  - pelvic organ prolapse symptoms
  - neurological conditions/symptoms
  - obstetric history, and current menopause/hormone therapy status
  - medications (sedatives, diuretics, anticholinergic medications, and OTCs)
  - lifestyle risk factors (caffeine, smoking, weight, exercise, and occupation)
  - urinary diary
- physical exam
  - height, weight, and BMI
  - abdominal exam: scars, abdominal mass, and presence of a full bladder
  - neurological exam: S2-S4 sacral nerves (motor, sensory, and reflexes)
  - elderly: mini mental status exam, and observe mobility
  - pelvic exam: inspect vulva and urogenital epithelium, assess for signs of pelvic organ prolapse, and digital rectal exam to assess for anal sphincter tone and perineal sensation
  - standing stress test

- studies
  - urinalysis: hematuria, pyuria, glucosuria, proteinuria
    - hematuria/irritative voiding symptoms: cytology
    - pyuria/bacteria: urine culture
  - post-void residual
    - normal: ≤1/3 total volume
    - abnormal: >1/3 total volume (poor bladder contractility or bladder outlet obstruction)
  - urodynamic testing

Treatment
- for conservative management, see *Pelvic Organ Prolapse, GY39*
- procedures: vaginal laser, urethral bulking
- surgical
  - midurethral sling (TVT, TOT)
  - urethropexy (Burch procedure)
  - pubovaginal sling
  - urethral bulking

OVERACTIVE BLADDER

Definition
- symptom syndrome defined as "urgency, with or without urge urinary incontinence (UUI), usually with frequency and nocturia"
- 16% of all patients
- UUI: involuntary leakage with or immediately preceded by a strong desire to void
  - involuntary bladder contraction that overcomes the urethral sphincter mechanism OR
  - poor bladder compliance

Etiology
- idiopathic: congenital and aging
- medical: CHF, DM, and diuretics
- neurogenic: multiple sclerosis, Parkinson's, CVD, dementia, and spinal cord injury
- bladder outlet obstruction: previous bladder neck surgery and pelvic organ prolapse
- gynecologic: UTI, pregnancy, pelvic mass, and urethral diverticulum
- psychosomatic: habits, anxiety, and high fluid consumption

Diagnosis
- see *Stress Incontinence, GY40* for diagnosis

Treatment
- behaviour modification (reduce bladder irritants (caffeine, smoking, alcohol, acidic, spicy); adequate water intake; regular voiding schedule)
- bladder training with pelvic physiotherapist
- medications
  - anticholinergics
    - oxybutynin (oral: Ditropan®; patch: Oxytrol®; transdermal gel: Gelnique®)
    - tolterodine (Detrol®)
    - fesoterodine (Toviaz®)
    - solifenacin (Vesicare®)
    - trospium (Trosec®)
    - darifenacin (Enablex®)
  - β-adrenergic agonist: mirabegron (Myrbetriq®)
- procedures: sacral neuromodulation, detrusor botox injection

Gynecological Oncology

Pelvic Mass

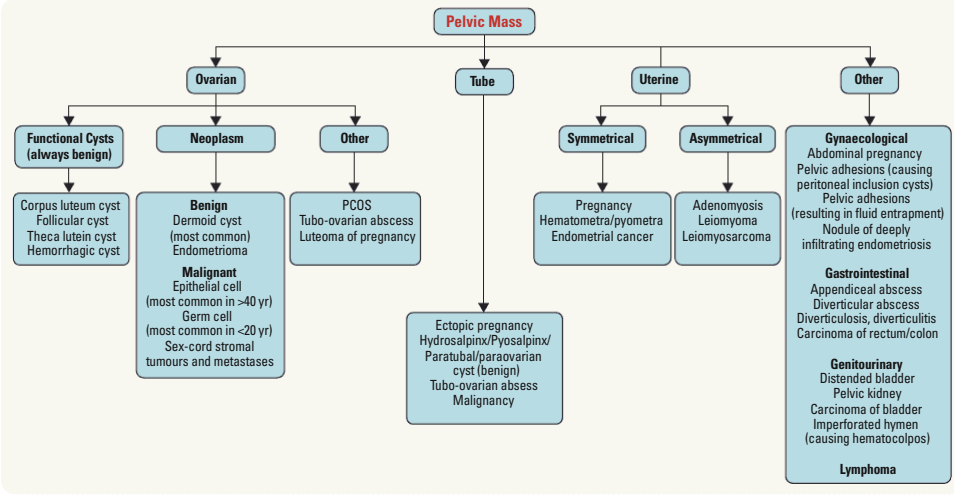

Figure 21. Differential diagnosis of pelvic mass

Uterus

ENDOMETRIAL CARCINOMA

Epidemiology

- most common gynaecological malignancy in North America (40%); 4th most common cancer in women
- 2-3% of patients with a uterus develop endometrial carcinoma during their lifetime
- mean age is 60 yr
- majority are diagnosed in early stage due to detection of symptoms
- 85-90% 5 yr survival for stage I disease
- 70-80% 5 yr survival for all stages

Table 21. Features of Type I and Type II Endometrial Cancer

	Type I	Type II
Description	Estrogen-related (i.e. excess/unopposed estrogen): Endometrioid Includes well-differentiated (grade 1 and 2) endometrioid adenocarcinoma 80% of cases	Non-estrogen related: Non-endometrioid Includes serous, clear cell, grade 4 endometrioid and undifferentiated carcinomas, carcinosarcoma 20% of cases, poorer prognosis
Risk Factors (Increasing age and family history are risk factors for both types)	PCOS Diabetes mellitus Unbalanced HRT (balanced HRT is protective) Nulliparity or history of infertility related to anovulation Late menopause (>55 yr), early menarche Estrogen-producing ovarian tumours (e.g. granulosa cell tumours) HNPCC*/Lynch II syndrome Tamoxifen Prior pelvic radiation	Parous people More likely in Black patients Associated with p53 mutation, HER2 overexpression
Clinical Features	Postmenopausal bleeding AUB in premenopausal patients (menorrhagia, intermenstrual bleeding)	AUB

*HNPCC = Hereditary non-polyposis colorectal cancer

Incidence of Malignant Gynecological Lesions in North America
endometrium > ovary > cervix > vulva > vagina > fallopian tube

Risk Factors for Endometrial Cancer

COLD NUT
Cancer (ovarian, breast, colon)
Obesity
Late menopause
Diabetes mellitus
Nulliparity
Unopposed estrogen: PCOS, anovulation, HRT
Tamoxifen (chronic use)
(Genetic syndromes: Hereditary Nonpolyposis Colorectal Cancer (HNPCC) - Lynch II syndrome, Cowden syndrome)

Postmenopausal bleeding = endometrial cancer until proven otherwise (95% present with vaginal bleeding)

An endometrial thickness of 5 mm or more is considered abnormal in a postmenopausal woman with vaginal bleeding and a thickness of more than 11 mm is considered abnormal in a postmenopausal woman without vaginal bleeding

Screening
- no known benefit for mass screening
- annual endometrial sampling starting at age 30-35 only for patients at high risk (HNPCC/Lynch II syndrome)
- routine pelvic ultrasound should not be used as a screening test (high false positive rates)

Investigations
- endometrial sampling in all suspected patients (office endometrial biopsy most commonly)
- hysteroscopy considered in patients with persistent uterine bleeding with benign sampling or inadequate sampling
- additional tumour markers, CT, MRI only in specific cases, such as high-grade tumours or suspected extrauterine spread

Table 22. FIGO Staging of Endometrial Cancer (2009)

Stage	Description	Stage	Description
I	Confined to corpus uteri including endocervical glandular involvement	IIIC	Metastasis to pelvic ± para-aortic LNs
IA	Less than 50% myometrial invasion	IIIC1	Positive pelvic LN
IB	More than 50% myometrial invasion	IIIC2	Positive para-aortic LN ± positive pelvic LNs
II	Invades cervical stroma, but does not extend beyond uterus	IV	Invades bladder ± bowel mucosa ± distant metastases (note: omental disease is stage IV)
III	Involves serosa, adnexa, vagina, or parametrium	IVA	Invades bladder ± bowel mucosa
IIIA	Invasion of serosa ± adnexae	IVB	Distant metastases, including intra-abdominal and intraperitoneal metastases, ± inguinal LNs
IIIB	Vaginal ± parametrial involvement		

FIGO: International Federation of Gynecology and Obstetrics

Treatment
- surgical: total hysterectomy + BSO
  - pelvic washings ± pelvic and para-aortic node dissection ± omentectomy in more advanced cases
  - goals: treatment, staging, determining need for adjuvant treatment
- adjuvant therapy: includes radiation and chemotherapy, depends on clinical and histological features
- hormone therapy: can be used in fertility-sparing treatments (e.g. progesterone IUD or oral progestins)

UTERINE SARCOMA
- rare; 3-9% of all uterine malignancies
- arise from stromal components (endometrial stroma, mesenchymal, or myometrial tissues)
- behave more aggressively and are associated with worse prognosis than endometrial carcinoma; 5 yr survival is 35%
- vaginal bleeding is the most common presenting symptom

Prognostic Factors
- FIGO stage (most important factor)
- Age
- Grade
- Histologic subtype
- Depth of myometrial invasion
- Presence of LVSI

Complications of Therapy

Surgical Complications
- Surgical site infection
- Lymphedema
- VTE
- Urinary retention
- UTI
- Pelvic lymphocyst
- Leg weakness
- Vaginal dryness

Radiation Complications
- Radiation fibrosis
- Cystitis
- Proctitis
- Long-term increase in other types of malignancy

Uterine Sarcoma – Presentation
Bleeding, abdominal distention, pelvic pressure

CA-125 is indicated for monitoring response to treatment

Table 23. Summary of Uterine Sarcoma Subtypes and Features

Type	Epidemiology	Features	Diagnosis	Treatment
PURE TYPE				
1. Leiomyosarcoma	Most common type of uterine sarcoma Average age of presentation is 55 yr, but may present in premenopausal patients Often coexists with benign leiomyomata (fibroids)	Histologic distinction from leiomyoma: 1. Increased mitotic count (>10 mitoses/10 high-power fields) 2. Tumour necrosis 3. Cellular atypia Rapidly enlarging fibroids in a premenopausal patient Enlarging fibroids in a postmenopausal patient	Often postoperatively after uterus removed for presumed fibroids Stage using FIGO 2009 staging for leiomyosarcomas and ESS	Hysterectomy ± BSO usually No routine pelvic lymphadenectomy Chemotherapy is used in cases of metastatic disease Radiation therapy does not improve local control or survival Poor outcomes overall, even for early-stage disease
2. Endometrial Stromal Sarcoma (ESS)	Usually presents in perimenopausal or postmenopausal patients with abnormal uterine bleeding	Abnormal uterine bleeding Good prognosis	Diagnosed by histology of endometrial biopsy or D&C Stage using FIGO 2009 staging for leiomyosarcomas and ESS	Hysterectomy & BSO (remove ovaries as ovarian hormones may stimulate growth) No routine pelvic lymphadenectomy Adjuvant therapy based on stage and histologic features (hormones and/or radiation) Hormonal therapy (progestins) may be used for metastatic disease
3. Undifferentiated Sarcoma	Rare; less common than leiomyosarcoma and ESS	Severe nuclear pleomorphism, high mitotic activity, tumour cell necrosis, and lack of smooth muscle or endometrial stromal differentiation Poor prognosis	Often found incidentally postoperatively for abnormal bleeding	Treatment primarily surgical Radiation and/or chemotherapy for advanced diseased or unresectable disease
MIXED TYPE				
4. Adenosarcoma	The rarest of the uterine sarcoma Mixed tumour of low malignancy potential	Present with abnormal vaginal bleeding Polypoid mass in uterine cavity	Mixture of benign epithelium with malignant low-grade sarcoma Often found incidentally at time of hysterectomy for PMB Stage using FIGO 2009 staging for adenosarcoma	Treatment is surgical with hysterectomy & BSO

Table 24. FIGO Staging of Uterine Sarcoma (2009)

Stage	Description	Stage	Description
I	**Tumour limited to uterus**	**III**	**Tumour invades abdominal tissues**
IA	<5 cm	IIIA	One site
IB	>5 cm	IIIB	More than one site
II	**Tumour extends beyond uterus**	IIIC	Metastasis to pelvic and/or para-aortic lymph nodes
IIA	To the pelvis, adnexal involvement	**IV**	**Distant spread**
IIB	To extra-uterine pelvic tissue	IVA	Tumour invades bladder and/or rectum
		IVB	Distant metastasis

Ovaries are like GEMS
Germ cell
Epithelial
Metastatic
Sex cord stromal

Most (70%) epithelial ovarian cancers present at stage III disease

Ovary

BENIGN OVARIAN TUMOURS

- see *Table 25, GY45*
- many are asymptomatic
- usually enlarge slowly, if at all
- may rupture or undergo torsion, causing pain
  - pain associated with torsion of an adnexal mass usually originates in the iliac fossa and radiates to the flank
- peritoneal irritation may result from an infarcted tumour (rare)

Ovarian Tumour Markers
Epithelial cell:
- CA-125 (serous and endometrioid)

Sex-cord stromal cell:
- Granulosa cell: inhibin
- Sertoli-Leydig: androgens

Germ cell:
- Dysgerminoma: LDH
- Yolk sac: AFP
- Choriocarcinoma: β-hCG
- Immature teratoma: none
- Embryonal cell: AFP + β-hCG

MALIGNANT OVARIAN TUMOURS

- see *Table 25, GY45*

Diagnosis of ovarian tumours requires surgical pathology

Epidemiology

- lifetime risk 1.4%
- majority of ovarian cancer cases are detected in patients >50 yr
- causes more deaths in North America than all other gynecologic malignancies combined
- 4th leading cause of cancer death in women
- 85% epithelial; 15% non-epithelial
- 10-15% of epithelial ovarian cancers are related to hereditary predisposition

Any adnexal mass in postmenopausal women should be considered malignant until proven otherwise

Risk Factors (for epithelial ovarian cancers)

- early menarche and/or late menopause
- personal history of breast, colon, or endometrial cancer
- family history of breast, colon, endometrial, or ovarian cancer
- advanced age
- BRCA mutation (serous) and Lynch syndrome (non-serous, non-mucinous)
- use of fertility drugs (limited evidence)

Omental Cake: a term for ascites plus a fixed upper abdominal and pelvic mass; almost always signifies ovarian cancer

Protective Factors (for epithelial ovarian cancers)

- OCP: likely due to ovulation suppression (significant reduction in risk even after 1 yr of use, 50% after 5 yr)
- pregnancy/breastfeeding

Prophylactic Measures

- prophylactic BSO in high-risk patients (i.e. BRCA mutation carriers)
- prophylactic salpingectomy in high-risk patients (i.e. BRCA mutation carriers who do not want oophorectomy yet)

Screening

- no effective method
- routine CA-125 or U/S not recommended

Screening for Ovarian Cancer: Updated Evidence Report and Systematic Review for the US Preventive Services Task Force
JAMA 2018;319(6):595-606
Purpose: To systematically review evidence on benefits and harms of ovarian cancer screening among average-risk, asymptomatic women.
Methods: Systematic review of RCTs of ovarian cancer screening in average-risk women that reported mortality or quality-of-life outcomes. Interventions included transvaginal U/S and/or CA-125 testing. Comparators were usual care or no screening.
Results: Four trials (n = 293587) were included. No trial found a significant difference in ovarian cancer mortality with screening. In two trials, screening led to surgery for suspected ovarian cancer in 1% of women without cancer and for transvaginal U/S with or without CA-125 screening in 3%, with major complications occurring in 3% to 15% of surgeries. Evidence of psychological harm was found in cases of repeat follow-up scans and tests.
Conclusions: Ovarian cancer mortality did not significantly differ between screened women and those with no screening or in usual care.

Clinical Features

- most patients with epithelial ovarian cancer present with advanced stage disease (i.e. stage IIIC high-grade serous histology)
- symptoms:
  - abdominal symptoms (nausea, bloating, pain, dyspepsia, anorexia, early satiety)
  - symptoms of mass effect
  - increased abdominal girth (from ascites or tumour itself)
  - urinary urgency and frequency
  - constipation

Treatment

- debulking surgery including total hysterectomy, BSO, omentectomy, and/or removal of all visible disease
- many epithelial ovarian cancers (i.e. serous ovarian carcinoma) are chemosensitive: treat with platinum-based chemotherapy + taxol
- neo-adjuvant chemotherapy (if needed) to shrink down tumours prior to debulking
- adjuvant chemotherapy to treat microscopic disease

Malignant Ovarian Tumour Prognosis

5 Yr Survival	
Stage I	75-95%
Stage II	60-75%
Stage III	23-41%
Stage IV	11%

Low Malignant Potential (also called "Borderline") Tumours

- a subcategory of epithelial ovarian cancer (~15% of all epithelial ovarian tumours)
- approximately one-third of tumours are identified in patients <40 yr
- pregnancy and breastfeeding are protective factors
- tumour cells with histologically malignant characteristics arise from the ovarian surface, but do not invade the ovarian stroma
- able to metastasize, but uncommon
- treated primarily with surgery (BSO/omental biopsy ± hysterectomy)
  - chemotherapy has limited benefit: can be treated with hormonal manipulation (letrozole)
  - young patients can be treated with fertility-sparing options such as cystectomy or unilateral salpingo-oophorectomy
- generally slow growing, excellent prognosis
  - 5 yr survival >99%
  - recurrences tend to occur late, may be associated with low-grade serous carcinoma

Table 25. Ovarian Tumours

Type	Description	Presentation	Ultrasound/Cytology	Treatment
FUNCTIONAL TUMOURS (all benign)				
Follicular Cyst	Follicle fails to rupture during ovulation	Usually asymptomatic May rupture, bleed, tort, infarct, causing pain ± signs of peritoneal irritation	4-8 cm mass, unilocular, lined with granulosa cells	Symptomatic or suspicious masses warrant surgical exploration Otherwise if <6 cm, wait 6 wk then re-examine as cyst usually regresses with next cycle OCP (ovarian suppression): will prevent development of new cysts Treatment usually laparoscopic (cystectomy vs. oophorectomy, based on fertility choice)
Corpus Luteum Cyst	Corpus luteum fails to regress after 14 d, becoming cystic or hemorrhagic	More likely to cause pain than follicular cyst May delay onset of next period	Larger (10-15 cm) and firmer than follicular cysts	Same as for follicular cysts
Theca-Lutein Cyst	Due to atretic follicles, stimulated by abnormal β-hCG levels	Associated with molar pregnancy, ovulation induction with clomiphene		Conservative Cyst will regress as β-hCG levels fall
Endometrioma	See *Endometriosis, GY11*			
Polycystic Ovaries	See *Polycystic Ovarian Syndrome, GY25*			
BENIGN GERM CELL TUMOURS				
Benign Cystic Teratoma (dermoid)	Single most common ovarian germ cell neoplasm Elements of all 3 cell lines; contains dermal appendages (sweat and sebaceous glands, hair follicles, teeth)	May rupture, twist, infarct 20% bilateral 20% occur outside of reproductive yr	Smooth-walled, mobile, unilocular U/S may show calcification which is pathognomonic	Treatment usually laparoscopic cystectomy; may recur
MALIGNANT GERM CELL TUMOURS				
General Information	Rapidly growing, 2-3% of all ovarian cancers	Usually children and young women (<30 yr)		Surgical resection (often conservative unilateral salpingo-oophorectomy ± nodes) ± chemotherapy
Dysgerminoma	Produces LDH	10-15% bilateral		When diagnosed at stage IA, no adjuvant treatment is indicated If diagnosed at advanced stage, very responsive to chemotherapy, therefore complete resection is not necessary for cure
Immature Teratoma	No tumour marker identified	Almost always unilateral		When diagnosed at stage IA Grade 1, no adjuvant treatment is indicated When diagnosed at Grade 2-3, either adjuvant chemotherapy or surgical staging is indicated If diagnosed at advanced stage, very responsive to chemotherapy, therefore complete resection is not necessary for cure
Yolk Sac Tumour	Produces AFP	Abdominal pain and pelvic mass		High grade tumour can be treated with adjuvant chemotherapy or monitor AFP levels
Ovarian Choriocarcinoma	Produces β-hCG	Precocious puberty and irregular vaginal bleeding		High grade tumour usually treated with adjuvant chemotherapy

Table 25. Ovarian Tumours

Type	Description	Presentation	Ultrasound/Cytology	Treatment
EPITHELIAL OVARIAN TUMOURS (malignant or borderline)				
General Information	Derived from mesothelial cells lining peritoneal cavity Classified based on histologic type 80-85% of all ovarian neoplasms (including malignant tumours)		Varies depending on subtype	**Borderline** Cystectomy vs. unilateral salpingo-oophorectomy **Malignant** 1. Early stage (stage I): Hysterectomy/BSO/staging (omentectomy, peritoneal biopsies, washings, pelvic and para-aortic lymphadenectomy). Depending on histology, may require adjuvant chemotherapy 2. Advanced stage: Upfront cytoreductive (debulking) followed by adjuvant chemotherapy consisting of IV carboplatin/paclitaxel vs. intraperitoneal chemotherapy (stage III) neoadjuvant chemotherapy with IV carboplatin/paclitaxel, followed by delayed debulking with further adjuvant IV chemotherapy
Serous	Most common ovarian tumour histology 50% of all ovarian cancers 75% of epithelial tumours 70% benign	20-30% bilateral	Lining similar to fallopian tube epithelium Often multilocular Histologically contain psammoma bodies (calcified concentric concretions)	See above
Mucinous	20% of epithelial tumours	Rarely complicated by Pseudomyxoma peritonei: implants seed abdominal cavity and produce large quantities of mucin	Resembles endocervical epithelium Often multilocular May reach enormous size	Poor response to chemotherapy If mucinous, remove appendix as well to rule out possible source of primary disease
Clear Cell	10% of epithelial tumours Can be found adjacent to endometriosis More common in the Asian population	More likely to be detected at an early stage	Contains glycogen-rich cells with clear cytoplasm and hobnail cells	Poor response to chemotherapy
Endometrioid	10% of epithelial tumours Can be found adjacent to endometriosis	Can be associated with endometrial neoplasm	Typically cystic or solid, unilateral, and confined to the ovary	Tend to respond well to chemotherapy
SEX CORD STROMAL OVARIAN TUMOURS				
Fibroma/Thecoma (benign)	From mature fibroblasts in ovarian stroma	Non-functioning Occasionally associated with Meig's syndrome (triad of benign ovarian tumour, ascites, and pleural effusion)		
Granulosa-Theca Cell Tumours (benign or malignant)	Tumour marker is inhibin	Estrogen-producing: feminizing effects (precocious puberty, menorrhagia, postmenopausal bleeding) Risk of endometrial cancer due to estrogen	Histologic hallmark of cancer is small groups of cells known as Call-Exner bodies	Surgical resection of tumour Chemotherapy may be used for unresectable metastatic disease
Sertoli-Leydig Cell Tumour (benign or malignant)	Can measure elevated androgens as tumour markers	Androgen-producing: virilizing effects (hirsutism, deep voice, recession of front hairline)		Surgical resection of tumour Chemotherapy may be used for unresectable metastatic disease
METASTATIC OVARIAN TUMOURS				
From GI Tract, Breast, Endometrium, Lymphoma	4-8% of ovarian malignancies Krukenberg tumour: metastatic ovarian tumour (usually GI tract, commonly stomach or colon, breast primary tumour)	80% bilateral	Krukenberg tumours have "signet-ring" cells	

Investigation of Suspicious Ovarian Mass

- women with suspected ovarian cancer based on history, physical, or investigations should be referred to a gynecologic oncologist
  - bimanual examination
    - solid, irregular, or fixed pelvic mass is suggestive of ovarian cancer
  - RMI (Risk of Malignancy Index) is best tool available to assess likelihood of ovarian malignancy and need for preoperative gynecologic oncology referral (see sidebar)
- physical exam findings largely dependent on stage of disease
- blood work: CBC, LFTs, electrolytes, Cr, tumour markers as appropriate (CA-125, inhibin, β-hCG, LDH, AFP, androgens, CEA, Ca19-9, estrogen)
- biopsy not recommended due to tumour spillage into peritoneum; if extensive disease, determine cytological diagnosis from paracentesis from ascites or tissue biopsy from peritoneal deposits or omental cake
- radiology
  - transvaginal U/S best to visualize ovaries
  - CT abdomen and pelvis to look for metastatic disease
  - bone scan or PET scan not indicated

Causes of Elevated CA-125

Age influences reliability of test as a tumour marker

50% sensitivity in early-stage ovarian cancer (poor), therefore not good for screening

Malignant

Gynecologic: ovary, uterus

Non-Gynecologic: pancreas, stomach, colon, rectum

Non-Malignant

Gynecologic: benign ovarian neoplasm, endometriosis, pregnancy, fibroids, PID

Non-Gynecologic: cirrhosis, pancreatitis, renal failure

- try to rule out other primary source (if suspected), based on:
  - occult blood per rectum: endoscopy ± barium enema
  - gastric symptoms: gastroscopy ± upper GI series
  - abnormal vaginal bleeding: endometrial biopsy to rule out concurrent endometrial cancer; abnormal cervix: need to biopsy cervix (not Pap smear); breast lesion identified or risk factors present: mammogram

Table 26. FIGO Staging for Primary Carcinoma of the Ovary (Surgical Staging) (2014)

Stage	Description
I	Growth limited to the ovaries
IA	1 ovary, no ascites, no tumour on external surface, capsule intact, negative washings
IB	2 ovaries, no ascites, no tumour on external surface, capsule intact
IC	1 or 2 ovaries with any of the following: surgical spill (IC1), capsule ruptured (IC2), tumour on ovarian surface (IC2), or malignant cells in ascites (IC3)
II	**Growth involving one or both ovaries with pelvic extension or primary peritoneal cancer**
IIA	Extension ± implants to uterus/tubes
IIB	Extension to other pelvic structures
III	**Tumour involving one or both ovaries with peritoneal implants outside the pelvis and/or positive retroperitoneal nodes**
IIIA	Positive retroperitoneal LNs and/or microscopic metastasis beyond pelvis
IIIA1	Positive retroperitoneal LNs
IIIA2	Microscopic, extrapelvic peritoneal involvement ± positive retroperitoneal LNs
IIIB	Macroscopic peritoneal metastasis beyond pelvis ≤2 cm, ± positive retroperitoneal LNs. Includes extension to capsule of liver/spleen
IIIC	Same as above but peritoneal metastasis >2 cm
IV	**Distant metastasis beyond peritoneal cavity**
IVA	Pleural effusion with positive cytology
IVB	Hepatic and/or splenic parenchymal metastasis or metastasis to extra-abdominal organs (inguinal LNs and LNs outside of abdominal cavity included)

FIGO = International Federation of Gynecology and Obstetrics

Cervix

MALIGNANT CERVICAL LESIONS

Epidemiology

- majority are SCC (90%); adenocarcinomas increasing (10%); rare subtypes include small cell, adenosquamous
- 8000 deaths annually in North America
- average age at presentation: 50 yr; bimodal distribution (increased frequency in 40s and 60s)

Etiology

- at birth, the vagina is lined with squamous epithelium; columnar epithelium lines only the endocervix and the central area of the ectocervix (original squamocolumnar junction)
- during puberty, estrogen stimulates eversion of a single columnar layer (ectopy), thus exposing it to the acidic pH of the vagina, leading to metaplasia (change of exposed epithelium from columnar to squamous)
  - a new squamocolumnar junction forms as a result
- the TZ is the area located between the original and the current squamocolumnar junction
- the majority of dysplasias and cancers arise in the TZ of the cervix
- must have active metaplasia in presence of inducing agent (e.g. HPV) to get dysplasia
- dysplasia progresses to carcinoma *in situ* (CIS), which further progresses to invasion of cervical tissues
- slow process (~10 yr on average)
- growth is by local extension
- metastasis occurs late

Risk Factors

- HPV infection
  - see *Sexually Transmitted Infections, GY28*
  - high-risk of neoplasia associated with types 16, 18, 31, 33, 35, 39, 45, 51, 52, 56, 58, 59, 68, 73, and 82
  - low-risk of neoplasia associated with types 6, 11
  - >99% of cervical cancers contain one of the high-risk HPV types
- high-risk behaviours (risk factors for HPV infection)
  - multiple partners
  - other STIs (HSV, trichomonas)
  - early age at first intercourse
  - high-risk male partner

A Risk of Malignancy Incorporating CA-125, Ultrasound, and Menopausal Status for the Accurate Preoperative Diagnosis of Ovarian Cancer
BJOG 1990;97:922-929
RMI = U x M x CA-125
Ultrasound Findings (1 pt for each)
- Multilocular cyst
- Evidence of solid areas
- Evidence of metastases
- Presence of ascites
- Bilateral lesions

U = 1 (for U/S scores of 0 or 1)
U = 4 (for U/S scores of 2-5)
Menopausal Status
- Postmenopausal: M = 4
- Premenopausal: M = 1

Absolute Value of CA-125 Serum Level
- For RMI>200: gynecologic oncology referral is recommended

Optimal Primary Surgical Treatment for Advanced Epithelial Ovarian Cancer
Cochrane Database Syst Rev 2011;(8):CD007565
Summary: During primary surgery for stage III or IV epithelial ovarian cancer, all attempts should be made to achieve complete cytoreduction. When this is not achievable, optimal (<1 cm) residual disease should be the goal.
Methods: Identified 11 retrospective studies consisting of 4735 women using comprehensive search strategy.
Results:
1. When suboptimal (margins >1 cm) was compared with optimal (<1 cm) cytoreduction, the survival estimates were reduced but remained statistically in favour of the lower volume disease group.
2. No significant difference in overall survival between suboptimal and optimal cytoreduction.
3. Borderline difference in progression-free survival when residual disease >2 cm and <2 cm were compared (p=0.05).

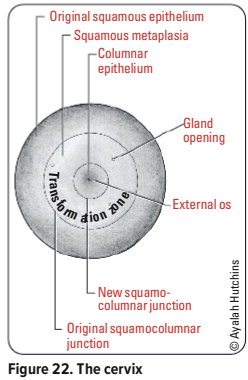

Figure 22. The cervix

Cervical cancer is most prevalent in developing countries and, therefore, is the only gynecologic cancer that uses clinical staging; this facilitates consistent international staging with countries that do not have technologies such as CT and MRI

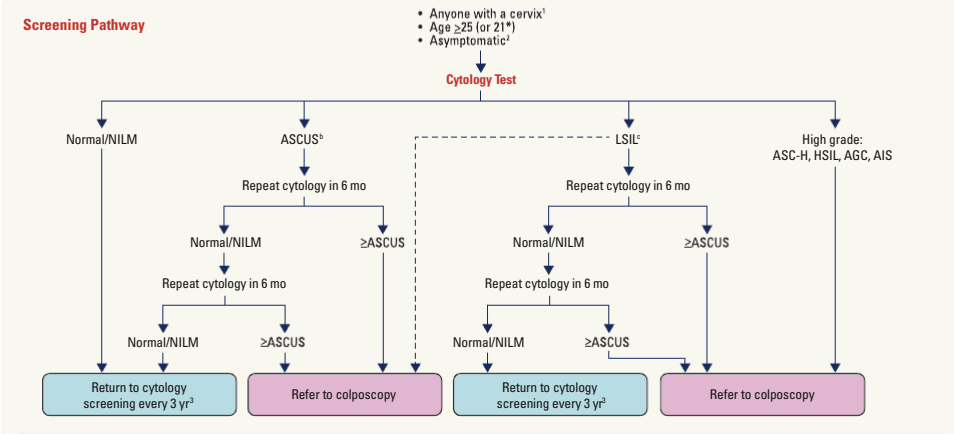
- smoking
- poor screening uptake is the most important risk factor for cervical cancer in Canada
- at-risk groups include:
  - immigrant Canadians
  - Indigenous peoples in Canada
  - geographically-isolated Canadians
  - sex-trade workers
  - low socioeconomic status Canadians
  - immunocompromised individuals

Cervical Cancer Screening Guidelines (Pap Test)

- see Family Medicine, FM5

Clinical Features

- SCC: exophytic, fungating tumour
- adenocarcinoma: endophytic or exophytic, with barrel-shaped cervix
- early
  - asymptomatic
  - discharge: initially watery, becoming brown or red
  - postcoital bleeding
- late
  - 80-90% present with bleeding: either postcoital, postmenopausal, or irregular bleeding
  - pelvic or back pain (extension of tumour to pelvic walls)
  - bladder/bowel symptoms
- signs
  - friable, raised, reddened, or ulcerated area visible on cervix



[1]These guidelines apply to anyone with a cervix including: women; pregnant people; transmen; non binary people; people who have undergone a subtotal hysterectomy; and people who have been vaccinated with the HPV vaccine
[2]Any visible cervical abnormalities or abnormal symptoms must be investigated. Consider referral to a specialist (e.g. colposcopist, gynaecologist, gynaeoncologist)
[3]Immunocompromised people may be at elevated risk and should receive annual screening
[a]Ontario Health (Cancer Care Ontario) is aware that the Screening Activity Report is not yet aligned with this guidance and will be updated with HPV implementation. Criteria for preventive care bonuses may not be updated during the interim period of changeover to HPV testing. Criteria for preventive care bonuses will be updated when HPV testing is implemented in screening
[b]HPV testing is not currently funded by the Ministry of Health. Primary care providers can consider HPV testing for those with ASCUS results on a patient pay basis or where available (i.e. in some hospital settings) for people ages 30 and older
[c]Repeat cytology or colposcopy are acceptable management options after the first LSIL result. Low grade abnormalities often regress on their own and may be best managed in surveillance, however colposcopy may be considered

Figure 23. Decision making chart for Pap test (not applicable for adolescents)

Adapted from: Ontario Cervical Screening Program. June 2020. Cervical screening guidelines unique to each province

Diagnosis

- colposcopy is a clinical procedure that facilitates identification and biopsy of suspicious cells
- in colposcopy:
  - apply acetic acid and identify acetowhite lesions, punctation, mosaicism, and abnormal blood vessels to guide cervical biopsy
  - ECC if entire lesion is not visible or no lesion visible
  - diagnostic excision (LEEP) if:
    - unsatisfactory colposcopy (poor visualization/access to transformation zone)
    - discrepancy between cytology, colposcopy, and histological findings
    - positive findings/glandular abnormalities in endocervical curettage
    - suspicious for adenocarcinoma *in situ* (consider cold-knife conization)
    - recurrence of lesion post-ablation or excision
    - inability to rule out invasive disease, i.e. large lesions (lesions extending into endocervical canal, extending widely on cervix, or onto vaginal epithelium)
- consider cold-knife conization (in OR) if glandular abnormality suspected based on cytology or colposcopic findings due to concern for margin interpretation
- any imaging modality or pathological findings are permitted for FIGO clinical staging

Table 27. FIGO Staging Classification of Cervical Cancer (Clinical Staging) (2018)

Stage	Description
I	**Confined to cervix**
IA	Diagnosed only by microscopy
IA1	Stromal invasion not >3 mm deep
IA2	3 mm to <5 mm deep
IB	Measured deepest invasion ≥5 mm (greater than stage IA), lesion limited to cervix
IB1	Stromal invasion ≥5 mm deep and <2 cm wide
IB2	Stromal invasion ≥5 mm deep and ≥2 cm and <4 cm wide
IB3	≥4 cm in width
II	**Beyond uterus but not to the pelvic wall or lower 1/3 of vagina**
IIA	Limited to upper 2/3 of vagina, no obvious parametrial involvement
IIA1	Clinically visible lesion <4 cm wide
IIA2	Clinically visible lesion ≥4 cm wide
IIB	Obvious parametrial involvement, but not up to pelvic wall
III	**Extends to pelvic wall, and/or involves lower 1/3 of vagina, and/or causes hydronephrosis or non-functioning kidney, and/or involves pelvic and/or para-aortic lymph nodes**
IIIA	Involves lower 1/3 vagina but no extension into pelvic wall
IIIB	Extension into pelvic side wall and/or hydronephrosis or non-functioning kidney
IIIC	Involvement of pelvic and/or para-aortic lymph nodes, irrespective of tumour size and extent
IIIC1	Pelvic lymph nodes metastasis only
IIIC2	Para-aortic lymph node metastasis
IV	**Carcinoma has extended beyond true pelvis or has involved (biopsy proven) the mucosa of the bladder or rectum (bullous edema does not permit a case to be allotted to stage IV)**
IVA	Spread of the growth to adjacent organs (bladder or rectum)
IVB	Distant metastases

Treatment: Prevention and Management

Prevention: HPV Vaccine

- two vaccines currently approved (Gardasil®, Cervarix®)

Table 28. Comparison of Two Vaccines against Human Papillomavirus (HPV)

	Gardasil®*	Cervarix®
Viral Strains Covered	6, 11, 16, 18, 31, 33, 45, 52, and 58	16, 18
Route of Administration	IM	IM
Schedule of Dosing	2 Dose: Second dose administered 6-12 mo after first dose 3 Dose: 0, 2, 6 mo	0, 1, 6 mo
Side Effects	Local: redness, pain, swelling General: headache, low grade fever, GI upset	Local: redness, pain, swelling General: headache, low grade fever, GI upset
Approved Age	Females ages 9-45, males ages 9-45	Females ages 9-45
Contraindications	Pregnancy and breastfeeding (limited data)	

*Gardasil-9 also covers types 31, 33, 45, 52, and 58; also used to prevent genital warts

The Bethesda Classification System is based on cytological results of a Pap test that permits the examination of cells but not tissue structure. LSIL, HSIL, or cervical carcinoma is a histological diagnosis, requiring a tissue sample via biopsy of suspicious lesions seen during colposcopy

Cervical Cancer Prognosis 5 yr Survival	
Stage 0	99%
Stage I	75%
Stage II	55%
Stage III	30%
Stage IV	7%
Overall	50-60%

Final Efficacy, Immunogenicity, and Safety Analyses of a Nine-Valent Human Papillomavirus Vaccine in Women Aged 16-26 Years: A Randomised, Double-Blind Trial
Lancet 2017;390:2143-2159
Purpose: A nine-valent HPV vaccine (9vHPV) was developed which covers additional strains of HPV compared to the quadrivalent vaccine (qHPV). This study reported the efficacy of the 9vHPV vaccine.
Methods: A randomized double-blind efficacy trial comparing the nine-valent HPV vaccine (9vHPV) to the quadrivalent HPV vaccine (qHPV) in 14215 women. The primary outcomes were incidence of high-grade cervical, vulvar, and vaginal diseases related to HPV-31, 33, 45, 52, and 58 and non-inferiority of anti-HPV 6, 11, 16, and 18 mean titres.
Results: The incidence of high-grade cervical, vulvar, and vaginal disease was 0.5 cases per 10000 person-yr for the 9vHPV group compared to 19 cases per 10000 person-yr for the qHPV group. HPV 6, 11, 16, and 18 titres were non-inferior in the 9vHPV group compared to the qHPV group. There were no clinically meaningful differences in severe adverse effects between groups.
Conclusions: The 9vHPV vaccine is effective at preventing infection, cytological abnormalities, and high-grade lesions and may offer broader protection against HPV and cervical cancer compared to the qHPV vaccine.

- should be administered before onset of sexual activity (i.e. before exposure to virus) for optimal benefit of vaccination
- may be given at the same time as hepatitis B or other vaccines using a different injection site
- not for treatment of active infections
- most patients will not be infected with all four types of the virus at the same time, therefore vaccine is still indicated for sexually active females or those with a history of previous HPV infection or HPV-related disease

Abnormal Pap Tests in Pregnancy

- incidence: 1 in 2200
- Pap test at initial prenatal visit if overdue for routine Pap test
  - if abnormal Pap or suspicious lesion, refer to colposcopy
  - if diagnostic conization required, should be deferred until T2 to minimize risk of pregnancy loss
  - if invasive cancer ruled out, management of dysplasia deferred until completion of pregnancy (may deliver vaginally)
  - if invasive cancer present, management depends on prognostic factors, degree of fetal maturity, and patient wishes
    - general recommendations in T1: consider pregnancy termination, management with either radical surgery (hysterectomy vs. trachelectomy if desires future fertility), or concurrent chemoradiation therapy
    - recommendations in T2/T3: delay of therapy until viable fetus and C-section for delivery with concurrent radical surgery or subsequent concurrent chemoradiation therapy

Table 29. Management of Abnormal Cervical Histology and Cervical Cancer

Histology Result from Colposcopy	Management
Normal	If histology results normal and cytology > LSIL, then repeat colposcopy in 6 mo
LSIL	**Women <25 yr** If cytology is LSIL, ASCUS, or normal, then annual Paps by primary care provider x 3 yr, followed by return to normal screening If cytology is HSIL, then consider pathology review, and/or reassessment every 6-12 mo in colposcopy **Women ≥ 25 yr** If HPV -: routine Pap screening every 3 yr If HPV +: follow-up colposcopy with cytology and HPV test (if 30 yr or older) in 1 yr
HSIL CIN II/CIN III	**Women ≥25 yr** Excisional procedures (e.g. cold knife, LEEP) or laser preferred Those with positive margins should have follow-up with colposcopy and directed biopsies and/or endocervical curettage **Women <25 yr** Colposcopy every 6 mo for 2 yr or treatment may be acceptable based on patient preference
AIS	Repeat colposcopy + treatment (e.g. LEEP, cold-knife cone) ± endocervical curettage
Stage IA1 (no LVSI)	LEEP if future fertility desired (and lesion ≤2 cm) Simple hysterectomy if future fertility is not desired
Stage IA2, IB1, IB2	Typically treated with radical hysterectomy and pelvic lymphadenectomy (sentinel nodes or pelvic lymph node dissection) If high chance of adjuvant radiation then consider primary chemoradiation as more morbidity occurs from double-modality treatment (surgery and radiation) Equal cure rates may be obtained with primary radiation therapy; advantage of surgery: may accurately stage and grade and more targeted adjuvant therapy Advantage is that ovaries can be spared if premenopausal, better sexual functioning For fertility preservation (if tumour <2 cm), may have radical trachelectomy (removal of cervix and parametria) and nodes instead of radical hysterectomy for early-stage disease Chemoradiation therapy if adverse high-risk prognostic factors on radical surgical specimen, such as: positive pelvic lymph nodes, positive parametria, and/or positive margins or adverse cervical factors (2 or more): deep stromal invasion, size >4 cm, LVSI
Stages IB3 (>4 cm), II, III, IV	Primary chemoradiation therapy CT to assess extent of disease: evaluate pelvic and para-aortic nodes For positive nodes on PET: primary chemoradiation with extended field RT Hysterectomy generally not suggested following primary treatment with curative intent

Fallopian Tube

- least common site for carcinoma of the female reproductive system (0.3%)
- usually serous epithelial carcinoma
- new evidence shows that some serous ovarian cancers originate in the fallopian tube
- more common in fifth and sixth decade

Clinical Features

- classic triad present in minority of cases, but very specific
  - watery discharge (most specific): "hydrops tubae profluens"
  - vaginal bleeding or discharge in 50% of patients
  - crampy lower abdominal/pelvic pain

- most patients present with a pelvic mass (see *Pelvic Mass, GY42* and *Ovary, GY44* for guidelines regarding diagnosis/investigation)

Treatment
- same as for malignant epithelial ovarian tumours, see *Table 25, GY45*
- salpingectomy (removal of fallopian tubes to prevent ovarian cancer)

Vulva

BENIGN VULVAR LESIONS

Non-Neoplastic Disorders of Vulvar Epithelium
- biopsy is often necessary to make diagnosis and/or rule out malignancy:
  1. Lichen sclerosus
     - subepithelial fat becomes diminished; labia become thin, atrophic, with membrane-like epithelium and labial fusion
     - pruritus, dyspareunia, burning, bleeding, ulceration, excoriations
     - 'figure of 8' distribution
     - most common in postmenopausal patients but can occur at any age
     - patients should be monitored for malignancy, due to increased risk of SCC
     - treatment: high-potency topical steroid ointment (clobetasol), likely long-term treatment necessary
  2. Lichen simplex chronicus
     - surface of labia majora is thickened and hyperkeratotic, leather-like in appearance
     - most common symptoms: pruritus and burning, often at night
     - typically occurs in postmenopausal patients
     - treatment: medium-potency steroid ointment based on symptom severity + nighttime antihistamines
  3. Lichen planus
     - autoimmune disorder where T cells attack basal keratinocytes
     - peak incidence at age 30-60
     - 3 variants including erosive, papulosquamous, and hypertrophic
     - can extend into vaginal canal and cause loss of structure (desquamative vaginitis)
     - can have oral lichen planus in oral cavity
     - treatment: ultrapotent steroid ointment BID until plaques resolve, vaginal suppositories, or immunosuppressive therapies (e.g. cyclosporine) are all accepted

Any suspicious lesion of the vulva should be biopsied

Tumours
- papillary hidradenoma, nevus, fibroma, hemangioma

MALIGNANT VULVAR LESIONS

Epidemiology
- 5% of genital tract malignancies
- 90% SCC; remainder melanomas, basal cell carcinoma, Paget's disease, Bartholin's gland carcinoma
  - Type I disease: HPV-related (50-70%), usual or classical vulvar intraepithelial neoplasia (VIN)
    - more likely in younger patients
    - 90% of VIN contain HPV DNA (usually types 16, 18)
  - Type II disease: not HPV-related, associated with current or previous vulvar dystrophy, differentiated VIN
    - usually postmenopausal patients
    - related to lichen sclerosis

Risk Factors
- HPV infection
- VIN: precancerous change which presents as multicentric white or pigmented plaques on vulva (may only be visible at colposcopy)
- progression to cancer rarely occurs with appropriate management
  - treatment: local excision (i.e. superficial vulvectomy ± split thickness skin grafting to cover defects if required) vs. ablative therapy (i.e. laser, cauterization) vs. local immunotherapy (imiquimod)
- history of cervical cancer
- cigarette smoking
- immunodeficiency
- vulvar lichen sclerosus

Clinical Features
- most lesions occur on the labia majora, followed by the labia minora (less commonly on the clitoris or perineum)
- localized pruritus, or white, red, or skin coloured papules, nodules, or plaques most common
- less common: ulcer, bleeding, discharge, pain, and dysuria
- patterns of spread
  - local
  - groin lymph nodes (usually inguinal, then spreading to pelvic nodes)
  - hematogenous

Investigations
- ± vulvar biopsy
- always biopsy any suspicious lesion
  - do not remove entire lesion during biopsy (allows for site identification through sentinel LN injection if malignant)

Prognosis
- depends on stage: particularly nodal involvement (single most important predictor followed by tumour size)
  - lesions >4 cm associated with poorer prognosis
- overall 5 yr survival rate: 79%

Treatment
- FIGO Stage I (tumour confined to vulva; no extension to adjacent perineal structures): radical local excision
- FIGO Stage II (tumour of any size with extension to adjacent perineal structures, no nodal metastases): modified radical vulvectomy
- FIGO stage III-IV (extension to any of: proximal 2/3 of urethra, proximal 2/3 of the vagina, bladder mucosa, rectal mucosa, or fixed to pelvic bone, or large/distant nodal metastases): sentinel lymph node biopsy followed by surgical resection of residual primary and adjuvant chemotherapy or radiation

Vagina

BENIGN VAGINAL LESIONS
- inclusion cysts
  - cysts form at site of abnormal healing of laceration (e.g. episiotomy)
  - no treatment required
- endometriosis
  - dark lesions that tend to bleed at time of menses
  - treatment: excision
- Gartner's duct cysts
  - remnants of Wolffian duct seen along side of cervix
  - treatment: conservative unless symptomatic
- urethral diverticulum
  - can lead to recurrent urethral infection, dyspareunia
  - treatment: surgical correction if symptomatic

MALIGNANT VAGINAL LESIONS

Epidemiology
- primary carcinomas of the vagina represent 2-3% of malignant neoplasms of the female genital tract
- 80-90% are SCC
- more than 50% diagnosed between 70-90 yr

Risk Factors
- associated with HPV infection (analogous to cervical cancer)
- increased incidence in patients with prior history of cervical and vulvar cancer

Investigations
- cytology
  - significant false negative rate for existing malignancy (i.e. if gross lesion present, biopsy)
- colposcopy
- Schiller test (normal squamous epithelium takes up Lugol's iodine)
- biopsy, partial vaginectomy (wide local excision for diagnosis)
- rule out disease on cervix, vulva, or anus (most vaginal cancers are metastatic from one of these sites)
- staging

Clinical Features

Table 30. Clinical Features of Malignant Vaginal Lesions

Type	Clinical Features
Vaginal Intra-Epithelial Neoplasia (VAIN)	Grades: analogous to cervical dysplasia
Squamous Cell Carcinoma (SCC)	Most common site is upper 1/3 of posterior wall of vagina Asymptomatic Painless vaginal discharge (often foul-smelling) and bleeding Vaginal bleeding especially during/post-coitus Urinary and/or rectal symptom 2° to compression
Adenocarcinoma	Most are metastatic, usually from cervix, endometrium, ovary, or colon Most primaries are clear-cell adenocarcinomas Two types: non-DES and DES syndrome

Treatment
- Stage I
  - radiation therapy: for tumours >2 cm diameter or tumour involvement of the middle or lower vagina
  - surgical excision: radical hysterectomy, upper vaginectomy, and bilateral pelvic lymphadenectomy
- Stage II-IV: primary radiation with or without chemotherapy

Gestational Trophoblastic Disease/Neoplasia

- refers to a spectrum of proliferative abnormalities of the trophoblast
- GTD = abnormal, can be benign or lead to the malignant form, called GTN

Epidemiology
- 1/1000 pregnancies
- marked geographic variation (as high as 1/125 in Taiwan)
- 80% benign, 15% locally invasive, 5% metastatic
- cure rate >95%

HYDATIDIFORM MOLE (GTD)

Complete Mole
- most common type of hydatidiform mole
- risk factors
  - geographic (most common in those of South East Asian background)
  - others (maternal age >40 yr, β-carotene deficiency, vitamin A deficiency not proven)
  - prior molar pregnancy

With development of HTN early in pregnancy (i.e. <20 wk), think gestational trophoblastic disease

Partial (or Incomplete) Mole
- associated with fetus, which may be growth-restricted, and/or have multiple congenital malformations

Table 31. Features of Complete and Incomplete Hydatidiform Moles

	Complete	Incomplete
Pathology	Diffuse trophoblastic hyperplasia	Focal trophoblastic hyperplasia
Presence of Fetus	None	Associated with fetal tissue
Ultrasound Features	"Snowstorm" appearance due to swelling of villi	Degeneration of placenta Multiple echogenic regions Focal intrauterine hemorrhage
Genetics	Diploid Chromosomes completely of paternal origin	Triploid 1 set of maternal chromosomes 2 sets of paternal chromosomes
Clinical Presentation	Vaginal bleeding Uterine size large for dates Hyperemesis gravidarum Preeclampsia Hyperthyroid	Similar to spontaneous, threatened, missed abortion Vaginal bleeding
Risk of Progression of Malignancy	15-20%	<4%

Investigations
- quantitative β-hCG levels (tumour marker) abnormally high for gestational age
- CXR (may show metastatic lesions)
- features of molar pregnancies at high-risk of developing persistent GTN post-evacuation
  - local uterine invasion as high as 31%
  - β-hCG >100000 IU/L
  - excessive uterine size
  - prominent theca-lutein cysts >6 cm in diameter

Treatment
- for GTD: suction D&C (or rarely hysterectomy)
- Rhogam® if Rh-negative
- for GTN: single agent (i.e. methotrexate, actinomycin D) or multi-agent (i.e. EMACO, EMA-EP) chemotherapy based on WHO scoring system

Follow-up
- serial β-hCGs (as tumour marker) every week until negative x 3 (usually takes several wk), and then one month after for incomplete hydatidiform mole or monthly for 6 mo if complete hydatidiform mole
- reliable contraception required to avoid pregnancy during entire follow-up period
- women who become pregnant during the follow-up period should be referred to gynecologic oncology and maternal-fetal medicine specialists
- increase or plateau of β-hCG indicates GTN: single or multi-agent chemotherapy based on WHO scoring system (see *Table 32*)

Table 32. WHO Prognostic Score for GTD (2011)

	Score			
Prognostic Factor	**0**	**1**	**2**	**4**
Maternal Age	<40	≥40		
Antecedent Pregnancy	Mole	Abortion	Term	
Interval (End of Antecedent Pregnancy to Chemotherapy in Months)	<4	4-6	7-13	>13
HCG IU/L	$<10^3$	10^3-10^4	10^4-10^5	$>10^5$
Number of Metastases	0	1-4	5-8	>8
Site of Metastases	Lung	Spleen, kidney	GI tract	Brain, liver
Largest Tumour Mass		3-5 cm	>5 cm	
Prior Chemotherapy			Single drug	Two drugs

A score of 6 or less is considered low-risk GTD. A score of 7 or more is considered high-risk GTD. A score of ≥ 13 is considered ultra high-risk GTD. The prognostic factor score is recorded after the FIGO score stage, separated by a colon

GTN (MALIGNANT GTD)

GTN Diagnosis
- β-hCG rise >10% compared with previous levels over 2 wk (e.g. 3 levels measured on days 1, 8, and 15) OR
- β-hCG plateau: <10% change/plateau compared with previous levels over 3 wk (e.g. 4 levels measured on days 1, 8, 15, and 22) OR
- histologic diagnosis of choriocarcinoma OR
- metastatic disease OR
- β-hCG level ≥20 000 mIU/mL >4 wk post-evacuation

Invasive Mole or Persistent GTN
- development of metastases following treatment of documented molar pregnancy
- histology: molar tissue from D&C
- metastases are rare (4%)

Choriocarcinoma
- often presents with symptoms from metastases
- highly anaplastic, highly vascular
- no chorionic villi, elements of syncytiotrophoblast and cytotrophoblast
- may follow molar pregnancy, miscarriage, therapeutic abortion, ectopic pregnancy, or normal pregnancy

Placental-Site Trophoblastic Tumour
- rare aggressive form of GTN
- abnormal growth of intermediate trophoblastic cells
- low β-hCG, production of human placental lactogen (hPL), relatively insensitive to chemotherapy

Classification of GTN
- non-metastatic
  - ~15% of patients after molar evacuation
  - may present with abnormal bleeding
  - all have rising or plateau of β-hCG
  - negative metastases on staging investigations
- metastatic
  - 4% of patients after treatment of complete molar pregnancy
  - metastasis more common with choriocarcinoma, which tends toward early vascular invasion and widespread dissemination

- if signs or symptoms suggest hematogenous spread, do not biopsy (they bleed)
  - lungs (80%): cough, hemoptysis, CXR lesion(s)
  - vagina (30%): vaginal bleeding, "blue lesions" on speculum exam
  - pelvis (20%): rectal bleeding (if invades bowel), U/S lesion(s)
  - liver (10%): elevated LFTs, U/S, or CT findings
  - brain (10%): headaches, dizziness, seizure (symptoms of space-occupying lesion), CT/MRI findings
- highly vascular tumour, which is more likely to bleed and result in anemia
- all have rising or plateau of β-hCG
- classification of metastatic GTN
  - divided into good prognosis and bad prognosis
  - features of bad prognosis
    - long duration (>4 mo from antecedent pregnancy)
    - high pre-treatment β-hCG titre: >100000 IU/24 h urine or >40000 IU/L of blood
    - brain or liver metastases
    - prior chemotherapy
    - metastatic disease following term pregnancy
  - good prognosis characterized by the absence of each of these features

Investigations (for Staging)

- blood work: CBC, electrolytes, creatinine, β-hCG, TSH, LFTs
- imaging: CXR, U/S pelvis only
- if CXR shows lung metastasis then CT abdomen/pelvis, MRI brain
- if suspect brain metastasis but CT brain negative, consider lumbar puncture for CSF β-hCG
- ratio of plasma β-hCG:CSF β-hCG <60 indicates metastases

Lungs are the primary site for malignant GTN metastases; when pelvic exam and CXR are negative, metastases are uncommon

Table 33. FIGO Staging and Management of Malignant GTN

Stage	Findings	Management
I	Disease confined to uterine corpus	Single agent chemotherapy for low-risk disease (WHO score ≤6) 1st line: pulsed actinomycin D (Act-D) IV q2 wk Alternatives: methotrexate (MTX)-based regimen 20% of patients need to switch to alternate single-agent regimen due to failure of β-hCG to return to normal Combination chemotherapy (EMA-CO: etoposide, MTX, ACT-D, cyclophosphamide, vincristine) if high-risk (WHO score ≥7) or if resistant to single-agent chemotherapy Can consider hysterectomy if fertility not desired or placental-site trophoblastic tumour
II	Metastatic disease to genital structures	As above
III	Metastatic disease to lungs with or without genital tract involvement	As above
IV	Distant metastatic sites including brain, liver, kidney, GI tract	Ultra high-risk patients should have low-dose induction chemotherapy weekly for 1-3 wk, followed by multi-agent chemotherapy

Follow-up (for GTN)

- contraception for all stages to avoid pregnancy during entire follow-up period, recommended combined OCP
- stage I, II, III
  - weekly β-hCG until 3 consecutive normal results
  - then monthly x 6-12 mo
- stage IV
  - weekly β-hCG until 3 consecutive normal results
  - then monthly x 24 mo

Common Medications

Table 34. Common Medications

Drug Name (Brand Name)	Action	Dosing Schedule	Indications	Side Effects (S/E), Contraindications (C/I), Drug Interactions (D/I)
acyclovir (Zovirax®)	Antiviral; inhibits DNA synthesis and viral replication	**First Episode**: 400 mg PO TID x 7-10 d **Recurrence**: 400 mg PO TID x 5 d	Genital herpes	**S/E**: headache, GI upset **D/I**: zidovudine, probenecid
bromocriptine (Parlodel®)	Dopaminomimetic, agonist at D2 Receptor and antagonist at D1 Receptor; acts directly on anterior pituitary cells to inhibit synthesis and release of prolactin	**Initial**: 1.25-2.5 mg PO once daily at night with food **Then**: increase by 2.5 mg every 2-7 d as needed until optimal therapeutic response **Usual Range**: 1.5-15 mg once daily For IVF: **Initial**: 1.25 mg/d PO between days 4-6 of follicular phase **Then**: 2.5 mg/d until 3 d after onset menstruation	Galactorrhea + amenorrhea 2° to hyperprolactinemia Prolactin-dependent menstrual disorders and infertility Prolactin-secreting adenomas (microadenomas, prior to surgery of macroadenomas) IVF	**S/E**: N/V, headache, postural hypotension, somnolence **C/I**: uncontrolled HTN, pregnancy-induced HTN, CAD, breastfeeding **D/I**: domperidone, macrolides, octreotide
clomiphene citrate (Clomid®)	Increases output of pituitary gonadotropins to induce ovulation	50 mg once daily x 5 d Try 100 mg or 160 mg once daily If ineffective 3 courses: adequate trial	Patients with persistent ovulatory dysfunction (e.g. amenorrhea, PCOS) who desire pregnancy	**S/E**: Common: hot flashes, abdominal discomfort, exaggerated cyclic ovarian enlargement, accentuation of Mittelschmerz Rare: ovarian hyperstimulation syndrome, multiple pregnancy, visual blurring, birth defects **C/I**: pregnancy, liver disease, hormone-dependent tumours, ovarian cyst, undiagnosed vaginal bleeding
clotrimazole (Canesten®)	Antifungal; disrupts fungal cell membrane	**Tablet**: 100 mg/d intravaginally x 7 d or 200 mg/d x 3 d or 500 mg x 1 dose **Cream** (1 or 2%): 1 applicator intravaginally QHS x 3-7 d **Topical**: apply BID x 7 d	Vulvovaginal candidiasis	**S/E**: vulvar/vaginal burning
combined oral contraceptive pill (OCP)	Ovulatory suppression by inhibiting LH and FSH Decidualization of endometrium Thickening of cervical mucus to prevent sperm penetration		Contraception Disorders of menstruation	See Tables 7-10, *GY15* and Table 12, *GY19*
dienogest (Visanne®)	Synthetic progestin	2 mg PO	Pelvic pain associated with endometriosis	**S/E**: changes to menstrual pattern, VTE **C/I**: pregnancy, lactation, liver disease/ malignancy, VTE disorders, cardiovascular disease, hormone-dependent tumours, undiagnosed AUB
doxycycline	Tetracycline derivative; inhibit protein synthesis	100 mg PO BID x ≥7 d	Chlamydia, gonococcal infection, syphilis	**S/E**: GI upset, hepatotoxicity **C/I**: pregnancy, severe hepatic dysfunction **D/I**: warfarin, digoxin
elagolix (Orlissa®)	Synthetic GnRH antagonist; induces reversible hypoestrogenic state	150 mg PO daily or 400 mg PO BID	Endometriosis, emerging evidence for fibroids, adenomyosis	**S/E**: hot flushing, nausea, headache **C/I**: pregnancy, osteoporosis, undiagnosed vaginal bleeding, severe hepatic dysfunction **D/I**: Organic Anion Transport Protein (OATP) 1B1 inhibitors
fluconazole (Diflucan®)	Antifungal; disrupt fungal cell membrane	150 mg PO x 1 dose	Vulvovaginal candidiasis unresponsive to clotrimazole	**S/E**: headache, rash, N/V, abdominal pain, diarrhea **D/I**: terfenadine, cisapride, astemizole, hydrochlorothiazide, phenytoin, warfarin, rifampin
intrauterine device (IUD) **copper IUD (Nova-T®)** **progesterone-releasing IUD (Mirena®, Kyleena®)**	Copper IUD: mild foreign body reaction in endometrium, which is toxic to sperm and alters sperm motility Progesterone-releasing IUD: decidualization of endometrium and thickening of cervical mucus, may suppress ovulation	Contraceptive effects last 3 yr; up to 5 yr (Copper IUD, Mirena®, Kyleena®)	Contraception Disorders of menstruation	See Tables 7-10, *GY15* and Table 12, *GY19*
leuprolide (Lupron®)	Synthetic GnRH antagonist; induces reversible hypoestrogenic state	3.75 mg IM q1 mo or 11.25 mg IM q3 mo Usually ≤6 mo, check bone density if >6 mo Retreatment with Lupron® alone not recommended because of effects on bone density	Endometriosis Leiomyomata DUB Precocious puberty	**S/E**: hot flashes, sweats, headache, vaginitis, reduction in bone density, acne, GI upset **C/I**: pregnancy, undiagnosed vaginal bleeding, breastfeeding

Table 34. Common Medications

Drug Name (Brand Name)	Action	Dosing Schedule	Indications	Side Effects (S/E), Contraindications (C/I), Drug Interactions (D/I)
menotropin (Pergonal®)	Human gonadotropin with FSH and LH effects; induce ovulation and stimulate ovarian follicle development	75-150 IU of FSH and LH IM once daily x 7-12 d, then 10000 IU HCG 1 d after last dose	Infertility	**S/E**: bloating, irritation at injection site, abdominal/pelvic pain, headache, N/V, multiple pregnancy **C/I**: primary ovarian failure, intracranial lesion (e.g. pituitary tumour), uncontrolled thyroid/adrenal dysfunction, ovarian cyst (not PCOS), pregnancy, undiagnosed uterine bleeding
metronidazole (Flagyl®)	Bactericidal; forms toxic metabolites which damage bacterial DNA	2 g PO x 1 dose or 500 mg PO BID x 7 d	Bacterial vaginosis, trichomonas vaginitis	**S/E**: headache, dizziness, N/V, diarrhea, disulfiram-like reaction (flushing, tachycardia, N/V) **C/I**: pregnancy (1st trimester) **D/I**: cisapride, warfarin, cimetidine, lithium, alcohol, amiodarone, milk thistle, carbamazepine
nexplanon (etonogestrel implant)	Releases progestin which causes decidualization of endometrium and thickening of cervical mucus, may suppress ovulation	Contraceptive effects last up to 3 yr	Contraception Disorders of menstruation	See Tables 7-10, *GY15* and Table 12, *GY19*
oxybutynin (Ditropan®)	Anticholinergic; relaxes bladder smooth muscle, inhibits involuntary detrusor contraction	5 or 10 mg/d PO May increase doses by 5 mg weekly to a max of 30 mg/d	Overactive bladder (urge incontinence)	**S/E**: dry mouth/eyes, constipation, palpitations, urinary retention, dizziness, headache **C/I**: glaucoma, GI ileus, severe colitis, obstructive uropathy, use with caution if impaired hepatic/renal function
tolterodine (Detrol®)	Anticholinergic	1-2 mg PO BID	Overactive bladder (urge incontinence)	**S/E**: anaphylaxis, psychosis, tachycardia, dry mouth/eyes, headache, constipation, urinary retention, chest pain, abdominal pain **C/I**: glaucoma, gastric/urinary retention, use with caution if impaired hepatic/renal function
tranexamic acid (Cyklokapron®)	Anti-fibrinolytic; reversibly inhibits plasminogen activation	1-1.5 g TID-QID for first 4 d of cycle Max 4 g/d Ophthalmic check if used for several wk	Menorrhagia	**S/E**: N/V, diarrhea, dizziness, rare cases of thrombosis, abdominal pain, MSK pain **C/I**: thromboembolic disease, acquired disturbances of colour vision, subarachnoid hemorrhage, age <15 yr
ulipristal acetate (Fibristal®) -withdrawn from market in 2020 urofollitropin (Metrodin®)	Selective progesterone receptor modulator (SPRM)	5 mg PO once daily for max 3 mo; first tablet taken anytime during first 7 d of menstruation	Leiomyoma (preoperative)	**S/E**: headache, hot flushes, constipation, vertigo, endometrial thickening **C/I**: pregnancy, undiagnosed vaginal bleeding, any gynecological cancer
urofollitropin (Metrodin®)	FSH	75 IU/d SC x 7-12 d	Ovulation induction in PCOS	**S/E**: ovarian enlargement or cysts, edema and pain at injection site, arterial thromboembolism, fever, abdominal pain, headache, multiple pregnancy **C/I**: primary ovarian failure, intracranial lesion (e.g. pituitary tumour), uncontrolled thyroid/adrenal dysfunction, ovarian cyst (not PCOS), pregnancy, abnormal uterine bleeding

Landmark Gynecology Trials

Trial Name	Reference	Clinical Trial Details
Endometrial Cancer		
PORTEC-3	LANCET 2019; 20(9):1273-1285	**Title**: Adjuvant Chemoradiotherapy versus Radiotherapy Alone in Women with High-Risk Endometrial Cancer (PORTEC-3): Patterns of Recurrence and Post-Hoc Survival Analysis of a Randomised Phase 3 Trial **Purpose**: To investigate the benefit of combined adjuvant chemotherapy and radiotherapy vs. pelvic radiotherapy alone for women with high-risk endometrial cancer. **Methods**: Women with high-risk endometrial cancer were randomly assigned to receive radiotherapy alone or chemoradiotherapy. The co-primary endpoints were overall survival and failure-free survival. Secondary endpoints included vaginal, pelvic, and distance recurrence. **Results**: At a median of 72.6 mo, 5 yr overall survival was 81.4% with chemoradiotherapy vs. 76.1% with radiotherapy, and 5 yr failure-free survival was 76.5% with chemoradiotherapy vs. 69.1% with radiotherapy. Distant metastases occurred in 78/330 women in the chemoradiotherapy group vs. 98/330 in the radiotherapy group. **Conclusions**: For women with stage 3 or serous endometrial cancers, or both, chemoradiotherapy should be recommended over radiotherapy alone.
Cervical Cancer		
LACC	NEJM 2018; 379:1895-1904	**Title**: Minimally Invasive versus Abdominal Radical Hysterectomy for Cervical Cancer **Purpose**: To investigate survival outcomes after laparoscopic or robot-assisted radical hysterectomy (minimally invasive surgery) vs. open abdominal radical hysterectomy (open surgery). **Methods**: Patients with stage A1, IA2, or IB1 cervical cancer and a histologic subtype of squamous-cell carcinoma, adenocarcinoma, or adenosquamous carcinoma, were randomly assigned to undergo minimally invasive surgery or open surgery. **Results**: The rate of disease-free survival at 4.5 yr was 86% with minimally invasive surgery and 96.5% with open surgery, a difference of -10.6% (95% confidence interval [CI], −16.4 to −4.7). Minimally invasive surgery was associated with a lower rate of disease-free survival than open surgery (3 yr rate, 91.2% vs. 97.1%) and a lower rate of overall survival (3 yr rate, 93.8% vs. 99.0%). **Conclusions**: Among women with early-stage cervical cancer, minimally invasive radical hysterectomy was associated with lower rates of disease-free survival and overall survival than open abdominal radical hysterectomy.
Concurrent chemotherapy and pelvic radiation therapy compared with pelvic radiation therapy alone as adjuvant therapy after radical surgery in high-risk early-stage cancer of the cervix	J Clin Oncology 2000; 18(8):1606-1613	**Title**: Concurrent chemotherapy and pelvic radiation therapy compared with pelvic radiation alone as adjuvant therapy after radical surgery in high-risk early-stage cancer of the cervix **Purpose**: Determine whether adjuvant cisplatin-based chemotherapy (CT) in addition to pelvic radiation therapy (RT) has benefit for early stage, high risk cervical cancer. **Methods**: In this multi-center trial, patients with stage IA2, IB, and IIA cervical cancer treated with radical hysterectomy and pelvic lymphadenectomy, with high-risk prognostic factors on surgical sample were randomized to CT+RT (n=127) and RT (n=116). Primary outcomes were progression free and overall survival. **Results**: 4-year progression free survival was 80% in the CT-RT group and 63% in the CT group. CT-RT improved both progression-free survival (HR, 2.01; p = 0.003) and overall survival (HR, 1.96; p = 0.007). **Conclusions**: CT+RT adjuvant therapy following radical surgery improved survival for high-risk, early-stage cervical cancer.
Ovarian Cancer		
LION	NEJM 2019; 380:822-832	**Title**: A Randomized Trial of Lymphadenectomy in Patients with Advanced Ovarian Neoplasms **Purpose**: Clarify role for pelvic and para-aortic lymphadenectomy in surgical treatment of patients with advanced ovarian cancer. **Methods**: In this international, multi-center trial, patients with advanced epithelial ovarian cancer who underwent macroscopically complete resection and had negative lymph nodes before and during surgery, were randomized to lymphadenectomy (n=323) or no lymphadenectomy (n=324). The primary outcome was overall survival. **Results**: Median overall survival was 65.5 mo in the lymphadenectomy and 69.2 mo in the no lymphadenectomy (HR, 1.06; 95% CI, 0.83-1.34; p = 0.65). Incidence of repeat laparotomy was higher in the lymphadenectomy at 12.4% compared to 6.5% in the no lymphadenectomy group (p = 0.01). **Conclusions**: Pelvic and para-aortic lymphadenectomy in surgically treated advanced ovarian cancer was not associated with longer overall survival and increased risk of complications.

Thrombocytosis
Pancytopenia
Neutrophilia
Neutropenia
Lymphocytosis
Lymphopenia
Eosinophilia
Agranulocytosis
Leukemoid Reaction

Approach to Lymphadenopathy H12

Approach to Splenomegaly H13

Microcytic Anemia H14
Iron Metabolism
Iron Deficiency Anemia
Anemia of Chronic Disease
Sideroblastic Anemia
Lead Poisoning

Normocytic Anemia H17
Aplastic Anemia

Hemolytic Anemia H18
Thalassemia
β-Thalassemia Minor (Thalassemia Trait)
β-Thalassemia Major
β-Thalassemia Intermedia
α-Thalassemia
Sickle Cell Disease
Autoimmune Hemolytic Anemia
Microangiopathic Hemolytic Anemia (MAHA)/Thrombotic Microangiopathy (TMA)
Hereditary Spherocytosis
Hereditary Elliptocytosis
Glucose-6-Phosphate Dehydrogenase Deficiency

Macrocytic Anemia H25
Vitamin B_{12} Deficiency
Folate Deficiency

Hemostasis H26
Stages of Hemostasis

Disorders of Primary Hemostasis H28
Immune Thrombocytopenia
Thrombotic Microangiopathies (TMAs)
von Willebrand Disease

Disorders of Secondary Hemostasis/Fibrinolysis H32
Hemophilia A (Factor VIII Deficiency)
Hemophilia B (Factor IX Deficiency)
Factor XI Deficiency
Liver Disease
Vitamin K Deficiency
Disseminated Intravascular Coagulation

Hypercoagulable Disorders H35

Venous Thromboembolism H36
Approach to Treatment of Venous Thromboembolism

Hematologic Malignancies and Related Disorders H39

Myeloid Malignancies H39
Acute Myeloid Leukemia
Myelodysplastic Syndromes

Myeloproliferative Neoplasms H42
Chronic Myeloid Leukemia
Polycythemia Vera
Idiopathic Myelofibrosis
Essential Thrombocythemia

Lymphoid Malignancies H46
Acute Lymphoblastic Leukemia

Lymphomas H47
Hodgkin Lymphoma
Non-Hodgkin Lymphoma

Malignant Clonal Proliferations of Mature B-Cells H50
Chronic Lymphocytic Leukemia
Multiple Myeloma
Monoclonal Gammopathy of Unknown Significance
Lymphoplasmacytic Lymphoma

Complications of Hematologic Malignancies H53
Hyperviscosity Syndrome
Tumour Lysis Syndrome

Blood Products and Transfusions H54
Blood Products
Red Blood Cells
Platelets
Coagulation Factors
Acute Blood Transfusion Reactions
Delayed Blood Transfusion Reactions

Common Medications H58
Antiplatelet Therapy
Anticoagulant Therapy

Acronyms

Ab	antibody
AFib	atrial fibrillation
AFLP	acute fatty liver of pregnancy
aHUS	atypical hemolytic uremic syndrome
AIHA	autoimmune hemolytic anemia
ALL	acute lymphoblastic leukemia
AML	acute myeloid leukemia
ANC	absolute neutrophil count
APC	activated protein C
APL	acute promyelocytic leukemia
APLA	antiphospholipid antibodies
APS	antiphospholipid antibody syndrome
aPTT	activated partial thromboplastin time
ARDS	acute respiratory distress syndrome
ATIII	antithrombin III
ATRA	all-trans retinoic acid
BM	bone marrow
CALR	calreticulin
CAR	chimeric antigen receptor
CLL	chronic lymphocytic leukemia
CML	chronic myeloid leukemia
CMV	cytomegalovirus
CRP	C-reactive protein
DAT	direct antiglobulin test
DDAVP®	desmopressin
DIC	disseminated intravascular coagulation
DLBCL	diffuse large B-cell lymphoma
DOAC	direct oral anticoagulant
DVT	deep vein thrombosis
EBV	Epstein-Barr virus
EDTA	ethylenediaminetetraacetic acid
EPO	erythropoietin
ESA	erythropoiesis-stimulating agent
ESR	erythrocyte sedimentation rate
ET	essential thrombocythemia
FDP	fibrin degradation products
FNA	fine needle aspiration
FP	frozen plasma
G-CSF	granulocyte-colony stimulating factor
GSH	reduced glutathione
GU	genitourinary
GVHD	graft versus host disease
HA	hemolytic anemia
Hb	hemoglobin
HBV	hepatitis B virus
Hct	hematocrit
HCV	hepatitis C virus
HELLP	hemolysis, elevated liver enzymes, and low platelet count
HIT	heparin-induced thrombocytopenia
HL	Hodgkin lymphoma
HMWK	high molecular weight kininogen
HUS	hemolytic uremic syndrome
IBD	inflammatory bowel disease
IMF	idiopathic myelofibrosis
IMID	immunomodulatory drugs
INR	international normalized ratio
IPC	intermittent pneumatic compression
IPSS	international prognostic scoring system
ITP	immune thrombocytopenia
JAK2	Janus kinase 2
LAD	lymphadenopathy
LMWH	low molecular weight heparin
MAHA/TMA	microangiopathic hemolytic anemia/thrombotic microangiopathy
MCH	mean corpuscular Hb
MCHC	mean corpuscular Hb concentration
MCV	mean corpuscular volume
MDS	myelodysplastic syndromes
MF	myelofibrosis
MGUS	monoclonal gammopathy of unknown significance
MM	multiple myeloma
MPN	myeloproliferative neoplasm
MPV	mean platelet volume
MUGA	multi-gated acquisition
NHL	non-Hodgkin lymphoma
OCP	oral contraceptive pill
PCC	prothrombin complex concentrates
PE	pulmonary embolism
PFS	progression-free survival
Ph	Philadelphia chromosome
PI	proteasome inhibitors
PK	prekallikrein
PMN	polymorphonuclear neutrophil
PNH	paroxysmal nocturnal hemoglobinuria
PT	prothrombin time
PTT	partial thromboplastin time
PUD	peptic ulcer disease
PV	polycythemia vera
RCMD	refractory cytopenia with multilineage dysplasia
RCMD-RS	refractory cytopenia with multilineage dysplasia and ringed sideroblasts
RDW	RBC distribution width
SCD	sickle cell disease
SCT	stem cell transplantation
SPEP	serum protein electrophoresis
sTfR	soluble transferrin receptor
TCL	T-cell lymphoma
TIBC	total iron binding capacity
TKI	tyrosine kinase inhibitor
T-LGL	T-cell large granular lymphocyte
TLS	tumour lysis syndrome
tPA	tissue plasminogen activator
TPO	thrombopoietin
TT	thrombin time
TTP	thrombotic thrombocytopenic purpura
UFH	unfractionated heparin
UPEP	urine protein electrophoresis
VTE	venous thromboembolism
VWD	von Willebrand disease
VWF	von Willebrand factor
WHO	World Health Organization
XRT	radiation therapy

Basics of Hematology

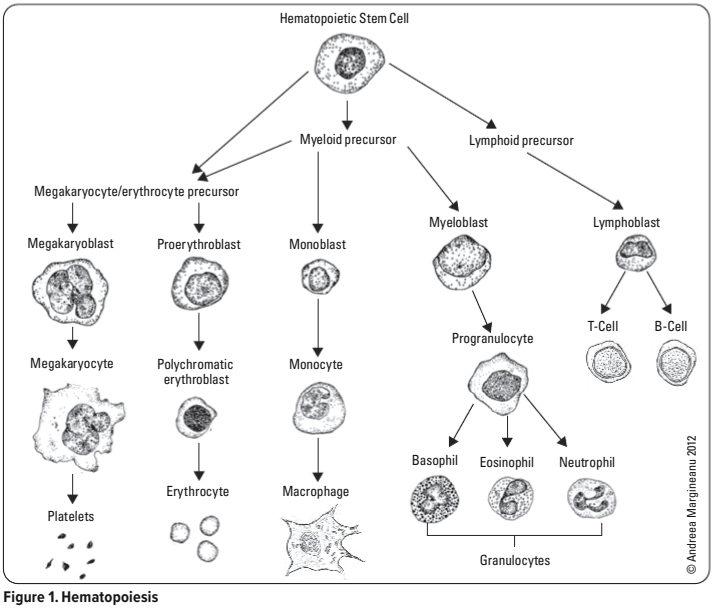

Figure 1. Hematopoiesis

Erythrocyte: carries oxygen from lungs to peripheral tissues
Reticulocyte: immature erythrocyte
Hb: protein contained in erythrocytes which binds oxygen
Neutrophil: granulocyte integral in innate immunity; main cell in acute inflammation
Eosinophil: granulocyte involved in response to parasites (especially helminths) and allergic response
Basophil: granulocyte mainly involved in allergy and parasitic infection
Lymphocyte: integral cell in adaptive immunity
Monocyte: involved in innate immunity; can differentiate into macrophage or dendritic cell
Platelet: mediator of primary hemostasis
Plasma: acellular, fluid component of blood containing water and proteins (including coagulation factors and immunoglobulins)
Serum: equivalent to plasma minus coagulation factors

- over 10 [11]blood cells are produced daily
- sites of hematopoiesis in adults: pelvis, sternum, vertebral bodies, and cranium
- lifespan of mature cells in blood
  - erythrocytes (90-120 d), neutrophils (~1 d), platelets (7-10 d), lymphocytes (varies – memory cells persist for years)

- role of lymphoid organs
  - spleen - part of reticuloendothelial system: sequesters aged RBCs, removes opsonized cells, and site of Ab production
  - thymus - involutes with age: site of T-cell maturation
  - lymph nodes: sites of B- and T-cell activation (adaptive immune response)

Complete Blood Count

Table 1. Common Terms Found in the CBC

Test	Definition	Normal Values*
RBC Count	Number of RBCs per volume of blood	3.5-5.0 x 10^{12}/L (female) 4.0-5.5 x 10^{12}/L (male)
Hb	Amount of Hb in the blood	115-155 g/L (female) 125-170 g/L (male)
Hct	Percentage of a given volume of whole blood occupied by packed RBCs	38-50%
MCV	Average RBC size	80-100 fL
MCH	Average amount of Hb per RBCs	25-34 pg (female) 27-34 pg (male)
MCHC	Average concentration of Hb inside RBCs	315-355 g/L
RDW	Percentage of variance in RBC size	11.5-15.5%
Reticulocyte Count	Number of reticulocytes per volume of blood	23-90 x 10^9/L (0.5-1.5%)
ESR	Rate at which RBCs separate from the serum, becoming sediment in the bottom of the test tube	<20 mm/h (female) <10 mm/h (male)
WBC Count	Number of WBCs per volume of blood	3.5-10.5 x 10^9/L
WBC Differential	Segmented neutrophils Band neutrophils Basophils Eosinophils Lymphocytes Monocytes	2-7 x 10v/L <0.7 x 10^9 /L <0.10 x 10^9/L <0.5 x 10^9/L 0.8-3.3 x 10^9/L (female) 0.8-3.5 x 10^9/L (male)L 0.1-1.0 x 10^9/L
Platelet Count	Number of platelets per volume of blood	130-380 x 10^9/L
Mean Platelet Volume (MPV)	Measurement of platelet size	9.0-14.0 fL

*All values apply to adults. Reference standards do not apply to all ethnic groups.

To estimate Hb based on the Hct, multiply by 3

Approach to Interpreting a CBC

1. consider values in the context of an individual's baseline:
   - up to 5% of population without disease may have values outside "normal" range
   - an individual may display a clinically significant change from their baseline without violating "normal" reference range
2. is one cell line affected or are several?
   - if all lines are low: pancytopenia (see *Pancytopenia, H8*)
   - if RBCs and platelets are low: consider a MAHA/TMA (see *Microangiopathic Hemolytic Anemia/ Thrombotic Microangiopathy, H23*) or an autoimmune process (Evan's Syndrome)
   - if single cell line affected: see *Common Presenting Problems, H6*

Clinical Use of RDW
To distinguish the etiologies of microcytosis:
Iron deficiency: increased RDW (anisocytosis) as cells are of varying sizes in iron deficiency
β-thalassemia minor: normal RDW (also expect a high RBC count) as cells are of similar size because the red cell abnormality is not progressive

Blood Film Interpretation

RED BLOOD CELLS

Size

- microcytic (MCV <80 fL), normocytic (MCV = 80-100 fL), macrocytic (MCV >100 fL)
- anisocytosis: RBCs with increased variability in size (increased RDW)
  - iron deficiency anemia, HAs, MF, blood transfusion, and MDS

Colour

- hypochromic: increase in size of central pallor (normal = less than 1/3 of RBC diameter)
  - iron deficiency anemia, anemia of chronic disease, and sideroblastic anemia
- polychromasia: suggests increased reticulocytes (pinkish-blue cells)
  - increased RBC production by BM

Shape

- poikilocytosis: increased proportion of RBCs of abnormal shape
  - iron deficiency anemia, hemoglobinopathies, MF, severe B_{12} deficiency, MDS, and burns

Table 2. Common Erythrocyte Shapes

Shape	Definition	Associated Conditions
Discocyte	Biconcave disc	Normal RBC
Spherocyte	Spheroidal RBC (due to membrane defect or loss of membrane) Loss of central pallor	Hereditary spherocytosis, immune hemolytic anemia
Elliptocyte/Ovalocyte	Oval-shaped, elongated RBCs • Elliptocytes: the RBC long axis is ≥2x the length of the short axis • Ovalocytes: the RBC long axis is <2x the length of the short axis	Hereditary elliptocytosis, megaloblastic anemia, MF, iron-deficiency anemia (pencil forms), and MDS
Schistocyte (helmet cell, fragment)	Fragmented cells (due to traumatic disruption of membrane)	MAHA/TMA (HUS, aHUS, TTP, DIC, preeclampsia, HELLP, malignant HTN), vasculitis, glomerulonephritis, burns, and prosthetic heart valves
Sickle Cell	Sickle-shaped RBC (due to polymerization of HbS)	Sickle cell disorders: HbSC, HbSS
Codocyte (target cell)	"Bull's eye" (due to a surface that is disproportionately large compared to their volume)	Liver disease, HbSC, thalassemia, iron deficiency anemia, and asplenia
Dacrocyte (teardrop cell)	Single pointed end, looks like a teardrop	MF, MDS, β-thalassemia, megaloblastic anemia, and BM infiltration
Acanthocyte (spur cell)	Distorted RBC with irregularly distributed thorn-like projections (due to abnormal membrane lipid or protein composition)	Severe liver disease (spur cell anemia), starvation/anorexia, and post-splenectomy
Echinocyte (burr cell)	RBC with numerous regularly spaced, small, spiny projections	Uremia, HUS, burns, cardiopulmonary bypass, post-transfusion, and storage artifact
Rouleaux Formation	Aggregates of RBCs resembling stacks of coins (due to increased plasma concentration of high molecular weight proteins)	Pregnancy is most common cause (due to physiological increase in fibrinogen), inflammatory conditions (due to polyclonal immunoglobulins), plasma cell dyscrasias (due to monoclonal paraproteinemia, e.g. MM, macroglobulinemia), and storage artifact

Illustrations: Ayalah Hutchins and Merry Shiyu Wang 2012

Table 3. RBC Inclusions

Inclusions	Definition	Associated Conditions
Nucleus	Present in erythroblasts (immature RBCs)	Hyperplastic erythropoiesis (seen in hypoxia, hemolytic anemia), BM infiltration disorders, and MPNs (MF)
Heinz Bodies	Denatured and precipitated Hb	G6PD deficiency (post-exposure to oxidant), thalassemia, and unstable Hb
Howell-Jolly Bodies	Small spherical nuclear remnant, typically in periphery and ordinarily removed by the spleen	Post-splenectomy, hyposplenism (SCD), neonates, and megaloblastic anemia
Basophilic Stippling	Deep blue granulations indicating ribosome aggregation	Thalassemia, heavy metal (Pb, Zn, Ag, Hg) poisoning, megaloblastic anemia, MDS, and hereditary (pyrimidine 5'-nucleotidase deficiency)
Sideroblasts	Late erythrocytes in BM with Fe-containing granules in the cytoplasm	Hereditary, idiopathic, drugs, ethanol, hypothyroidism (see *Sideroblastic Anemia, H17*), MDS, and toxins (Pb)

Illustrations: Ayalah Hutchins and Merry Shiyu Wang 2012

WHITE BLOOD CELLS

lymphocytes
- comprise 30-40% of WBCs; great variation in "normal" lymphocyte morphology
- the major classes of lymphocytes include: T cells, B cells, and natural killer (NK) cells
- nucleus occupies ~90% of cytoplasm

- neutrophils
  - normally, only mature neutrophils (with 3-4 lobed nuclei) and band neutrophils (immediate precursor with horseshoe-shaped nuclei) are found in circulation
  - hypersegmented neutrophil: >5 lobes suggests megaloblastic process (B_{12} or folate deficiency)
  - left shift (increased granulocyte precursors)
    - seen in leukemoid reactions: acute infections, pregnancy, neonates, hypoxia, shock, MPNs (CML, MF), and G-CSF (growth factor that stimulates neutrophil production) use
- blasts
  - immature, undifferentiated precursors; associated with acute leukemia, MDS, and G-CSF use

Table 4. Abnormal WBC on Film

Appearance	Definition	Associated Conditions
Smudge Cell	Lymphocytes damaged during blood film preparation indicating cell fragility	CLL and other lymphoproliferative disorders
Auer Rod	Cytoplasmic inclusions that form long needles in the cytoplasm of myeloblasts	Pathognomonic for AML
Atypical Lymphocyte	Pale blue cytoplasm with pink granules. Cytoplasm is indented by RBC edges	Viruses (particularly EBV) and T-LGL leukemia

Illustrations: Ayalah Hutchins and Merry Shiyu Wang 2012 and Danielle Sayeau 2017

Left Shift

Refers to an increase in granulocyte precursors in the peripheral blood film (myelocytes, metamyelocytes, promyelocytes, blasts). If present, implies increased marrow production of granulocytes (e.g. inflammation, infection, G-CSF administration, CML)

The presence of predominantly blasts in the peripheral smear without further differentiated precursor cells or mature neutrophils, suggests clonal cell disorder (MDS, acute leukemias)

If >20% of the total WBC differential consists of blasts, this is acute leukemia and is a medical emergency

PLATELETS

- small, purple, anuclear cell fragments

Bone Marrow Aspiration and Biopsy

- sites: posterior iliac crest/spine, sternum (aspiration only)
- analyses: most often done together
  - aspiration: takes a fluid marrow sample for cellular morphology (includes iron stain), flow cytometry, cytogenetics, molecular studies, and microbiology (C&S, acid-fast bacilli smear and culture, and PCR)
    - note: differential diagnosis for a "dry tap": MF, hairy cell leukemia, BM infiltration
  - biopsy: takes a sample of intact BM to assess histology (architecture) and immunohistochemistry
  - only aspirates, not biopsies, can be obtained from the sternal site

Indications

- unexplained CBC abnormalities
- diagnosis and evaluation of infiltrating cancers: plasma cell disorders, leukemias, and solid tumours
- diagnosis and staging of lymphoma or solid tumours
- evaluate iron metabolism and stores (gold standard, but rarely done)
- evaluate suspected deposition and storage disease (e.g. amyloidosis, Gaucher's disease)
- evaluate fever of unknown origin, suspected mycobacterial, fungal, and parasitic infections, or granulomatous disease
- evaluate unexplained splenomegaly
- confirm normal BM in potential allogeneic hematopoietic cell donor

Important Considerations

- do not perform a BM biopsy if there is evidence of infection over the targeted skin site
- risk of procedure: 1/100 chance of bleeding, very rare infection risk

Common Presenting Problems

Anemia

Definition

- a decrease in RBC mass that can be detected by Hb concentration, Hct, and RBC count
  - adult males: Hb <130 g/L or Hct <38%
  - adult females: Hb <120 g/L or Hct <37% (changes with pregnancy and trimester)

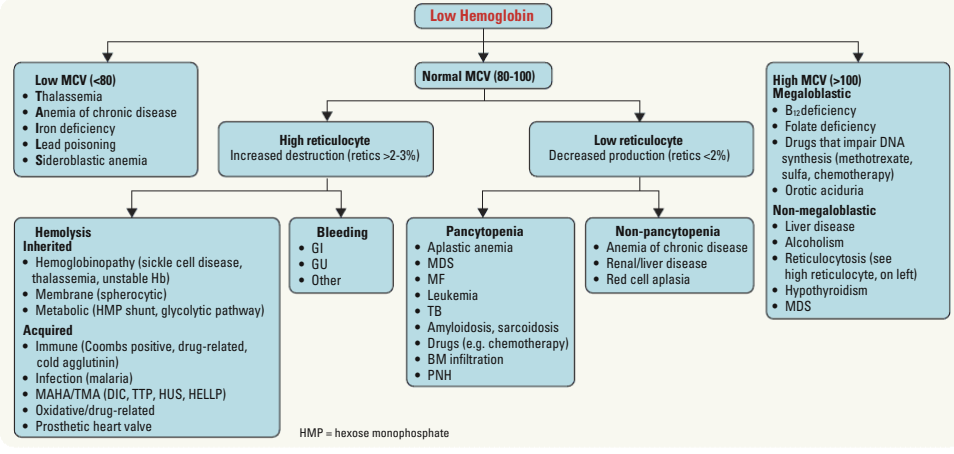

Figure 2. Approach to anemia – classification by MCV

Clinical Features

- history
  - symptoms of anemia: fatigue, headache, light-headedness, malaise, weakness, decreased exercise tolerance, dyspnea, palpitations, dizziness, tinnitus, and syncope
  - acute vs. chronic, bleeding, systemic illness, travel, medications, diet (Fe, B_{12} sources), alcohol, and family history
  - symptoms of hemolysis: jaundice, icterus
  - menstrual history: menorrhagia, menometrorrhagia
  - rule out pancytopenia (recurrent infection, mucosal bleeding, and easy bruising)
- physical signs
  - HEENT: pallor in mucous membranes and conjunctiva at Hb <90 g/L, ocular bruits at Hb <55 g/L, angular cheilitis, and jaundice
  - cardiac: tachycardia, orthostatic hypotension, systolic flow murmur, wide pulse pressure, and signs of CHF
  - dermatologic: ecchymosis, petechiae, pallor in palmar skin creases at Hb <75 g/L, jaundice (if due to hemolysis), nail changes (spooning), and glossitis
  - splenomegaly, lymphadenopathy

Reticulocytes

- Reticulocytes are immature erythrocytes and are markers of erythrocyte production (↑ colour, ↓ central pallor, ↑ size)
- The reticulocyte count should always be interpreted in the context of Hb concentration
- The reticulocyte count should normally increase in response to a decrease in RBC
- With blood loss, reticulocytes should increase 2-3x initially and then 5-7x over the next week
- A normal reticulocyte count in anemia should be interpreted as a sign of decreased production, and may result from BM infiltration, nutritional deficiency, or other causes
- Anemia with reticulocytosis suggests appropriate BM response

Investigations

- rule out dilutional anemia (low Hb due to increased effective circulating volume)
- CBC with differential, reticulocyte count, and blood film
- rule out nutritional deficit, gastrointestinal and genitourinary disease in iron deficiency anemia
- additional laboratory investigations as indicated (see *Microcytic Anemia, H14, Normocytic Anemia, H17, Hemolytic Anemia, H18,* and *Macrocytic Anemia, H25*)
- N.B. may have a mixed picture with multiple concomitant nutritional deficiencies

Treatment

- treat underlying cause (see *Microcytic Anemia, H14, Normocytic Anemia, H17, Hemolytic Anemia, H18,* and *Macrocytic Anemia, H25*)

Erythrocytosis

Definition

- an increase in Hb and/or Hct: Hb >165 g/L or Hct >49% (males); Hb >160 g/L or Hct >48% (females)

Etiology

- relative/spurious erythrocytosis (decreased plasma volume): diuretics, severe dehydration, burns, and "stress" (Gaisböck's syndrome)
- absolute erythrocytosis

Table 5. Etiology of Erythrocytosis

Primary	Secondary	Inappropriate Production of Erythropoietin
PV (see *Polycythemia Vera, H43*)	Physiologic (poor tissue oxygenation/hypoxia)	Tumours
	Carbon monoxide poisoning	Hepatocellular carcinoma
	Heavy smoking	Renal cell carcinoma
	High altitude	Cerebellar hemangioblastoma
	Pulmonary Disease	Pheochromocytoma
	COPD	Uterine leiomyoma
	Sleep apnea	Ovarian tumour
	Pulmonary hypertension	Other
	Cardiovascular Disease	Polycystic kidney disease
	R to L shunt (Eisenmenger syndrome)	Renal artery stenosis
	Hemoglobinopathy	Post-kidney transplant
	High O2 affinity Hb	Hydronephrosis
	Methemoglobinemia	Androgens
		Exogenous EPO
		SGLT2 inhibitors

Clinical Features

- secondary to high red cell mass and hyperviscosity
  - headache, dyspnea, dizziness, tinnitus, visual disturbances, hypertensive symptoms, and paresthesia
  - symptoms of angina, CHF, and aquagenic pruritus (only in MPNs)
- thrombosis (venous or arterial) or bleeding (seen with acquired VWD or acquired platelet dysfunction in MPNs)
- physical findings
  - splenomegaly ± hepatomegaly, facial plethora/ruddy complexion (70%) and/or palms, gout

Investigations

- serum EPO: differentiates primary (low/normal) from other etiologies (elevated)
  - search for tumour as source of EPO as indicated (e.g. abdominal U/S, CT head)
  - JAK-2 mutation analysis: positive in >96% of cases of PV
    - only send if low/normal EPO level
- ferritin (iron deficiency can mask the diagnosis; if iron deficient with reticulocytosis, suggestive of PV)

Treatment

- if primary: see *Polycythemia Vera, H43*
- if secondary: treat underlying cause
  - O2 for hypoxemia, CPAP for sleep apnea, surgery for EPO-secreting tumours, counselling and education (e.g. smoking cessation, work environment), use the lowest dose possible if on androgen therapy
  - often cardiologists will be hesitant to treat high Hct in cyanotic patients

Thrombocytopenia

Definition

- platelet count <150 x 10^9/L

Clinical Features

- history: mucocutaneous bleeding (easy bruising, gingival bleeding), epistaxis, perioperative bleeding (including dental procedures), heavy menstrual bleeding, peripartum bleeding, and GI bleeding
- physical exam: bruising, petechiae, ecchymoses, non-palpable purpura, and wet purpura
- see *Disorders of Primary Hemostasis, H28* for complications

Investigations

- CBC and differential
- blood film
  - rule out pseudothrombocytopenia (platelet clumping or platelet satellitism)
  - decreased production: other cell line abnormalities, blasts (suggesting myeloid malignancy), hypersegmented PMNs (suggesting megaloblastic anemia), and leukoerythroblastic changes (suggesting BM infiltration or fibrosis)
  - increased destruction: large platelets (often seen in ITP), schistocytes (seen in MAHA/TMA)
- workup for nutritional deficiencies: B12, RBC, folate
- PT/INR, aPTT, and fibrinogen if DIC suspected
- LFTs if findings of liver disease are present
- *H. pylori*, HIV, and HCV serology
- abdominal U/S to look for splenomegaly

Rule-of-thumb: a deficit in all cell lines suggests decreased production, sequestration, or hemodilution. A deficit in platelets and RBCs suggests non-immune destruction or Evan's syndrome. An isolated thrombocytopenia suggests an immune-mediated process. In hospitalized patients, drugs and infection account for the majority of cases of thrombocytopenia

Rule out pseudothrombocytopenia: platelet clumping secondary to EDTA Abs present in serum. This can be seen on blood film and confirmed by repeating in a citrated sample (i.e. using a sodium citrate tube to collect blood, rather than EDTA)

Wet vs. Dry Purpura
Wet purpura: hemorrhage of mucous membranes
Dry purpura: bruising or petechiae on skin surface

Treatments
- life-threatening bleeding: platelet transfusion (repeat CBC 1 h post-transfusion to confirm an appropriate rise in counts)
- if secondary: treat underlying cause
- ITP: see *Immune Thrombocytopenia, H28*

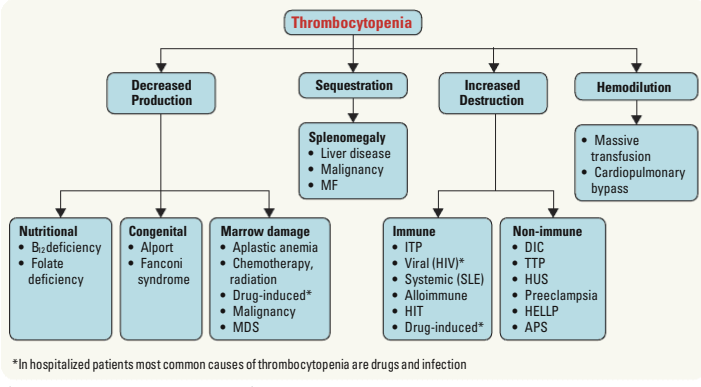

Figure 3. Approach to thrombocytopenia

Thrombocytosis

Definition
- platelet count >450 x 10^9/L
- primary thrombocytosis (uncommon): due to MPNs (e.g. CML, PV, primary MF, and ET; rarely associated with MDS)
- reactive/secondary thrombocytosis (common): acute phase reactant (e.g. surgery, inflammation, infection, trauma, bleeding, iron deficiency, neoplasm, ischemic injury, and hyposplenia/asplenia)

Clinical Features
- history: trauma, surgery, splenectomy, infection, inflammation, bleeding, iron deficiency, prior diagnosis of chronic hematologic disorder, and constitutional symptoms (malignancy)
- vasomotor symptoms: headache, visual disturbances, lightheadedness, atypical chest pain, acral dysesthesia, erythromelalgia, livedo reticularis, and aquagenic pruritus
- clotting risk, bleeding risk (rare)
- physical exam: splenomegaly is a common finding among patients with MPNs

Investigations
- CBC and differential, peripheral blood film, serum ferritin
- non-specific markers of infection or inflammation (e.g. CRP, ESR, ferritin)
- if reactive process has been ruled out, BM biopsy may be required to rule out MPN/MDS

Treatment
- primary: Aspirin™ ± cytoreductive agents (e.g. hydroxyurea, anagrelide, interferon-α)
- secondary: treat underlying cause

Pancytopenia

Definition
- a decrease in all hematopoietic cell lines below normal reference ranges

Clinical Features
- anemia: fatigue (see *Anemia, H6*)
- leukopenia: recurrent infections (see *Neutropenia, H9*)
- thrombocytopenia: mucocutaneous bleeding (see *Thrombocytopenia, H7*)

Investigations
- CBC and differential, peripheral blood film, serum ferritin, reticulocyte count, PT, PTT, blood type and screen, complete metabolic panel, B_{12}, folate
- non-specific markers of infection or inflammation (e.g. CRP, ESR, ferritin)
- workup as per *Figure 4, H9* and presenting symptoms/physical exam
- if reactive process has been ruled out, BM biopsy may be required

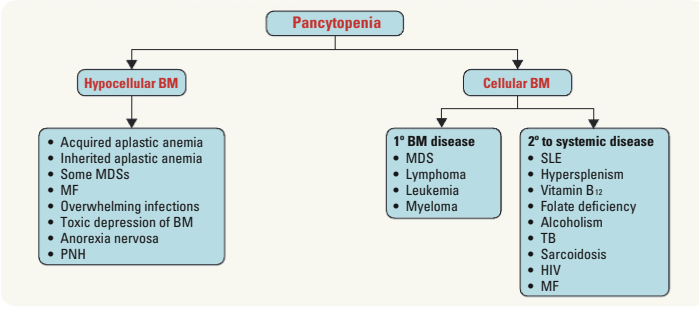

Figure 4. Approach to pancytopenia

Neutrophilia

Definition
- variable definition, but generally an ANC >7.7 x 10^9/L (WHO definition)

Etiology
- primary neutrophilia
  - CML, chronic neutrophilic leukemia
  - other MPNs: PV, ET, MF
  - hereditary neutrophilia (autosomal dominant)
  - chronic idiopathic neutrophilia in otherwise healthy patients
  - leukocyte adhesion deficiency
- secondary neutrophilia
  - stress/exercise/epinephrine: movement of neutrophils from marginated pool into circulating pool
  - obesity
  - infection
  - inflammation: e.g. rheumatoid arthritis (RA), IBD, chronic hepatitis, MI, PE, and burns
  - malignancy: hematologic (i.e. marrow invasion by tumour) and non-hematologic (especially large cell lung cancer)
  - medications: glucocorticoids, β-agonists, lithium, G-CSF

Clinical Features
- signs and symptoms of fever, inflammation, malignancy to determine appropriate further investigations
  - including LAD and organomegaly
- examine oral cavity, teeth, peri-rectal area, genitals, and skin for signs of infection

Investigations
- CBC and differential: mature neutrophils or bands >20% of total WBC suggests infection/inflammation
- blood film: left shifted WBCs, Döhle bodies (intracytoplasmic structures composed of agglutinated ribosomes), toxic granulation, and cytoplasmic vacuoles in infection
- may require BM biopsy if MPN suspected

Treatment
- directed at underlying cause

Neutropenia

Definition
- mild: ANC 1.0-1.5 x 10^9/L
- moderate: ANC 0.5-1.0 x 10^9/L (risk of infection starts to increase)
- severe: ANC <0.5 x 10^9/L
- profound: ANC <0.1 x 10^9/L for >7 d

ANC Calculation
ANC = WBC count x (%PMNs + %bands)
Beware of fever + ANC <0.5 x 10^9/L = FEBRILE NEUTROPENIA

Etiology

Table 6. Etiology of Neutropenia

Decreased Production	Peripheral Destruction/Sequestration	Excessive Margination (Transient Neutropenia)
Infection Viral hepatitis, EBV, HIV, TB, typhoid, malaria **Hematological Diseases** Idiopathic, aplastic anemia, MF, BM infiltration, cyclic, PNH, MDS, large granular lymphocyte leukemia, hairy cell leukemia, immune-mediated **Drug-Induced** Alkylating agents, antimetabolites, anticonvulsants, antipsychotics, anti-inflammatory agents, antithyroid drugs **Toxins/Chemicals** High dose radiation, benzene, dichloro diphenyl trichloroethane (DDT) **Nutritional Deficiency** B 12, folate **Idiopathic** Constitutional neutropenia, benign cyclic neutropenia	Anti-neutrophil Abs Spleen or lung trapping Autoimmune disorders: RA (Felty syndrome), SLE Granulomatosis with polyangiitis (formerly Wegener's) Drugs: haptens (e.g. α-methyldopa)	Idiopathic (most common) Overwhelming bacterial infection Hemodialysis Cardiopulmonary bypass Racial variation (e.g. African or Ashkenazi Jewish descent)

Prophylactic Hematopoietic Colony-Stimulating Factors on Mortality and Infection
Ann Intern Med 2007;147:400-411
Purpose: To review the effects of colony-stimulating factor (CSF) on mortality, infections, and febrile neutropenia in patients undergoing chemotherapy or SCT.
Study Selection: 148 RCTs comparing the effects of CSFs to either placebo or no therapy were included. Prophylactic CSFs were given concurrently with or after initiation of chemotherapy.
Results: There were no differences in all-cause mortality or infection-related death between CSF and placebo groups. Compared to placebo or no therapy, CSFs reduced infection rate (median rate 38.9% vs. 43.1%; rate ratio 0.85), microbiologically documented infections (MR 23.5% vs. 28.6%; rate ratio 0.86), and febrile neutropenia (MR 25.3% vs. 44.2%; rate ratio 0.71).
Conclusions: Prophylactic CSFs decrease infection rates and episodes of febrile neutropenia in patients undergoing chemotherapy or SCT, but have no effect on mortality.

Clinical Features
- fever, chills (only if infection present)
- infection by endogenous bacteria (e.g. *S. aureus*, Gram negatives from GI and GU tract)
- painful ulceration on skin, anus, mouth, and throat following colonization by opportunistic organisms
- avoid digital rectal exam

Investigations
- dependent on degree of neutropenia, history, and symptoms
- ranges from observation with frequent CBCs and differential with peripheral smears to BM aspiration and biopsy

Treatment
- manage specific underlying causes and medications that contribute to neutropenia
- regular dental care: chronic gingivitis and recurrent stomatitis are major sources of morbidity
- treatment of febrile neutropenia
- in severe immune-mediated neutropenia, G-CSF may increase neutrophil counts
  - if no response to G-CSF, consider immunosuppression (e.g. steroids, cyclosporine, and methotrexate)

G-CSF = Neupogen® = filgrastim

Lymphocytosis

Definition
- absolute lymphocyte count >4.0 x 10^9/L

Etiology
- infection (reactive lymphocytosis)
  - viral infections (majority); particularly mononucleosis
  - TB, pertussis, brucellosis, toxoplasmosis
- smoking
- physiologic response to stress (e.g. trauma, status epilepticus)
- hypersensitivity (e.g. drugs, serum sickness)
- autoimmune (e.g. RA)
- neoplasm (e.g. CLL, thymoma, B-cell lymphocytosis of undetermined significance)
- asplenia (e.g. post-splenectomy)

Presence of atypical lymphocytes suggests viral infection

Presence of smudge cells suggests a lymphoproliferative disorder if persistently elevated above 5.0 x 10^9/L for >3 mo; consider flow cytometry of peripheral blood

Investigations
- CBC and differential, peripheral smear assessing lymphocyte morphology, and in select cases, flow cytometry for assessing lineage and clonality

Treatment
- treat underlying cause

Lymphopenia

Definition
- absolute lymphocyte count <1.0 x 10^9/L

Etiology
- older age
- idiopathic CD4+ lymphopenia
- iatrogenic (radiation, chemotherapy, immunosuppressive agents)
- HIV/AIDS, HBV, HCV
- malignancy
- malnutrition, alcoholism
- autoimmune disease (e.g. SLE)

Clinical Features
- opportunistic infections (see Infectious Diseases, ID29)

Investigations
- CBC and differential, lymphocyte subpopulations, immunoglobulin levels

Treatment
- treat underlying cause
- treat opportunistic infections aggressively and consider antimicrobial prophylaxis (see Infectious Diseases, ID29)

Eosinophilia

Definition
- absolute eosinophil count >0.5 x 10^9/L

Etiology
- primary: due to clonal BM disorder
  - if no primary etiology identified, classified as hypereosinophilic syndrome (HES)
    - hypereosinophilia (absolute eosinophil count >1.5 x 10^9/L in the peripheral blood on 2 exams separated by ≥1 mo), with end-organ damage and no other identifiable cause
    - can involve heart, BM, and CNS
- secondary
  - most common causes are parasitic (usually helminth) infections and allergic reactions
  - less common causes:
    - collagen vascular diseases (e.g. RA, polyarteritis nodosa, see Rheumatology, RH8)
    - respiratory causes (asthma, eosinophilic pneumonia, and eosinophilic granulomatosis with polyangiitis (EGPA))
    - cholesterol emboli
    - hematologic malignancy (myeloid and lymphoid variants), see *Chronic Myeloid Leukemia, H42* and *Hodgkin Lymphoma, H47*
    - adrenocortical insufficiency, see Endocrinology, E39
    - medications (penicillins)
    - atopic dermatitis

Basophilia and/or Eosinophilia
Can be an indicator of CML or other MPNs, associated with pruritus due to excessive histamine production

Investigations
- CBC and differential, peripheral smear assessing eosinophil morphology
- end organ involvement: electrolytes, renal function tests, LFTs, creatine kinase (CK), troponin, ECG, ECHO, pulmonary function tests (PFTs), CXR, chest and abdominal CT, consider BM biopsy

Treatment
- treat underlying cause
- before initiating steroids, ensure strongyloides serology is collected to rule out infection for patients at risk

Agranulocytosis

Definition
- ANC is <100/μL

Etiology
- associated with medications in 70% of cases: e.g. chemotherapy, clozapine, thionamides (antithyroid drugs), sulfasalazine, and ticlopidine
  - immune-mediated destruction of circulating granulocytes by drug-induced Abs or direct toxic effects upon marrow granulocytic precursors

Clinical Features
- abrupt onset of fever, chills, weakness, and oropharyngeal ulcers

Prognosis
- high fatality without vigorous treatment

Investigations/Treatment
- discontinue offending drug
- if patient is febrile, pan-culture and screen for infection (blood cultures x2, urine culture, and chest x-ray as minimum, initiate broad-spectrum antibiotics)
- consider BM aspirate and biopsy if cause unclear
- consider G-CSF

Leukemoid Reaction

Definition
- leukocytosis >50 x 10^9/L

Etiology
- infection
- drugs
- asplenia
- intoxication
- malignancy
- hemorrhage
- acute hemolysis

Investigations/Treatment
- marked left shift (myelocytes, metamyelocytes, and bands in peripheral blood smear)
- rule out CML and chronic neutrophilic leukemia
- detect and treat underlying cause

Approach to Lymphadenopathy

History
- constitutional/B-symptoms (seen in TB, lymphoma, other malignancies)
- growth pattern: acute vs. chronic
- exposures: cats (cat scratch – *Bartonella henselae*), ticks (Lyme disease – *Borrelia burgdorferi*), and high-risk behaviours (HIV)
- joint pain/swelling, rashes (connective tissue disorder)
- pruritus (seen in Hodgkin lymphoma)
- medications (can cause serum sickness → lymphadenopathy)

Constitutional/B-Symptoms

Unexplained temperature >38°C

Unexplained weight loss (>10% of body weight in 6 mo)

Night sweats

Clinical Features
- determine if lymphadenopathy is localized or generalized
- generalized: typically features of systemic diseases (HIV, TB, EBV, SLE, medications, sarcoidosis, lymphoma)
- localized: typically reactive or neoplastic
  - cervical (bacterial/mycobacterial infections, ENT malignancies, and metastatic cancer)
  - supraclavicular (highest malignancy risk)
    - right (mediastinal, bronchogenic, esophageal cancer)
    - left (gastric, gallbladder, pancreas, renal, and testicular/ovarian cancer)
  - axillary (cat scratch fever, breast cancer, and metastatic cancer)
  - epitrochlear (infections, sarcoidosis, and lymphoma)
- check for splenomegaly, constitutional symptoms

Lymphadenopathy-Causing Drugs
- Allopurinol
- Atenolol
- Captopril
- Carbamazepine
- Cephalosporins
- Gold
- Hydralazine
- Penicillin
- Phenytoin
- Primidone
- Pyrimethamine
- Quinidine
- Sulfonamides
- Sulindac

Investigations
- CBC and differential, blood film
- if generalized, consider tuberculin test, HIV RNA, VDRL, Monospot*/EBV serology, antinuclear antibodies (ANA), and imaging
- if localized and no symptoms suggestive of malignancy, can observe 3-4 wk (if no resolution → excisional biopsy to preserve lymph node architecture)
- in areas difficult to access (retroperitoneal, mediastinal/hilar), multiple core biopsies may be more practical/feasible
- FNA should NOT be used for diagnostic purposes in lymphoproliferative disease (excisional biopsy is the gold standard)
  - FNA is helpful for recurrence of solid tumour malignancy

Table 7. Inflammatory vs. Neoplastic Lymph Nodes

Feature	Inflammatory	Neoplastic
Consistency	Fluctuant/soft	Firm/hard
Mobility	Mobile	Matted/immobile
Tenderness	Tender	Non-tender
Size	<1 cm*	>1 cm*

Note: these classifications are not absolute; lymphoma and CLL nodes can feel rubbery and are frequently mobile, non-tender
*Note: inguinal lymph nodes can be up to 2 cm in size and non-pathologic

Table 8. Differential Diagnosis of Generalized Lymphadenopathy

Reactive	Inflammatory	Neoplastic
Bacterial (TB, Lyme, brucellosis, cat scratch disease, and syphilis)	Collagen disease (RA, dermatomyositis, SLE, vasculitis, and Sjögren's)	Lymphoproliferative disorder
Viral (EBV, CMV, HIV)	Drug hypersensitivity	Metastatic cancer
Parasitic (toxoplasmosis)	Sarcoidosis, amyloidosis	Histiocytosis X
Fungal (histoplasmosis)	Serum sickness	

Approach to Splenomegaly

Table 9. Differential Diagnosis of Splenomegaly

Increased Demand for Splenic Function			Congestive	Infiltrative
Hematological	**Infectious**	**Inflammatory**	**Cirrhosis**	**Non-Malignant**
Nutritional anemias	Viral e.g. EBV, HIV/ AIDS, CMV	SLE	Portal HTN	Benign metaplasia
Hemoglobinopathies	Bacterial e.g. bacterial endocarditis, TB	Sarcoidosis	Portal vein obstruction (including right heart failure)	Cysts
Hemolysis	Parasitic e.g. malaria, histoplasmosis, leishmaniasis	Felty syndrome	Splenic vein thrombosis	Amyloidosis
Spherocytosis	Fungal	Still's disease		Sarcoidosis
Sequestration crisis				Hamartomas
Elliptocytosis				Vascular abnormalities
				Lysosomal storage diseases (Gaucher's, Niemann-Pick)
				Glycogen storage diseases
				Malignant
				Leukemia (CML, CLL)
				Lymphoproliferative disease (CLL, NHL/HL)
				MPNs (CML, MF)
				Metastatic tumour

The underlined conditions cause massive splenomegaly (spleen crosses midline or reaches pelvis)

Causes of Splenomegaly

CHINA
Cirrhosis/Congestion (portal HTN)
Hematological
Infectious
Neoplasm
Autoimmune

History
- constitutional/B symptoms, feeling of fullness in LUQ, and early satiety
- signs or symptoms of infection (e.g. mononucleosis) or malignancy
- history of liver disease, hemolytic anemia, or high-risk exposures

Clinical Features
- jaundice, petechiae
- signs of chronic liver disease
- percussion (Castell's sign, Traube's space, and Nixon's method) and palpation
- associated LAD or hepatomegaly
- signs of CHF

Investigations
- CBC and differential, blood film
- as indicated: liver enzymes (AST, ALT, ALP, and GGT) and/or LFTs (platelet, INR, albumin, and bilirubin), reticulocyte count, Monospot*/EBV, haptoglobin, LDH, infectious and autoimmune workup, and BM biopsy/aspirate when malignancy suspected
- imaging
  - ultrasound of abdomen/liver to assess for cirrhosis and portal vein thrombosis (if positive, refer to hepatology)
  - echo for cardiac function
  - CT to rule out lymphoma and assess splenic lesions

Microcytic Anemia

- MCV <80 fL
- see *Figure 2, H6*

Table 10. Iron Indices and Blood Film in Microcytic Anemia

	Lab Tests					Blood Film
	Ferritin	Serum Iron	TIBC	% saturation	RDW	
Iron Deficiency Anemia	↓↓	↓	↑	↓	↑ (>15)	Hypochromic, microcytic
Anemia of Chronic Disease	N/↑	↓	↓	N	N	Normocytic/microcytic
Sideroblastic Anemia	N/↑	↑	N	N/↑	↑	Dual population Basophilic stippling
Thalassemia	N/↑	N/↑	N	N/↑	N/↑	Hypochromic, microcytic Basophilic stippling Poikilocytosis

Causes of Microcytic Anemia

TAILS
Thalassemia
Anemia of chronic disease/ inflammation
Iron deficiency
Lead poisoning
Sideroblastic anemia

Iron Metabolism

Iron Intake (Dietary)
- average North American adult diet = 10-20 mg iron daily
- steady state absorption is 5-10% (0.5-2 mg/d); enhanced by citric acid and ascorbic acid (vitamin C); reduced by polyphenols (e.g. in tea), phytate (e.g. in bran), dietary calcium, and soy protein
- males more likely to have positive iron balance; up to 20% of menstruating females have negative iron balance

Iron Absorption and Transport
- dietary iron is absorbed in the duodenum (absorption impaired in IBD and celiac disease)
- in circulation, the majority of non-heme iron is bound to transferrin which transfers iron from enterocytes and storage pool sites (macrophages of the reticuloendothelial system and hepatocytes) to RBC precursors in the BM

Iron Levels
- hepcidin is a hormone produced by hepatocytes that regulates systemic iron levels
  - binds to iron exporter ferroportin (on duodenal enterocytes and reticuloendothelial cells) and induces its degradation, thereby inhibiting iron export into circulation (iron trapping in reticuloendothelial system cells and diminished absorption of iron)
  - hepcidin production is
    - increased in states of iron overload (inhibiting additional iron absorption) and inflammation (mediating anemia of chronic disease through iron trapping)
    - decreased in states where erythropoiesis is increased (e.g. hemolysis) or oxygen tension is low

Iron Storage
- ferritin
  - ferric iron (Fe^{3+}) complexed to a protein called apoferritin (liver, spleen, and BM are main ferritin storage sites)
  - small quantities are present in plasma in equilibrium with intracellular ferritin
  - also an acute phase reactant – can be spuriously elevated to some extent despite low iron stores in response to a stressor
- hemosiderin
  - aggregates or crystals of ferritin with the apoferritin partially removed
  - macrophage-monocyte system is the main source of hemosiderin storage

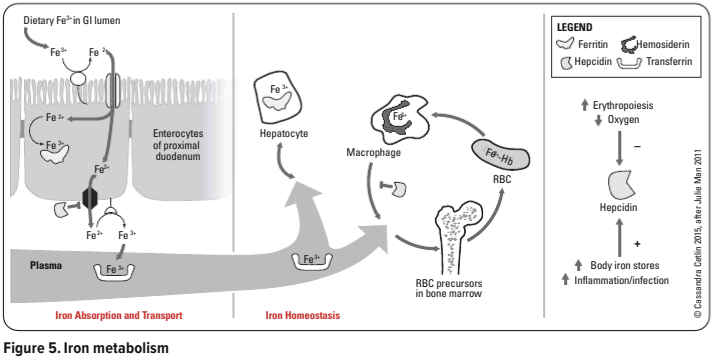

Figure 5. Iron metabolism

Iron Indices

- BM aspirate: gold standard test for assessment of iron stores (rarely done for this indication)
- serum ferritin: most important blood test for measuring iron stores
  - decreased in iron deficiency anemia
  - elevated in infection, inflammation, malignancy, liver disease, hyperthyroidism, and iron overload
- serum iron: measure of all non-heme iron present in blood
  - varies significantly daily
- TIBC: indirect measure of total amount of transferrin present in blood
  - normally, one third of TIBC is saturated with iron
  - increased TIBC has high specificity for decreased iron, low sensitivity
- transferrin saturation
  - serum iron divided by TIBC, expressed as a proportion or a percentage
- sTfR
  - reflects functional availability of iron at the tissue level
  - transferrin receptor is expressed on the surface of erythroblasts and is responsible for iron uptake – some are cleaved off and are present in circulation as sTfR
  - in iron deficient states, more transferrin receptors are expressed on erythroblasts leading to an

increase in sTfR
- sTfR also increased during extramedullary hematopoiesis (i.e. thalassemia syndromes)
- low in reduced erythropoiesis and iron overload
- useful in identifying iron deficiency in the setting of chronic inflammatory disorders (where ferritin levels can be elevated though iron stores are low; see *Iron Deficiency Anemia, H15*)

Iron Deficiency Anemia

- see Pediatrics, P51
- most common cause of anemia in North America

Etiology
- increased demand
  - increased physiological need for iron in the body (e.g. pregnancy)
- decreased supply: dietary deficiencies (rarely the only etiology in the developed world)
  - cow's milk (infant diet), "tea and toast" diet (elderly), absorption imbalances, post-gastrectomy, malabsorption (IBD of duodenum, celiac disease, autoimmune atrophic gastritis, and *H. pylori* infection)
- increased losses
  - hemorrhage
    - obvious causes: abnormal uterine bleeding, GI bleed
    - occult: peptic ulcer disease, GI cancer
  - hemolysis
    - chronic intravascular hemolysis (e.g. PNH, cardiac valve RBC fragmentation)

Plummer-Vinson Syndrome
- Dysphagia (esophageal)
- Glossitis
- Iron deficiency anemia
- Stomatitis

Iron deficiency anemia is a common presentation of chronic lower GI bleeds (right-sided colorectal cancer, angiodysplasia, etc.)
In males and in post-menopausal women, a GI workup is always warranted (gastroscopy, colonoscopy)

Clinical Features
- iron deficiency may cause fatigue before clinical anemia develops
- signs/symptoms of anemia: see *Anemia, H6*
- brittle hair, nail changes (brittle, koilonychia)
- pica (appetite for non-food substances, e.g. ice, paint, and dirt)
- restless leg syndrome

Investigations
- CBC, reticulocyte count, blood film, ferritin
  - low ferritin (<30 µg/L) is diagnostic of iron deficiency
  - ferritin is an acute phase reactant and is elevated in the setting of inflammatory conditions and liver disease; serum ferritin <100 µg/L in these settings is suggestive of iron deficiency, necessitating further workup - complete iron indices, consider sTfR (if available)
- peripheral blood film
  - hypochromic microcytosis: RBCs have low Hb levels due to lack of iron
  - pencil forms (oval-shaped RBCs)
  - anisocytosis (RBCs with irregular sharp projections)
  - target cells (RBCs with thicker cell membranes)
- BM aspirate (gold standard, but rarely done)
  - iron stain (Prussian blue) shows decreased iron in macrophages and in erythroid precursors (sideroblasts)
  - intermediate and late erythroblasts show micronormoblastic maturation

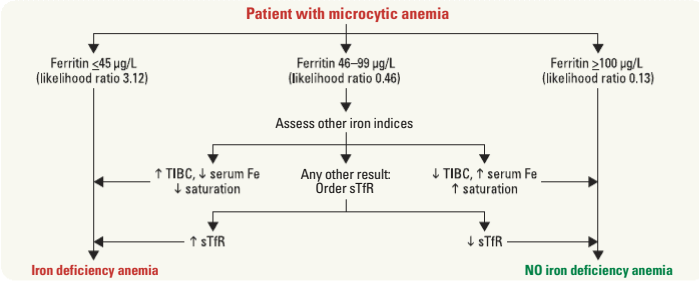

Figure 6. Approach to interpreting iron indices
Adapted from: Am Fam Physician 2007;75:671-678

Treatment
- treat underlying cause
- iron supplementation
  - oral (capsules, syrup)
    - ferrous sulphate 325 mg once daily (65 mg elemental iron), ferrous gluconate 300 mg once daily (35 mg elemental iron), or ferrous fumarate 300 mg once daily (100 mg elemental iron), polysaccharide iron complex (150 mg elemental iron), heme iron polypeptide (11 mg elemental iron)
    - supplement until anemia corrects, then continue for 3+ mo until serum ferritin returns to normal
    - recent studies demonstrate alternate day dosing may be non-inferior to daily or more frequent dosing, due to improved absorption, though this is still an area of investigation
    - there is no role for dosing oral iron more than once-daily; this results in hepcidin up-regulation and decreased absorption (and more side effects without clinical benefit)
  - IV iron can be considered if patient cannot tolerate or absorb oral iron, and/or if there is a need for quick recovery (e.g. chronic bleeding not manageable with oral iron)
- monitoring response
  - reticulocyte count will begin to increase after one wk
  - Hb increases by 10 g/L per wk (if no blood loss)

Anemia of Chronic Disease

(Also known as anemia of inflammation)

Etiology
- infection, malignancy, inflammatory, and rheumatologic disease
- chronic renal and liver disease
- endocrine disorders (e.g. diabetes mellitus, hypothyroidism, hypogonadism, and hypopituitarism)

Pathophysiology
- an anemia of underproduction due to impaired iron utilization (hepcidin is a key regulatory peptide)
  - hepatic hepcidin production is increased in inflammatory processes, trapping iron in enterocytes and macrophages (via ferroportin inhibition), see *Figure 5, H14*
  - reduced plasma iron levels make iron relatively unavailable for new Hb synthesis
  - marrow unresponsive to normal or slightly elevated EPO
- mild hemolytic component is often present i.e. RBC survival is modestly decreased

Investigations
- diagnosis of exclusion
- associated with elevation in acute phase reactants (ESR, CRP, fibrinogen, and platelets)
- peripheral blood
  - mild: usually normocytic and normochromic
  - moderate: may be microcytic and normochromic
  - severe: may be microcytic and hypochromic
  - absolute reticulocyte count is frequently low, reflecting overall decrease in RBC production
- "classic" serum iron indices: see *Table 10, H14*
- BM
  - normal or increased iron stores
  - decreased or absent staining for iron in erythroid precursors

Treatment
- treat underlying disease; only treat in patients who would benefit from a higher Hb
- IV iron if no benefit from PO iron (overcomes sequestration in enterocytes) or with use of ESAs in CKD
- EPO indicated in chronic renal failure; ensure Hb target <110 g/L (increased risk of vascular events/ischemic stroke with higher Hb targets)

Sideroblastic Anemia

- uncommon compared to iron deficiency anemia or anemia of chronic disease

Sideroblasts
- erythrocytes with small coarse or fine blue iron-containing (basophilic) granules in the cytoplasm
- "normal": granules are small and randomly spread in the cytoplasm
- "ring": iron deposits in mitochondria, forming large, abnormal granules that surround the nucleus
  - hallmark of sideroblastic anemia

Etiology
- due to defects in heme biosynthesis in erythroid precursors
- hereditary (rare): X-linked; median survival 10 yr
- idiopathic (acquired)
  - refractory anemia with ringed sideroblasts: a subtype of MDS (see *Myelodysplastic Syndromes, H41*)
  - may be a preleukemic phenomenon (1-2% transform to AML)
- reversible
  - drugs (isoniazid, chloramphenicol), alcohol, lead, copper deficiency, zinc toxicity, and hypothyroidism

Clinical Features
- anemia symptoms (see *Anemia, H6*)
- hepatosplenomegaly

Investigations
- serum iron indices: see *Table 10, H14*
- CBC and blood film
  - ring sideroblasts (diagnostic hallmark)
  - RBCs are hypochromic; can be micro-, normo-, or macrocytic
  - anisocytosis, poikilocytosis (abnormally shaped RBCs), basophilic stippling
- BM biopsy

Treatment
- depends on etiology
  - X-linked: high dose pyridoxine (vitamin B_6) in some cases
  - acquired: EPO and G-CSF
  - reversible: remove precipitating cause
- supportive transfusions for severe anemia
- monitor for iron overload driven by ineffective erythropoiesis and/or transfusion

Lead Poisoning

Definition/Etiology
- blood lead levels >80 µg/dL, may be symptomatic at 50 µg/dL
- identify source: consider occupational history, exposures history, and utensil history

Clinical Features
- pallor, abdominal pain, constipation, irritability, and difficulty concentrating

Treatment
- chelation therapy: dimercaprol and EDTA are first line agents

Consider lead poisoning in any child with microcytic anemia who lives in a house built before 1977

Features of Lead Poisoning

LEAD
Lead lines on gingivae and epiphyses of long bones on x-ray
Encephalopathy and Erythrocyte basophilic stippling
Abdominal colic and microcytic Anemia (sideroblastic)
Drops (wrist and foot drop)

Normocytic Anemia

- MCV 80-100 fL
- see *Figure 2, H6*

Aplastic Anemia

Definition
- destruction of hematopoietic cells of the BM leading to pancytopenia and hypocellular BM

Causes of Normocytic Anemia

ABCD
Acute blood loss
BM failure
Chronic disease
Destruction (hemolysis)

Etiology

Table 11. Etiology of Aplastic Anemia

Congenital	Acquired	
Fanconi syndrome Shwachman-Diamond syndrome Telomeropathies (dyskeratosis congenita)	**Idiopathic** Often T-cell mediated **Drugs** Dose-related (i.e. chemotherapeutics) Idiosyncratic (chloramphenicol, antimalarials, and phenylbutazone) **Toxins** Benzene/organic solvents, DDT, insecticides	**Ionizing Radiation** **Post-Viral Infection** Parvovirus B19, EBV, HDV, HEV, HBV, HHV6, HIV **Autoimmune (rare)** SLE, Graft-versus-host disease Others PNH, pregnancy, anorexia nervosa, and thymoma

Clinical Features
- can present acutely or insidiously
- symptoms of anemia (see *Anemia, H6*), thrombocytopenia (see *Thrombocytopenia, H7*), and/or infection
- ± splenomegaly and lymphadenopathy (depending on the cause)

Investigations
- exclude other causes of pancytopenia (see *Figure 4, H9*), including PNH (50% of aplastic anemia patients have PNH+ stem cell clones)
- CBC
  - anemia, neutropenia, or thrombocytopenia (any combination including pancytopenia)
  - decreased reticulocytes (<1% of the total RBC count)
- blood film
  - decreased number of normal RBCs
- BM aspirate and biopsy
  - aplasia or hypoplasia of cells with adipose tissue replacement
  - no evidence of infiltration with malignant cells or fibrosis

Treatment
- remove offending agents
- supportive care (RBC and platelet transfusions, antibiotics)
  - judicious use of blood products to decrease the risk of immune sensitization
  - iron chelation therapy for iron overload (accumulation of iron after multiple >20-unit RBC transfusions)
- immunosuppressive therapy (for idiopathic aplastic anemia)
  - horse or rabbit anti-thymocyte globulin: 40-50% of patients respond
  - cyclosporine (for improved response and survival)
- allogeneic BM transplant
- eltrombopag (TPO receptor agonist) shown to be effective; G-CSF and EPO not effective

Hemolytic Anemia

Definition
- anemia due to destruction and consequently shortened survival of circulating RBCs, usually defined as <100 d
- uncommon cause for anemia (<5% of cases) with many etiologies (>200)

Classification
- hereditary
  - abnormal membrane (spherocytosis, elliptocytosis)
  - abnormal enzymes (pyruvate kinase deficiency, G6PD deficiency)
  - abnormal Hb synthesis (hemoglobinopathies)
- acquired
  - immune
    - autoimmune: warm vs. cold AIHA, see *Table 14, Classification of AIHA, H23*
    - alloimmune: hemolytic disease of the fetus/newborn and post-transfusion
  - non-immune
    - TMA (includes MAHA): thrombus in blood vessel causes RBCs to be sheared – associated with DIC, HUS, aHUS, TTP, preeclampsia/HELLP, vasculitis, and malignant hypertension
    - other causes: PNH, hypersplenism, march hemoglobinuria (exertional hemolysis), infection (e.g. malaria), snake venoms, and mechanical heart valves
- also classified as intravascular or extravascular
  - intravascular: TMA and PNH (complement mediated)
  - extravascular: RBCs are coated with Abs (AIHA) or have an abnormal membrane structure/shape or inclusions
  - infections can cause intravascular (*Clostridium*), extravascular, or both (malaria)

On blood film, schistocytes reflect an intravascular hemolysis while spherocytes usually reflect an extravascular hemolysis

Disruption of the heme biosynthetic pathway causes **porphyria**

Porphyria
Inherited or acquired disorders of defective heme synthesis leading to accumulation of porphyrin precursors. Typically presents with non-specific clinical findings (abdominal pain, peripheral neuropathy, neuropsychiatric changes, and/or cutaneous photosensitivity)

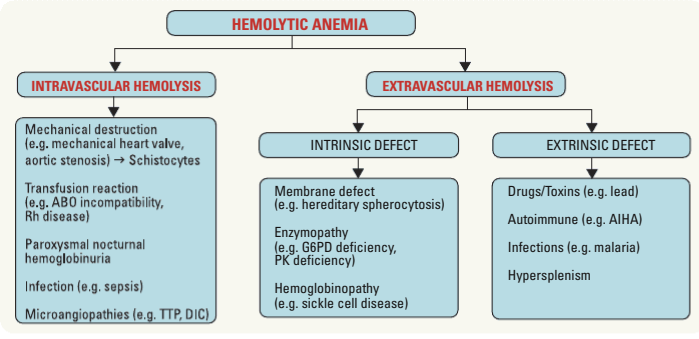

Figure 7. Hemolytic anemia

Heme Breakdown

Heme
↓ Heme oxygenase
Biliverdin
↓ Biliverdin reductase
Bilirubin

Haptoglobin is a circulating protein that mops up free Hb, allowing its clearance in the spleen; when free Hb is abundant, haptoglobin levels decrease

Clinical Features

- jaundice
- dark urine (hemoglobinuria, bilirubinuria)
- cholelithiasis (pigment stones)
- potential for an aplastic crisis (i.e. BM suppression in overwhelming infection)
- iron overload with extravascular hemolysis
- iron deficiency with intravascular hemolysis

Investigations

Table 12. Investigations for Hemolytic Anemia

Screening Tests	Tests Specific For Intravascular Hemolysis
Increased LDH	Schistocytes on blood film (MAHA)
Decreased haptoglobin	Free Hb in serum
Increased unconjugated bilirubin	Methaemalbuminaemia (heme + albumin)
Increased urobilinogen	Hemoglobinuria (immediate)
Reticulocytosis	Hemosiderinuria (delayed) – most sensitive
Tests Specific for Extravascular Hemolysis	
Direct Antiglobulin Test (direct Coombs) Detects IgG or complement on the surface of RBC Add anti-IgG or anti-complement Ab to patient's RBCs; positive if agglutination Indications: hemolytic disease of newborn, AIHA, hemolytic transfusion reaction	
Indirect Antiglobulin Test (indirect Coombs) Detects Abs in serum that can recognize antigens on RBCs Mix patient's serum + donor RBCs + Coombs serum (anti-human Ig Ab); positive if agglutination Indications: cross-matching donor RBCs, atypical blood group, blood group Ab in pregnant women, AIHA	

Thalassemia

Definition

- defects in production of the α or β chains of Hb
  - resulting imbalance in globin chains leads to ineffective erythropoiesis and hemolysis in the spleen or BM
- clinical manifestations and treatment depend on specific gene and number of alleles affected
- common features
  - increasing severity with increasing number of alleles involved
  - hypochromic microcytic anemia
  - basophilic stippling, abnormally shaped RBCs on blood film
  - CBC: low MCV, low Hb, high RBC count, ± high reticulocyte count

Thalas"SEA"mia

β-thalassemia → more prevalent in Mediterranean
α-thalassemia → more prevalent in South East Asia (SEA) and Africa
(α = Asia, Africa)

Pathophysiology

- defect may be in any of the Hb genes
  - normally 4 α genes in total; 2 on each copy of chromosome 16
  - normally 2 β genes in total; 1 on each copy of chromosome 11
  - fetal Hb, HbF ($\alpha_2\gamma_2$), switches to adult forms HbA ($\alpha_2\beta_2$) and HbA2 ($\alpha_2\delta_2$) at age 3-6 mo
  - HbA constitutes 97% of adult Hb
  - HbA2 constitutes 3% of adult Hb

β-Thalassemia Minor (Thalassemia Trait)

Definition
- defect in single allele of β gene (heterozygous for one normal β globin allele and one β globin thalassemia allele)
- common in people of Mediterranean and South Asian descent

Clinical Features
- usually asymptomatic; a palpable spleen is very rare

Investigations
- Hb (100-140 g/L), MCV (<70 fL), Fe (normal), RBC count (normal/high)
- peripheral blood film – microcytosis, basophilic stippling
- Hb electrophoresis
  - specific: HbA2 increased to 3.5-5% (normal 1.5-3.5%)
  - non-specific: 50% have slight increase in HbF

Treatment
- no treatment required
- genetic counselling for patient and family

Microcytosis in β-Thalassemia Minor
Microcytosis is more profound and the anemia is much milder than that of iron deficiency

β-Thalassemia Major

Definition
- defect in both alleles of β gene (homozygous, autosomal recessive)

Pathophysiology
- ineffective chain synthesis leading to decreased erythropoiesis, hemolysis of RBCs, and increase in HbF

Clinical Features
- initial presentation at age 6-12 mo when HbA (α_2/β_2) normally replaces HbF (α_2/γ_2)
  - severe anemia, jaundice
- iron overload due to compensatory gastrointestinal iron uptake progressing to hemochromatosis
  - secondary to repeated transfusions and ineffective erythropoiesis (through an erythroferrone-mediated mechanism)
  - results in iron-induced organ damage
- stunted growth and development (due to hypogonadism)
- gross hepatosplenomegaly (due to extramedullary hematopoiesis)
- radiologic changes (due to expanded marrow cavity) and extramedullary hematopoietic masses (erythroid tissue tumours)
  - skull x-ray has "hair-on-end" appearance
  - pathologic fractures common
- evidence of increased Hb catabolism (e.g. pigmented gallstones)
- death can result from:
  - untreated anemia (should transfuse)
  - infection (should identify and treat early)
  - iron overload (common, late complication)

Hemochromatosis Clinical Features

ABCDH
Arthralgia
Bronze skin
Cardiomyopathy, Cirrhosis of liver
Diabetes (pancreatic damage)
Hypogonadism (anterior pituitary damage)

Investigations
- CBC and iron studies
- severe microcytic anemia (Hb <60 g/L)
- peripheral blood film: teardrop, target, hypochromic, microcytic
- Hb electrophoresis
  - HbA: 0-10% (normal >95%)
  - HbA2 >2.5%
  - HbF: 90-100%

Treatment
- life-long regular RBC transfusions to suppress endogenous erythropoiesis
- iron chelation (e.g. deferoxamine, deferasirox, and deferiprone) to prevent iron overload in organs and the formation of free radicals (which promote tissue damage and fibrosis)
- folic acid supplementation if not transfused
- allogeneic BM transplantation (potentially curative) or cord blood transplant
- gene therapy (to encode adult Hb A) or CRISPR-Cas 9 gene editing (to allow for increased HbF production) under study
- splenectomy (now performed less frequently)

β-Thalassemia Intermedia

Definition
- clinical diagnosis in patients whose clinical manifestations are too mild to be classified as β-thalassemia major, but too severe to be classified as β-thalassemia minor

Clinical Features
- wide variety of clinical phenotypes
- in most cases of β-thalassemia intermedia, both β-globin genes are affected
- three main mechanisms account for the milder phenotype compared to β-thalassemia major: (1) subnormal (vs. absent) β-chain synthesis, (2) increased number of γ chains, and (3) coinheritance of α-thalassemia (in some cases)
- complications more commonly seen in β-thalassemia intermedia than β-thalassemia major include extramedullary hematopoiesis, leg ulcers, gallstones, thrombosis, pulmonary hypertension, and growth retardation

Treatment
- most patients only require periodic transfusions, although regular transfusions may eventually be necessary in adulthood (third to fourth decade of life)
- folic acid supplementation if not transfused
- iron chelation therapy may be needed to mitigate iron overload from ineffective erythropoiesis and subsequent hepcidin downregulation via erythroferrone; can assess liver iron concentration (LIC) with an MRI, chelation should be considered if LIC >5 mg/g

α-Thalassemia

Definition
- defect(s) in α genes
- similar geographic distribution as β-thalassemia, but higher frequency among Southeast Asians and Africans

Clinical Features
- 1 defective α gene (aa/a-): clinically silent; normal Hb, normal MCV
- 2 defective α genes (cis: aa/-- or trans: a-/a-): normal Hb, decreased MCV
  - N.B. cis 2-gene deletion more common in Asia vs. trans 2-gene deletion more common in Africa – this leads to increased risk of fetal hydrops in offspring of patients from Southeast Asia vs. Africa
- 3 defective α genes (a-/--): HbH (β4) disease; presents in adults, decreased Hb, decreased MCV, and splenomegaly
- 4 defective α genes (--/--): Hb Barts (γ4) disease (hydrops fetalis); usually incompatible with life

Investigations
- CBC and iron studies (for iron overload)
- peripheral blood film – screen for HbH inclusion bodies with supravital stain
- Hb electrophoresis can be used to identify HbH disease, but may miss 1- or 2-gene deletions; definitive diagnosis with DNA genotyping

Treatment
- referral for genetic/prenatal counselling
- depends on degree of anemia
  - 1 or 2 defective α genes: no treatment required
  - HbH disease: similar to β-thalassemia intermedia
  - Hb Barts: no definitive treatment
    - majority of pregnancies terminated (fetal/maternal mortality risk)
    - intrauterine transfusion, stem cell transplants

Sickle Cell Disease

Definition
- autosomal recessive sickling disorders are most commonly caused by a Glu → Val substitution at position 6 of the β-globin chain (chromosome 11) resulting in HbS variant, rather than HbA (normal adult Hb)
  - increased incidence of HbS allele in patients with Sub-Saharan African, Indian, Middle Eastern, or Mediterranean heritage (thought to be protective against malaria)
- SCD occurs when an individual has two HbS genes (homozygous, HbSS) or one HbS gene + another mutant β-globin gene (compound heterozygote) – most commonly HbS-β-thal and HbSC disease

Pathophysiology
- at low pO_2, deoxyHbS polymerizes leading to rigid crystal-like rods that distort membranes → 'sickles'
- the pO_2 level at which sickling occurs is related to the percentage of HbS present
- sickling is aggravated by acidemia, increased CO_2, increased 2,3-DPG, fever, and increased osmolality
- fragile sickle cells then cause injury in two main ways
  1. fragile sickle cells hemolyze (nitric oxide depletion)
  2. occlusion of small vessels (hypoxia, ischemia-reperfusion injury)

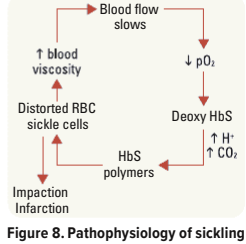

Figure 8. Pathophysiology of sickling

Functional Asplenism: increased susceptibility to infection by encapsulated organisms
- *S. pneumoniae*
- *N. meningitidis*
- *H. influenzae*
- *Salmonella (osteomyelitis)*

Clinical Features

- sickle cell trait (HbAS): asymptomatic except during extreme hypoxia or infection
  - increased risk of renal medullary carcinoma
- SCD-SS (HbSS)
  - chronic hemolytic anemia
  - jaundice in the first year of life
  - retarded growth and development ± skeletal changes
  - splenomegaly in childhood; splenic atrophy in adulthood
- SCD-SS often presents with acute pain episode
  1. aplastic crises
     - toxins and infections (especially parvovirus B19) transiently suppress BM
  2. splenic sequestration crises
     - usually in children; significant pooling of blood in spleen resulting in acute Hb drop and shock
     - uncommon in adults due to asplenia from repeated infarction
  3. vaso-occlusive crises (microcirculation infarction)
     - may affect various organs causing ischemia-reperfusion injury (especially in back, chest, abdomen, and extremities), fever, and leukocytosis
     - can cause a stroke or a silent MI
     - precipitated by infections, dehydration, rapid change in temperature, pregnancy, menses, and alcohol
  4. acute chest syndrome
     - acute illness characterized by fever and/or respiratory symptoms
     - new pulmonary infiltrate on chest x-ray
     - precipitated by pulmonary infection, fat emboli, and pulmonary infarction
- SCD-SC (HbSC): most common compound heterozygote
  - 1 in 833 live births in African-Americans, common in West Africa
  - milder anemia than HbSS
  - similar complications as HbSS but typically milder and less frequent (exception is proliferative sickle cell retinopathy, glomerulonephritis, and avascular necrosis)
  - spleen not always atrophic in adults

Organs Affected by Vaso-Occlusive Crisis

Organ	Problem
Brain	Ischemic or hemorrhagic stroke, vasculopathy
Eye	Hemorrhage, blindness
Liver	Infarcts, RUQ syndrome
Lung	Acute chest syndrome, long-term pulmonary hypertension
Gallbladder	Stones
Heart	Hyperdynamic flow murmurs
Spleen	Enlarged (child); atrophic (adult)
Kidney	Hematuria, loss of renal concentrating ability, proteinuria
Intestines	Acute abdomen
Placenta	Stillbirths
Penis	Priapism
Digits	Dactylitis
Bone	Infarction, infection, avascular necrosis (femoral and humeral head)
Skin	Leg ulcers (ankle)

Investigations

- sickle cell prep (detects sickling of RBCs under the microscope in response to O_2 lowering agent): determines the presence of a HbS allele, but does not distinguish HbAS from HbSS
- Hb electrophoresis distinguishes HbAS, HbSS, HbSC, and other variants
- all newborns in developed countries typically screened for SCD

Table 13. Investigations for Sickle Cell Disease

	HbAS	HbSS
CBC	Normal	Increased reticulocytes, decreased Hb, and decreased Hct
Peripheral Blood	Normal; possibly a few target cells	Sickled cells
Hb Electrophoresis	HbA fraction of 0.65 (65%) HbS fraction of 0.35 (35%)	No HbA, only HbS and HbF (proportions change with age); normal amount of HbA2

Treatment

- genetic counselling
- HbAS: no treatment required
- HbSC: treatment as per HbSS, but is dictated by symptom severity
  1. folic acid to prevent folate deficiency
  2. hydroxyurea (HU) to enhance production of HbF
     - mechanism of action = stops repression of fetal Hb-γ gene thereby increasing production of stem cells expressing HbF (HbF decreases polymerization and precipitation of HbS in sickle cell RBCs)
     - short-term harms (within 6 mo): dose-related leukopenia, thrombocytopenia, anemia, and decreased reticulocyte count; decreased sperm production, mucositis, skin ulcers
     - long-term harms: potentially birth defects in offspring of people receiving the drug, growth delays in children receiving the drug, and cancer in both children and adults who receive the drug
  3. treatment of vaso-occlusive crisis
     - supportive care: oxygen, hydration (reduces viscosity), correct acidosis, analgesics/opiates
     - indication for exchange transfusion: SCD complications (acute chest syndrome, aplastic crises, hepatic or splenic sequestration, and stroke), prevention of complications, preoperative
     - less routinely: antimicrobials for suspected infection
  4. prevention of crises
     - establish diagnosis
     - avoid conditions that promote sickling (hypoxia, acidosis, dehydration, and fever)
     - vaccination in childhood (*S. pneumoniae, N. meningitidis*, and *H. influenzae* type b)
     - prophylactic penicillin (age 3 mo-5 yr)
     - good hygiene, nutrition, and social support

Hydroxyurea (Hydroxycarbamide) for Sickle Cell Disease
Cochrane DB Syst Rev 2017;4:CD002202
Purpose: To assess the effects of hydroxyurea therapy in patients of any age and genotype with sickle cell disease (SCD).
Study Selection: Randomised and quasi-randomised controlled trials ≥1 month comparing hydroxyurea with placebo, standard therapy or other interventions.
Results: 8 RCTs were included, 899 total patients (both adults and children with SCD). When compared to placebo, hydroxyurea was associated with statistically significant improvements in pain alteration (pain crisis frequency, duration, intensity, hospital admissions and opioid use), measures of HbF and neutrophil counts, and fewer occurrences of acute chest syndrome and blood transfusions. Differences in quality of life and adverse events (including serious or life-threatening events) were not statistically significant.
Conclusion: Evidence suggests that hydroxyurea can effectively decrease the frequency of pain episodes and other acute complications in patients with SCD. However, data on the long-term benefits and risks of hydroxyurea is still insufficient.

5. screen for complications
   - regular blood work (CBC, reticulocytes, iron indices, BUN, LFTs, and creatinine)
   - urinalysis annually (proteinuria and glomerulopathy)
   - transcranial doppler annually until 16 yr (stroke prevention)
   - retinal examinations annually from 8 yr (screen for retinopathy)
   - echocardiography once in late childhood/early adulthood (screen for pulmonary hypertension)
6. newer therapies
   - gene therapy
   - voxelotor
   - crizanlizumab

Stroke With Transfusions Changing to Hydroxyurea (SWiTCH)
Blood 2012;119:3925-32
Purpose: To compare standard treatment (transfusions/chelation) to alternative treatment (hydroxyurea/phlebotomy) for children with sickle cell anemia (SCA), stroke, and iron overload.
Methods: 133 pediatric patients were randomized to (1) continuation of monthly erythrocyte transfusions with oral deferasirox (28.2 ± 6.0 mg/kg/d) or (2) initiation on hydroxyurea (20 mg/kg/d escalated to maximum tolerated dose (MTD)=26.2 ± 4.9 mg/kg/d) with discontinuation of transfusions at MTD, and monthly phlebotomy (5-10 mL/kg/mo) for iron overload.
Primary Outcome: Secondary stroke recurrence rate and quantitative liver iron content.
Results: Stroke recurrence rate was significantly lower in patients on transfusions/deferasirox as compared to those initiated on hydroxyurea/phlebotomy (0% vs. 10%, P<0.05). Differences in liver iron content between the two treatment arms were not statistically different (16.6 mg/g dry weight liver in transfusions/deferasirox vs. 15.7 mg/g in hydroxyurea/phlebotomy).
Conclusion: Transfusions and chelation remain the preferred management strategies for pediatric patients with SCA, stroke, and iron overload.

Autoimmune Hemolytic Anemia

Table 14. Classification of AIHA

	Warm (75-90% cases)	Cold
Ab Allotype	IgG	IgM
Agglutination Temperature	37°C	4-37°C
Direct Coombs Test (direct antiglobulin test)	Positive for IgG ± complement	Positive for complement
Etiology	Idiopathic Secondary to lymphoproliferative disorder (e.g. CLL, Hodgkin lymphoma) Secondary to autoimmune disease (e.g. SLE) Pregnancy Drug-induced (e.g. penicillin, quinine, methyldopa)	Idiopathic Secondary to infection (e.g. mycoplasma pneumonia, EBV, HCV, syphilis) Secondary to lymphoproliferative disorder (e.g. macroglobulinemia, CLL)
Blood Film	Spherocytes	Agglutination
Management	Treat underlying cause Folic acid Corticosteroids (1st-line) Folic acid Rituximab (2nd-line to steroids) Immunosuppression Splenectomy	Treat underlying cause Folic acid Warm patient/avoid cold Rituximab regimen (1st-line) Plasma exchange (2nd-line for high IgM levels) Low dose alkylating agents (chlorambucil, cyclophosphamide) or interferon may be useful but less effective

Microangiopathic Hemolytic Anemia (MAHA)/Thrombotic Microangiopathy (TMA)

Definition
- hemolytic anemia due to intravascular fragmentation of RBCs

Etiology
- see *Thrombotic Thrombocytopenic Purpura (TTP), H31*
- *see Hemolytic Uremic Syndrome, H31*
- see *Disseminated Intravascular Coagulation, H34*
- eclampsia, HELLP syndrome, AFLP
- malignant hypertension
- vasculitis
- malfunctioning heart valves
- metastatic carcinoma
- drugs (calcineurin inhibitors, quinine, simvastatin)
- infections (severe CMV or meningococcus)
- catastrophic APS

Investigations
- blood film: schistocytes
- hemolytic workup (CBC, reticulocyte count, LDH, haptoglobin, indirect bilirubin)
- Coombs test: negative
- urine: hemosiderinuria, hemoglobinuria

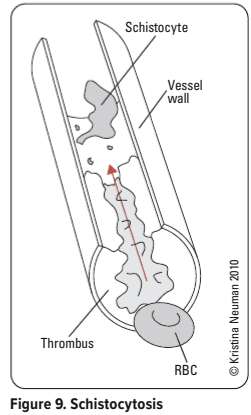

Figure 9. Schistocytosis

Hereditary Spherocytosis

Definition/Etiology
- most common type of hereditary hemolytic anemia
- abnormality in RBC membrane proteins (e.g. spectrin)
- autosomal dominant (variable penetrance), can also be autosomal recessive or de novo
- presents with hemolytic anemia, jaundice, splenomegaly

Investigations
- CBC and differential blood film (shows spherocytes)
- RBC dehydration and membrane loss result in elevated MCHC
- osmotic fragility (increased)
- molecular analysis for spectrin gene
- U/S (splenomegaly and gallstones (pigment))

Treatment
- genetic counselling
- in severe cases, splenectomy (avoid splenectomy in early childhood); vaccination against *S. pneumoniae*, *N. meningitidis*, and *H. influenzae* type b pre-splenectomy

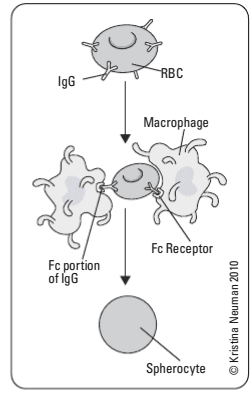

Figure 10. Spherocytosis secondary to AIHA

Hereditary Elliptocytosis

Definition/Etiology
- abnormal interactions between spectrin and other membrane proteins
- autosomal dominant
- 25-75% elliptocytes
- hemolysis is usually mild

Treatment
- genetic counselling
- if severe hemolysis: folate supplementation, immunization, splenectomy

Glucose-6-Phosphate Dehydrogenase Deficiency

Definition/Etiology
- deficiency in G6PD leading to a lack of reduced glutathione and increased RBC sensitivity to oxidative stress
- X-linked recessive, prevalent in individuals of African, Asian, and Mediterranean descent

Clinical Features
- frequently presents as episodic hemolysis precipitated by:
  - oxidative stress
  - drugs (e.g. sulfonamide, antimalarials, and nitrofurantoin)
  - infection
  - food (fava beans)
- in neonates: can present as prolonged, pathologic neonatal jaundice

Investigations
- neonatal screening
- G6PD assay (may not be useful if result is normal)
  - should not be done in acute crisis when reticulocyte count is high (reticulocytes have high G6PD levels)
- blood film
  - Heinz bodies (clumps of denatured Hb attached to RBC membrane)
  - bite cells (indicative of oxidative hemolysis; generated by passage through spleen)

Treatment
- genetic and prenatal counselling
- folic acid
- stop offending drugs and avoid triggers
- transfusion in severe cases

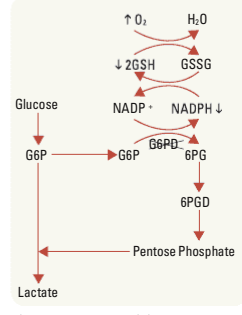

Figure 11. G6PD deficiency

Macrocytic Anemia

- MCV >100 fL
- see *Figure 2, H6*

Table 15. Comparison Between Megaloblastic and Non-Megaloblastic Macrocytic Anemia

	Megaloblastic	Non-Megaloblastic
Morphology	Large, oval, nucleated RBC precursor Hypersegmented neutrophils	Large round RBC Normal neutrophils
Pathophysiology	Failure of DNA synthesis resulting in asynchronous maturation of RBC nucleus and cytoplasm	Reflects membrane abnormality with abnormal cholesterol metabolism

Note: MDS is a non-megaloblastic macrocytic anemia that commonly presents with oval macrocytosis

Causes of Macrocytic Anemia

ABCDEF
Alcoholism (liver disease)
B$_{12}$ deficiency
Compensatory reticulocytosis
Drugs (cytotoxic, azidothymidine)/ Dysplasia
Endocrine (hypothyroidism)
Folate deficiency/Fetus (pregnancy)

Characteristics of Megaloblastic Macrocytic Anemia
Pancytopenia
Hypersegmented neutrophils
Megaloblastic BM

Vitamin B$_{12}$ Deficiency

- B$_{12}$ (cobalamin)
- binds to intrinsic factor (IF) secreted by gastric parietal cells
- absorbed in terminal ileum
- total body stores sufficient for 3-4 yr

Etiology

Table 16. Etiology of Vitamin B$_{12}$ Deficiency

Diet	Gastric	Intestinal Absorption	Genetic
Strict vegan More likely to present in pediatric population Vegetarian in pregnancy Malnutrition	**Mucosal atrophy** Gastritis, autoimmune **Pernicious anemia (see below)** **Post-gastrectomy**	**Malabsorption** Crohn's, celiac disease, pancreatic insufficiency, *H. pylori* **Stagnant bowel** Blind loop, stricture **Fish tapeworm** **Resection of ileum** **Drugs** Neomycin, biguanides, proton pump inhibitors, N_2O anesthesia, metformin	**Transcobalamin II deficiency** **IF receptor defect**

Pathophysiology of Pernicious Anemia

- auto-Abs produced against gastric parietal cells leading to achlorhydria and lack of IF secretion
- IF is required to stabilize B$_{12}$ as it passes through the bowel
- decreased IF leads to decreased ileal absorption of B$_{12}$
- may be associated with other autoimmune disorders (polyglandular endocrine insufficiency)
- most common in Northern European White populations, usually >30 yr (median age of 60 yr)

Clinical Features

- neurological (severity of anemia and neurological sequelae depends on deficiency)
  - peripheral neuropathy (variable reversibility)
    - usually symmetrical, affecting lower limbs more than upper limbs
  - spinal cord (irreversible damage)
    - subacute combined degeneration
    - posterior columns: decreased vibration sense, proprioception, 2-point discrimination, and paresthesia
    - pyramidal tracts: spastic weakness, ataxia
  - cerebral (common, reversible with B$_{12}$ therapy)
    - confusion, delirium, and dementia
  - cranial nerves (rare)
    - optic atrophy

Investigations

- CBC, reticulocyte count
  - anemia often severe ± neutropenia ± thrombocytopenia
  - MCV >110 fL
  - low reticulocyte count relative to the degree of anemia (<2%)
- serum B$_{12}$ and RBC folate
  - caution: lower serum B$_{12}$ leads to low RBC folate; absence of B$_{12}$ results in folate polyglutamate synthesis failure
  - alternatively, can measure elevated urine metabolites (methylmalonate, homocysteine)
- blood film
  - oval macrocytes, hypersegmented neutrophils

- BM
  - hypercellularity due to abnormal proliferation and maturation of multiple myeloid cell lines
  - nuclear-cytoplasmic asynchrony in RBC precursors (less mature nuclei than expected from the development of the cytoplasm)
- celiac disease testing
- bilirubin and LDH
  - elevated unconjugated bilirubin and LDH due to breakdown of cells in BM
- pernicious anemia investigations: anti-parietal cell Ab (more sensitive), anti-intrinsic factor Ab (more specific), gastrin level (elevated), upper endoscopy (for biopsy - atrophic gastritis, also to screen for gastric malignancy)

Treatment
- treatment dose = vitamin B12 1000-1200 µg PO once daily if intestinal absorption intact or 1000 µg IM weekly; route and duration depends on cause
- maintenance dose (once replete) = vitamin B_{12} 1000 µg PO once daily or 1000 µg IM monthly
- watch for hypokalemia and rebound thrombocytosis when treating severe megaloblastic anemia

Folate Deficiency

- uncommon in developed countries due to extensive dietary supplementation (enriched in flour)
- folate stores are depleted in 3-6 mo
- folate commonly found in green, leafy vegetables, and fortified cereals
- maternal folate deficiency is associated with fetal neural tube defects

Etiology

Table 17. Etiology of Folate Deficiency

Diet/Deficiency	Malabsorption	Drugs	Increased Demand
Alcohol use disorder	Celiac disease	Anti-folates (methotrexate)	Pregnancy
Substance misuse	IBD	Anticonvulsants (phenytoin)	Hemolysis
Elderly/infants	Short bowel syndrome	Alcohol	Prematurity
Poor intake		Oral contraceptive	Exfoliative dermatitis/psoriasis
			Hemodialysis

Clinical Features
- anemia, mild jaundice, glossitis, diarrhea, confusion, pallor
- consider social history, alcohol use disorder/substance misuse, very poor diet (e.g. elderly, depressed)

Investigations
- similar to B_{12} deficiency (CBC, reticulocytes, blood film, RBC folate, and serum B_{12})
- if decreased RBC folate, rule out B_{12} deficiency as cause

Management
- folic acid 1-5 mg PO once daily x 1-4 mo; then 1 mg PO once daily maintenance if cause is not reversible

Never give folate alone to an individual with megaloblastic anemia because it will mask B_2 deficiency and neurological degeneration will continue

Hemostasis

Stages of Hemostasis

1. Primary Hemostasis
- mediated by platelets and VWF
- goal is rapid cessation of bleeding; main effect is on mucocutaneous bleeding
- vessel injury results in collagen/subendothelial matrix exposure and release of vasoconstrictors
- blood flow is impeded and platelets come into contact with damaged vessel wall (*Figure 12a, H27*)
  - adhesion: platelets adhere to subendothelium via VWF
  - activation: platelets are activated resulting in morphology change, and granule release
  - aggregation: activated GPIIbIIIa on platelets binds soluble ligands, which results in aggregation and the formation of a localized platelet plug

2. Secondary Hemostasis
- platelet plug is reinforced by production of a fibrin clot (*Figure 12b, H27*)
- extrinsic (initiation) pathway: initiation of secondary hemostasis
- intrinsic (amplification) pathway: amplification once secondary hemostasis has started via positive feedback
- both the intrinsic and extrinsic pathways converge onto the common pathway, which results in thrombin generation and fibrin formation

3. Fibrin Stabilization
- conversion from a soluble to an insoluble, cross-linked clot

4. Fibrinolysis
- once healing is initiated, clot dissolution is mediated by the fibrinolytic system

Phases of Hemostasis
Primary Hemostasis
Vascular response and platelet plug formation via VWF
Secondary Hemostasis
Fibrin clot formation
Fibrin Stabilization
Fibrinolysis

Check out this educational module created by St. Michael's Hospital residents and hematology faculty: www.coagtesting.com

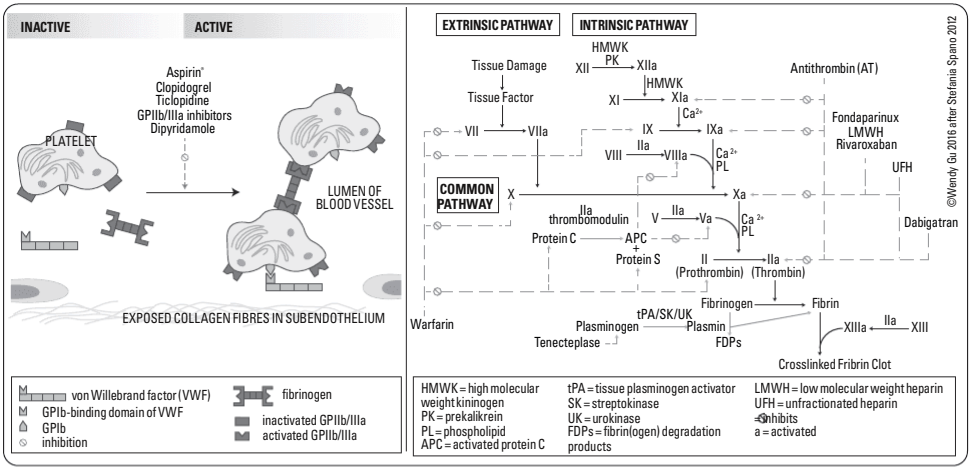

Figure 12a. Platelet activation

Figure 12b. Coagulation cascade

Table 18. Commonly Used Tests of Hemostasis

Type of Hemostasis	Test	Typical Reference Range (lab dependent)	Purpose	Examples of Associated Diagnoses
Primary	Platelet count	150-400 x 10^9/L	To quantitate platelet number	Low in ITP, HUS/TTP, DIC, HIT
Secondary	PTT	28-38 s	Measures intrinsic pathway (factors VIII, IX, XI, XII) and common pathway Used to monitor heparin and argatroban therapy	Prolonged in hemophilia A and B (if factor deficiency is below reagent threshold of detection) N.B. Prolonged if lupus anticoagulant present (inhibits pathway *in vitro*)
	PT	10-13 s	Measures extrinsic pathway (factor VII) and common pathway	Prolonged in vitamin K deficiency, vitamin K antagonist therapy (warfarin), factor VII deficiency
	INR	0.9-1.2	Used to monitor warfarin therapy and for assessment of hepatic function	
	Mixing studies		May differentiate inhibitors of coagulation factor(s) from a deficiency in coagulation factors Mix patient's plasma with normal plasma in 1:1 ratio and repeat abnormal test	Normalization of coagulation time if deficiency of single coagulation factor (normalization may not occur if multiple coagulation factors are deficient) Lack of normalization if inhibitor present
Fibrinolysis	Euglobulin lysis time	N >90 min	Looks for accelerated fibrinolysis	May be shortened (increased fibrinolysis) in DIC or factor XIII deficiency
Other	Fibrinogen D-dimer Specific factor assays (e.g. factor VIII) Lupus anticoagulant von Willebrand tests (VWF antigen, Ristocetin cofactor activity (VWF activity), factor VIII)			

Note: INR is mathematically derived from PT

Table 19. General Rules of Thumb: Signs and Symptoms of Disorders of Hemostasis

	Primary (Platelet, VWF)	Secondary (Coagulation)
Surface Cuts	Excessive, prolonged bleeding	Normal/slightly prolonged bleeding
Onset After Injury	Immediate	Delayed
Site of Bleeding	Superficial i.e. mucosal (nasal, gingival, GI tract, vaginal), skin	Deep i.e. joints, muscles (excessive, post-traumatic)
Lesions	Petechiae, ecchymoses	Hemarthroses, hematomas

Tests of Secondary Hemostasis

PT/INR: Tennis is played outside (Extrinsic pathway)
PTT: Table **T**ennis is played inside (Intrinsic pathway)

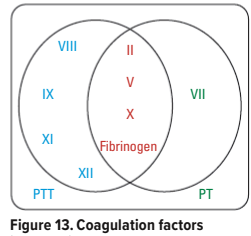

Figure 13. Coagulation factors involved in PT and PTT

Causes of a Prolonged PTT without Bleeding include:
1. Early contact factor (Factor XII, HMWK, PK) deficiency
2. Lupus anticoagulant
3. Inappropriate blood draw
4. Laboratory error

Consider PTT
IV heparin, argatroban monitoring
Factor VIII deficiency (Hemophilia A), Factor IX deficiency (Hemophilia B), factor XI deficiency, severe VWD

Table 20. Lab Values in Disorders of Hemostasis

	PT	PTT	Platelet Count	Hb
Hemophilia A/B	N	↑	N	N*
VWD	N	±	N/↓	N*
DIC	↑	↑	↓	N/↓
Liver Failure	↑	N/↑	N/↓	N
ITP	N	N	↓	N*
TTP	N	N	↓	↓

* = anemia may develop from progressive iron deficiency and/or active bleeding

Consider PT/INR
Warfarin
Liver disease
Risk factor for vitamin K deficiency (e.g. malabsorption, cholestasis, malnutrition)

Consider both PTT and PT/INR
Suspected DIC
Trauma patient, or requiring massive transfusion protocol
Bleeding patient
Patient receiving thrombolytic therapy

Disorders of Primary Hemostasis

Definition

- inability to form an adequate platelet plug due to:
  - disorders of blood vessels
  - disorders of platelets: abnormal function/numbers
  - disorders of VWF
- characterized as immediate bleeding, mucocutaneous bleeding, and manifesting as petechiae/ecchymosis/ epistaxis/ gum bleeding/ menorrhagia

Classification

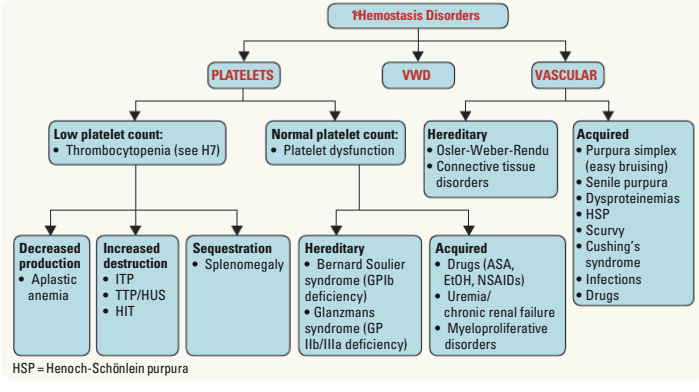

Figure 14. Approach to disorders of primary hemostasis

Drugs Commonly Associated with Thrombocytopenia

Trimethoprim/ sulfamethoxazole	Heparin	NSAIDs
Vancomycin	Digoxin	Acetaminophen
Rifampin	Amiodarone	Ethanol
Ethambutol	Quinidine	H2-antagonists
Amphotericin B	Quinine (common)	Chemotherapy

Immune Thrombocytopenia

Table 21. Features for Childhood vs. Adult Immune Thrombocytopenia

Features	Childhood ITP (see Pediatrics, P53)	Adult ITP
Peak Age	2-6 yr	20-40 yr
Gender	F=M	F>M
History of Recent Infection	Common	Rare
Duration	Usually wk	Mo to yr
Spontaneous Remissions	80% or more	Uncommon

Definition

- a disease of low platelet count (see *Thrombocytopenia, H7*) secondary to aberrant immune responses

Terminology of ITP

- primary: ITP (platelet count <100 x 10^9/L) with no other cause of thrombocytopenia
- secondary: ITP associated with another condition (e.g. HIV, HCV, SLE, or CLL)
- drug-induced: platelet destruction caused by anti-platelet Abs secondary to drug exposure

Classification of Primary ITP

- acute: 3 mo from diagnosis
- persistent: 3-12 mo from diagnosis

- chronic: >12 mo from diagnosis
- refractory: post-splenectomy

Pathophysiology
- primary or secondary ITP
- an acquired immune-mediated disorder
  - increased platelet destruction induced by medications, viral infections, autoimmune diseases, and pregnancy
    - anti-platelet Abs bind to platelet surface → increased splenic clearance
    - helper T-cell and cytotoxic T-cell activation
- impaired platelet production
  - myelosuppression mediated by cytotoxic chemotherapy
  - drug induced megakaryocyte suppression

Clinical Features
- variable presentation: asymptomatic, fatigue, minimal bruising, mucocutaneous bleed (e.g. purpura, ecchymoses, petechiae, continuous epistaxis, menorrhagia) most common but bleeding can occur anywhere including intracranial hemorrhage
- assess for symptoms/signs suggesting a secondary cause

Investigations
- CBC: platelet count <100 x 10^9/L
- PT and PTT: normal
- peripheral blood film: decreased platelets ± large platelets (rule out platelet clumping)
- HIV, HCV
- depending on clinical suspicion: *H. pylori* testing (urea breath test, stool antigen, or endoscopy) vitamin B_{12}, ANA, C3, C4, APLA, quantitative immunoglobulins (to rule out underlying immunodeficiency) depending on clinical symptoms
- blood group RhD typing
- BM aspirate and biopsy: increased number of megakaryocytes
  - BM aspirate and biopsy should be considered pre-splenectomy to confirm diagnosis or if there is suspicion of diminished BM function (systemic symptoms, refractory ITP and/or abnormal blood film)

Treatment
- rarely indicated if platelets >30 x 10^9/L unless active bleeding, trauma, or surgery
- emergency treatment (active bleeding (CNS, GI, or GU) or in need of emergency surgery)
  - general measures: stop antiplatelet medications, control blood pressure, minimize trauma
  - corticosteroids: prednisone (0.5-2 mg/kg/d) or dexamethasone (40 mg PO once daily x 4 d)
  - if corticosteroids contraindicated: IVIg 1 g/kg x 1 dose, to be repeated if necessary (raises platelet count faster than corticosteroids)
  - IVIg can be used with corticosteroids when a more rapid increase in platelet count is required
  - antifibrinolytic: tranexamic acid (1 g PO TID or 1 g IV q8 h) if mucosal bleeding
  - platelet transfusion: for refractory, major bleeding, or need for urgent surgery (expect that platelet recovery will be diminished)
  - management of life threatening bleeding (i.e.intracranial bleeding): IV steroids, IVIg, platelet transfusion, may also consider emergency splenectomy -vaccinations prior if possible (*S. pneumoniae, N. meningitidis*, and *H. influenzae* type b)
  - management of intracranial bleeding: IV steroids, IVIg, platelet transfusion
- non-urgent treatment (platelet count <20-30 x 10^9/L and no bleeding)
  - 1st-line
    - corticosteroids (dexamethasone 40 mg PO once daily x 4 d x 1-4 cycles (not wk) or prednisone (0.5-2 mg/kg/d) x 2-3 wk then slow taper over 6 wk)
    - IVIg 1 g/kg
    - anti-D: appropriate for Rh+ non-splenectomized patients, but can cause transient hemolysis (avoid if low Hb at baseline or if DAT is positive)
  - 2nd-line
    - splenectomy (need vaccinations prior to splenectomy: *S. pneumoniae, N. meningitidis*, and *H. influenzae* type b) – not preferred if within 12 mo from diagnosis
    - thrombopoietin (TPO) receptor agonists (romiplostim, eltrombopag) – may not be accessible as second line due to funding considerations
    - rituximab
  - 3rd-line
    - immunomodulating therapy (azathioprine, cyclophosphamide, danazol, and vincristine)
      - may be considered as defacto second line due to funding considerations and access limitations to other treatments
    - Syk inhibitors (Fostamatinib) - blocks platelet clearance

Definitions of Response to Treatment
- complete response: platelet count >100 x 10^9/L
- partial response: platelet count 30-100 x 10^9/L
- no response: platelet count <30 x 10^9/L

Prognosis

- ~20% will not attain a hemostatic platelet count after first and second line therapy
- fluctuating course
- life expectancy similar to general population (however, risk of mortality from bleeding/infection increases with advancing age)
- major concern is spontaneous intracranial hemorrhage, more common in the elderly

Table 22. Heparin-Induced Thrombocytopenia (HIT)

Pathophysiology	Immune mediated Ab recognizes a complex of heparin and platelet factor 4 leading to platelet activation via platelet Fc receptor and activation of coagulation system
Diagnosis	Suspected with intermediate or high probability HIT score Screen with immunoassays (e.g. HIT ELISA) and confirm with functional testing (Serotonin Release Assay)
Onset of Decreased Platelets	5-14 d (if previously exposed to heparin within 100 d, HIT can develop in hours due to an anamnestic response)
Risk of Thrombosis	30-50% (25% of events are arterial) if untreated
Clinical Features	Bleeding complications uncommon Venous thrombosis: DVT, PE, limb gangrene, cerebral venous sinus thrombosis Arterial thrombosis: MI, stroke, acute limb ischemia, organ infarct (mesentery, kidney) Heparin-induced skin necrosis (with LMWH) Non-necrotizing erythematous skin lesions Acute platelet activation syndromes: acute inflammatory reactions (e.g. fever/chills, flushing, etc.)
Specific Tests	Pre-test clinical scoring models can help rule-out HIT: 4Ts and the HIT Expert Probability (HEP) score 14C serotonin release assay (tests the functional ability of patient's plasma to activate platelets) ELISA for HIT-Ig (more sensitive, less specific than serotonin assay, faster turnaround time, high negative predictive value) Ultrasound of lower limb veins and upper extremity with central venous catheter for DVT
Management	Clinical suspicion of HIT should prompt discontinuation of UFH and LMWH including flushes (specific tests take several days) Initiate anticoagulation with a non-heparin anticoagulant: e.g. argatroban, danaparoid, fondaparinux, bivalirudin unless there is a strong contraindication (duration depends on presence or absence of thrombosis) warfarin should be started when platelet count >150 x 10^9/L DOACs can be started before platelet count recovery Allergy band and alert in patient records

Table 23. The 4T Pre-Test Clinical Scoring Model for HIT

Category	2 Points	1 Point	0 Points
Thrombocytopenia	Platelet count fall >50% AND platelet nadir ≥20 x 10^9/L	Platelet count fall 30-50% OR platelet nadir 10-19 x 10^9/L	Platelet count fall <30% OR platelet nadir <10 x 10^9/L
Timing of Platelet Count Fall	Clear onset between 5-10 d of heparin exposure OR platelet count fall at ≤1 d if prior heparin exposure within last 30 d	Consistent with fall in platelet count at 5-10 d but unclear (e.g. missing platelet counts) OR onset after 10 d OR fall ≤1 d with prior heparin exposure within 30-100 d	Platelet count fall after ≤4 d of heparin exposure, and no recent heparin
Thrombosis or Other Sequelae	Confirmed new thrombosis, skin necrosis, or acute systemic reaction after IV unfractionated heparin bolus, adrenal hemorrhage	Progressive or recurrent thrombosis, non-necrotizing (erythematous) skin lesions, or suspected thrombosis that has not been proven	None
Other Causes for Thrombocytopenia	None apparent	Possible	Definite

6-8 points = high probability of HIT; 4-5 points = intermediate probability of HIT; 0-3 points = low probability of HIT

Cuker A, Arepally GM, Chong BH, et al. American Society of Hematology 2018 guidelines for management of venous thromboembolism: heparin-induced thrombocytopenia. Blood Adv. 2018;2:3360-3392

Heparin-induced thrombocytopenia (previously known as HIT type II): immune-mediated reaction following treatment with heparin leading to platelet activation and subsequent coagulation activation
Heparin-associated thrombocytopenia (previously known as HIT type I): transient thrombocytopenia following administration of heparin

Heparin-Associated Thrombocytopenia (previously known as HIT type I)

- Direct heparin mediated platelet aggregation (non-immune)
- Platelets >100 X 10^9/L
- Self-limited (no thrombotic risk)
- May continue with heparin therapy
- Onset 24-72 h

LMWH is also associated with HIT, but the risk is less than unfractionated heparin (2.6% in UFH vs. 0.2% in LMWH)

American Society of Hematology Choosing Wisely Recommendation
Don't test or treat for HIT in patients with low pre-test probability of HIT (4T's score of 0-3) as HIT can be excluded
Do not discontinue heparin or start a non-heparin anticoagulant in these low-risk patients because of increased risk of bleeding and increased cost of alternatives

Thrombotic Microangiopathies (TMAs)

Definition

- thrombotic disorder characterized by thrombi formation in small blood vessels
- TTP, HUS, and aHUS are examples of TMAs

Table 24. TTP and HUS

	TTP	HUS (see Pediatrics, P82)
Epidemiology	Immune form presents predominantly in adults Congenital form presents predominantly in children	Predominantly children and elderly
Etiology	Deficiency of ADAMTS13: metalloproteinase that breaks down ultra-large VWF multimers Congenital (genetic absence of ADAMTS13) Acquired (drugs, malignancy, transplant, HIV-associated, and idiopathic)	Shiga toxin (*E. coli* serotype 0157:H7) in 90% Other bacteria, viruses, genetic causes, and drugs
Clinical Features	1. Thrombocytopenia 2. MAHA/TMA 3. Neurological symptoms: headache, confusion, focal defects, and seizures 4. Symptoms can be mild and non-specific	1. Severe thrombocytopenia 2. MAHA/TMA 3. Acute kidney injury 4. Bloody diarrhea 5. GI prodrome
Investigations (both TTP, HUS)	CBC and blood film: decreased platelets and increased schistocytes PT, PTT, fibrinogen: normal Markers of hemolysis: increased unconjugated bilirubin, increased LDH, and decreased haptoglobin Negative Coombs test/DAT Creatinine and urea to follow renal function (kidney injury is uncommon in TTP vs. HUS induces severe injury that is sudden in onset) ADAMTS13 gene, activity or inhibitor testing (TTP)	
Management	Medical emergency: TTP mortality ~90% if untreated Plasma exchange ± steroids Platelet transfusion avoided unless life-threatening bleed (associated with microvascular thrombosis) Plasma infusion if plasmapheresis is not immediately available Caplacizumab in certain cases of acquired TTP	Supportive therapy (fluids, RBC transfusion, nutrition, etc.) Some evidence for plasma exchange Possible role of eculizumab (C5 Ab blocks complement activation) for neurologic symptoms

Note: aHUS is a complex disease with different etiology, treatment depends on genetic abnormalities

Pathophysiology of TTP

- Normally, large VWF multimers secreted by endothelial cells are rapidly cleaved by ADAMTS13 protease
- Congenital TTP is due to a genetic deficiency in ADAMTS13
- Acquired TTP (the more common form) is due to Abs against ADAMTS13
- Without ADAMTS13, uncleaved VWF continues to promote platelet adhesion, causing excess platelet aggregation in small blood vessels

Differential Diagnosis of TTP

DIC
HUS
aHUS
HELLP
Catastrophic APS
Evans syndrome (AIHA + ITP)

von Willebrand Disease

Definition

- bleeding disorder characterized by impaired clot formation due to qualitative or quantitative deficiencies in VWF

Pathophysiology

- most common inherited bleeding disorder (prevalence of 1%)
- usually autosomal dominant (types 2N and 3 are autosomal recessive)
- women more commonly diagnosed (heavy menstrual bleeding, peripartum bleeding)
- qualitative defect or quantitative deficiency of VWF depending on type
  - VWF mediates platelet adhesion/aggregation and acts as a chaperone for Factor VIII (extending its half-life in circulation); abnormal VWF can affect both primary and secondary hemostasis
  - VWF exists as a series of multimers ranging in size
    - largest multimers are most active in mediation of platelet adhesion/aggregation
    - both large and small multimers complex with Factor VIII
    - VWF levels vary according to blood group (lowest in group O patients) and other factors (higher with pregnancy, hormonal medication, acute inflammation)

Classification

- type 1: mild quantitative deficiency (decreased amount of VWF and proportional decrease in VWF activity) – 80% of cases
- type 2: qualitative defect (VWF activity disproportionally lower than quantity) – 20% of cases
  - type 2A: reduced VWF-dependent platelet adhesion due to high and intermediate molecular weight VWF multimer deficiency
  - type 2B: increased affinity for platelet GPIb and subsequent loss of high and intermediate molecular weight VWF multimers
  - type 2M: reduced VWF-dependent platelet adhesion with normal VWF multimer levels
  - type 2N: decreased affinity for Factor VIII
- type 3: severe total quantitative defect (virtually no VWF produced) – 1 in 1000000

Clinical Features

- bleeding history is the single most important predictor of an underlying bleeding disorder
- validated, standardized bleeding assessment tools (e.g. ISTH-BAT) to facilitate exploration of the bleeding history
- mucocutaneous bleeding (easy bruising, epistaxis (>10 min), heavy menstrual bleeding, peripartum bleeding, post-dental extraction bleeding, excessive postoperative bleeding, and unexplained gastrointestinal bleeding)

  - type 3 VWD patients can experience musculoskeletal bleeding due to significant deficiency in Factor VIII (lack of Factor VIII chaperoning as VWF is absent)
- family history of a bleeding disorder (a negative family history cannot be used to exclude the diagnosis)

Investigations
- CBC, platelet, VWF antigen (determine how much VWF is present), VWF ristocetin cofactor activity (determine how well VWF binds to platelet), Factor VIII (determine how well VWF chaperones Factor VIII), and PTT
- tests to further categorize type/subtype of VWD: multimer analysis, ristocetin induced platelet agglutination, and genetic studies

Table 25. Investigations in VWD

Test	Expected Result
PTT	N/↑
Plt Count	N/↓ (can be low in type 2B)
Blood group	Affects antigen quantification (↓ in group O)
Ferritin	Rule out secondary iron deficiency due to bleeding
von Willebrand antigen	↓
Ristocetin activity	↓ (cofactor for VWF-Plt binding)
Factor VIII	N/↓
VWF multimer analysis	Multimer variants

Consider VWD in all women with heavy menstrual bleeding

VWD is the most common heritable bleeding disorder

Treatment
- DDAVP® is effective treatment for 85-90% of patients with type 1 VWD and for some subtypes of type 2 VWD
  - causes release of VWF and Factor VIII from endothelial cells
  - variable efficacy depending on disease type; tachyphylaxis occurs after 4 consecutive doses
  - need to document responsiveness with "DDAVP® challenge"
  - caution in children due to hyponatremia
- tranexamic acid (Cyklokapron®, antifibrinolytic) to stabilize clot formation
- VWF:Factor VIII concentrate (Humate P®, Wilate®) if DDAVP® unresponsive/clinically ineffective or for severe bleeding episode
  - need to monitor VWF and factor VIII levels (very high factor VIII level can be prothrombotic)
- gynecologic focused care for heavy menstrual bleeding (N.B. estrogens have the added benefit of increasing VWF levels)

Prognosis
- patients with mild type 1 VWD usually have auto-correction of VWF deficiency in pregnancy
- most cases are mild-moderate, and only ~10% of cases require long-term prophylactic therapy

Disorders of Secondary Hemostasis/Fibrinolysis

Definition
- inability to form an adequate fibrin clot
  - disorders of coagulation factors or cofactors
  - disorders of proteins associated with fibrinolysis
- patients can experience bleeding anywhere in the body but delayed bleeding, deep muscular bleeding, and spontaneous hemarthroses are highly suggestive of disorders of secondary hemostasis/fibrinolysis

Table 26. Classification of Secondary Hemostasis Disorders

Hereditary	Acquired
Factor VIII deficiency: Hemophilia A, VWD	Liver disease
Factor IX deficiency: Hemophilia B (Christmas Disease)	DIC
Factor XI deficiency: Hemophilia C	Vitamin K deficiency
Other factor deficiencies are rare	Acquired inhibitors (Factor VIII most common)

Hemophilia A (Factor VIII Deficiency)

Pathophysiology
- X-linked recessive disorder where factor VIII is absent or deficient, 1 in 5000 males
- mild (>5% of normal factor level), moderate (1-5%), severe (<1%)

Clinical Features
see *Table 19, H27* under secondary coagulation
- patients may have also acquired HIV or HCV from contaminated blood products (no cases observed from transfusions in Canada since 1985)

Investigations
- CBC
- prolonged PTT, normal INR (PT)
- decreased factor VIII (<40% of normal)
- VWF antigen and ristocetin activity testing to rule out VWD

Treatment
- DDAVP® in mild hemophilia A
- factor VIII concentrate for:
  - prophylaxis (recommended for patients with severe hemophilia A)
  - on-demand (i.e. to treat a bleed)
- antifibrinolytic agents (e.g. tranexamic acid), especially for mucosal bleeds

Hemophilia B (Factor IX Deficiency)

- X-linked recessive, 1 in 30000 males; approximately half have severe disease (factor IX activity <1% of normal)
- clinical and laboratory features identical to hemophilia A (except deficiency in factor IX instead of factor VIII)
- treatment: factor IX concentrate (prophylaxis or on-demand), antifibrinolytic agents

Factor XI Deficiency

- autosomal recessive; more common in Ashkenazi Jewish population
- usually mild (severe spontaneous bleeding is rare), often diagnosed in adulthood following bleeding challenge (e.g. surgery)
- factor XI level does not correlate proportionally with bleeding risk – risk of bleeding correlates with a previous history or family history of bleeding
- treatment: antifibrinolytic agents, FP, Factor XI concentrate, DDAVP®

Liver Disease

- see Gastroenterology, G32

Pathophysiology
- thrombocytopenia secondary to: hypersplenism, nutritional deficiency, direct BM toxicity related to alcohol, diminished production from chronic viral infections (e.g. HCV), and decreased production of TPO
- deficiency in synthesis of all factors except VIII (also made in endothelium)
- aberrant or diminished synthesis of fibrinogen (factor I)
- diminished synthesis of natural anticoagulants and altered regulation of fibrinolysis

Investigations
- CBC, peripheral blood film: thrombocytopenia, target cells
- primary hemostasis affected
  - thrombocytopenia
- secondary hemostasis affected
  - elevated INR (PT), PTT, TT
  - low fibrinogen in end-stage liver disease

Investigations in Liver Disease
Factor V, VII, VIII. Expect decreased V and VII because they have the shortest half-life. Factor VIII will be normal or increased because it is produced in the endothelium

Treatment
- supportive, treat liver disease, blood products if active bleeding (FP, platelets, cryoprecipitate)

Vitamin K Deficiency

Etiology
- drugs
  - vitamin K antagonist (e.g. warfarin) – diminished production of functional Factors II, VII, IX, X, proteins C and S
  - antibiotics eradicating gut flora, altering vitamin K uptake
- poor diet: e.g. prolonged fasting or starvation (especially due to chronic alcohol consumption)
- biliary obstruction
- chronic liver disease (decreased stores)
- fat malabsorption (e.g. celiac disease, disorders of bile or pancreatic secretion, intestinal disease, and cystic fibrosis)

Vitamin K Dependent Factors
Vitamin K antagonists (e.g. warfarin) affect function of these factors:
"**1972** **C**anada vs. **S**oviets"
X, IX, VII, II, proteins **C** and **S**

PT should improve within 24 h of adequately dosed vitamin K repletion (onset is in 6-12 h); if not, search for other causes

Investigations
- INR (PT) is elevated out of proportion to elevation of the PTT
- decreased Factors II, VII, IX, X (vitamin K-dependent)

Treatment
- hold anticoagulant if vitamin K antagonist on board
- vitamin K PO if no active bleeding
- if bleeding, give vitamin K 10 mg IV (reversal may take up to 12 h)
- if life-threatening bleeding and vitamin K antagonist used, give PCC or FP if PCC contraindicated
  - PCCs are relatively contraindicated in liver disease or if there is a previous history of HIT (PCC product contains heparin)

American Society of Hematology Choosing Wisely Recommendation
Do not administer plasma or prothrombin complex concentrates for non-emergent reversal of vitamin K antagonists (e.g. outside of the setting of major bleeding, intracranial hemorrhage, or anticipated emergent surgery)

Disseminated Intravascular Coagulation

Definition
- excessive, dysregulated release of plasmin and thrombin leading to intravascular coagulation and fibrinolysis
- depletion of platelets, coagulation factors, and fibrinogen
- risk of life-threatening hemorrhage and/or thrombosis

Etiology
- occurs as a complication of many other severe medical, surgical, or obstetrical conditions
- widespread endothelial damage and extensive inflammatory cytokine release

DIC is a spectrum which may include thrombosis, bleeding, or both

Clinical Features
- presence of both hemorrhage and clotting

Table 27. Clinical Features of DIC

Signs of Microvascular Thrombosis	Signs of Hemorrhagic Diathesis
Neurological: multifocal infarcts, delirium, coma, seizures **Skin:** focal ischemia, superficial gangrene, purpura fulminans **Renal:** oliguria, azotemia, cortical necrosis **Pulmonary:** ARDS **GI:** acute ulceration, liver dysfunction **Adrenal failure:** adrenal hemorrhage or infarction **RBC:** microangiopathic hemolysis (schistocytes)	**General:** Bleeding from any site in the body (secondary to decreased platelets and coagulation factors) **Neurologic:** intracranial bleeding **Skin:** petechiae, ecchymosis, oozing from puncture sites **Renal:** hematuria **Mucosal:** gingival oozing, epistaxis, massive bleeding

Factor Levels in Acquired Coagulopathies

Factor	Liver Disease	Vitamin K Def	DIC
V	↓	N	↓
VII	↓	↓	↓
VIII	N/↑	N	↓

Important Etiologies of DIC

OMITS
Obstetric complications
Malignancy
Infection
Trauma
Shock

Investigations
- peripheral blood smear: schistocytes
- primary hemostasis: CBC, decreased platelets
- secondary hemostasis: prolonged INR (PT), PTT, TT, decreased fibrinogen and other factors
- accelerated fibrinolysis: increased FDPs or D-dimers and short euglobulin lysis time

Treatment
- individualize supportive therapy according to underlying condition: recognize early and treat underlying disorder – supportive measures: hemodynamic and/or ventilator support, aggressive hydration, and RBC transfusion if severe bleed
- in bleeding phase (recommendations from ISTH Guidance Statement 2013):
  - treat the underlying condition
  - transfuse platelets in patients with active bleeding if platelet count <50 x 10^9/L or in those with a high-risk of bleeding and a platelet count of <20 x 10^9/L
  - FP may be useful in patients with active bleeding with either prolonged PT/aPTT (>1.5 times normal). FP should be considered in DIC patients requiring an invasive procedure with similar laboratory abnormalities
  - fibrinogen concentrate or cryoprecipitate may be recommended in actively bleeding patients with persisting severe hypofibrinogenemia (<1.5 g/L)
  - PCC may be considered in actively bleeding patients if FP transfusion is not possible
- in thrombotic phase:
  - LMWH preferred over UFH in critically ill, non-bleeding patients

Clinical Prediction of DIC - International Society of Thrombosis and Hemostasis (ISTH) Calculator
Presence of an underlying, predisposing condition is a requirement

DIC diagnosis is defined as ≥5 points

Points	0	1	2	3
Platelet count x 10^9/L	>100	50-100	<50	
Level of Fibrin markers (D-dimer or FDP)	No increase		Moderate increase <5 x ULN	Strong increase ≥5 x ULN
Prolonged PT (s)	<3	≥3-6	≥6	
Fibrinogen (g/L)	>1.0	≤1.0		

Table 28. Differential Diagnosis for Abnormal Coagulation Testing

Increased PT/INR Only	Increased PTT Only	Both Increased
Warfarin Vitamin K deficiency Factor VII deficiency Liver disease Factor VII inhibitors	Intrinsic factor deficiency: Factor VIII (Hemophilia A), Factor IX (Hemophilia B), Factor XI, Factor XII Heparin, DOACs Antiphospholipid Ab Intrinsic factor inhibitors (e.g. Factor VIII)	Deficiency of common pathway factors: Prothrombin (Factor II), fibrinogen, Factor V, Factor X Severe liver disease Factor V, Factor X, prothrombin, and fibrinogen inhibitors Excessive anticoagulation Severe vitamin K deficiency

Hypercoagulable Disorders

Hypercoagulability Workup – Venous Thrombosis

- workup for hypercoagulable state should be considered *ONLY* if it will alter treatment decisions
- includes inherited or acquired thrombophilia
  - hypercoagulability workup may be considered in patients with:
    - multiple recurrent thromboses
    - warfarin-induced skin necrosis or neonatal purpura fulminans (protein C or S deficiency)
    - thrombosis at an unusual venous site
    - abnormal blood work, constitutional symptoms, or physical exam findings suggestive of cancer
  - arterial thrombotic events due to a hypercoagulable state are typically associated with APS, HIT, JAK2+ MPNs, and PNH, not hereditary thrombophilias
- workup (if indicated)
  - initial
    - CBC, blood smear, coagulation studies, liver/renal function tests, urinalysis, and hemolysis markers (if anemic)
    - malignancy history, age appropriate cancer screening
    - serology: APLA (lupus anticoagulant will be affected by anticoagulation)
    - depending on CBC, consider JAK2
  - post-treatment (or ≥6 wk, as protein levels are depleted/consumed by clot and can be affected by anticoagulation)
    - antithrombin activity
    - proteins C, S activity
- note: most of these tests do not change management, and a negative test does not rule out a hypercoagulable state
- decision to pursue hypercoagulability workup should be made in consultation with a hematologist

SELECTED CAUSES OF HYPERCOAGULABILITY

Factor V Leiden (Activated Protein C Resistance)

- most common cause of hereditary thrombophilia
- 3-7% of European White population are heterozygotes
- point mutation in the Factor V gene (R506Q) results in resistance to inactivation of Factor Va by activated protein C

Prothrombin Gene Mutation (PT) G20210A

- 1-3% of European White population are heterozygotes
- G to A transposition at nucleotide position 20210 of the prothrombin gene promoter region results in increased levels of prothrombin, thus increased thrombin generation

Protein C and Protein S Deficiency

- protein C inactivates Factors Va and VIIIa using protein S as a cofactor
- protein C deficiency
  - homozygous or compound heterozygous: neonatal purpura fulminans
  - heterozygous
    - type I: decreased protein C levels
    - type II: decreased protein C activity
  - acquired: liver disease, sepsis, DIC, warfarin, and certain chemotherapeutic agents
  - 1/3 of patients with warfarin necrosis have underlying protein C deficiency
- protein S deficiency
  - type I: decreased free and total protein S levels
  - type II: decreased protein S activity
  - type III: decreased free protein S levels
  - acquired: liver disease, DIC, pregnancy, nephrotic syndrome, inflammatory conditions, and warfarin

Antithrombin Deficiency

- antithrombin slowly inactivates thrombin, a process accelerated by heparin
- causes/etiology: autosomal dominant inheritance, urinary losses in nephrotic syndrome, or reduced synthesis in liver disease
- diagnosis must be made outside window of acute thrombosis and anticoagulation treatment (acute thrombosis, heparin, systemic disease all decrease antithrombin levels)
- deficiency may result in resistance to UFH (LMWH may be considered, with monitoring of anti-Xa levels)
  - heparin resistance: suspect if >35000 IU of UFH required during 24 h use

Elevated Factor VIII Levels

- an independent marker of increased incident and recurrent thrombotic risk, but levels can also be increased in numerous states as an acute phase reactant, therefore its clinical use is controversial

Differential Diagnosis of Elevated D-Dimer

- Arterial thromboembolic disease (e.g. MI, cerebrovascular accident, acute limb ischemia, AFib, intracardiac thrombus)
- Venous thromboembolic disease (e.g. DVT, PE)
- Abnormal fibrinolysis (e.g. use of thrombolytic agents)
- Surgery/trauma (e.g. tissue ischemia, necrosis)
- Vaso-occlusive episode of SCD
- Renal disease (nephrotic syndrome, acute/chronic renal failure)
- Pregnancy-related (e.g. normal pregnancy, preeclampsia, eclampsia)
- Cardiovascular-related (e.g. cardiovascular disease, CHF)
- Severe infection/sepsis/inflammation, systemic inflammatory response syndrome
- DIC
- Malignancy
- Severe liver disease
- Venous malformation

Isolated prolonged INR is most commonly due to Factor VII deficiency in the extrinsic pathway since it has the shortest half-life
Isolated elevated PTT is usually due to factor deficiency or inhibitors in the intrinsic pathway

American Society of Hematology Choosing Wisely Recommendations

1. Do not test for thrombophilia in adult patients with venous thromboembolism occurring in the setting of major transient risk factors (i.e. surgery, trauma, or prolonged immobility)
2. Do not use inferior vena cava filters routinely in patients with acute venous thromboembolism

Common Causes of Hypercoagulability

CALM APES
Protein **C** deficiency
APS
Factor **V** Leiden
Malignancy
Antithrombin deficiency
Prothrombin G20210A
Increased Factor **VIII** (**E**ight)
Protein **S** deficiency

Causes of Both Venous and Arterial Thrombosis include:
APS
MPN
HIT
Distal venous clot with patent foramen ovale
PNH

Protein C, protein S, and ATIII are decreased during acute thrombosis – therefore to test for deficiency, they must be tested outside of this time period

Congenital Dysfibrinogenemia
- may predispose to thromboembolic disease, bleeding, or both

Disorders of Fibrinolysis
- includes congenital plasminogen deficiency, and tPA deficiency, but association with VTE risk is not clear

Antiphospholipid Antibody Syndrome
- definition: ≥1 clinical and ≥1 laboratory criteria
  - clinical: arterial or venous thrombosis, recurrent (>3) early pregnancy losses <10 wk, one late fetal loss ≥10 wk (morphologically normal), or premature birth before 34 wk due to (pre)eclampsia or placental insufficiency
  - laboratory (must be confirmed on two occasions, tested ≥12 wk apart): anticardiolipin IgG and IgM, anti-β2 glycoprotein-I Ab, or lupus anticoagulant
- mechanism: not well understood, Abs interact with platelet membrane phospholipids causing increased activation; can also interfere with thrombin regulation, fibrinolysis, and inhibit the protein C pathway
- see Rheumatology, RH13

Venous Thromboembolism

Definition
- thrombus formation and subsequent inflammatory response in a superficial or deep vein
- includes superficial vein thrombosis , DVT, and PE
- thrombi propagate in the direction of blood flow (commonly originating in calf veins)
- DVT is more common in lower extremity than upper extremity (upper extremity DVT are increasing due to more central venous access lines)
- incidence ~1% if age >60 yr
- most important sequelae of DVT are PE (~50% chance with proximal DVT) and post thrombotic syndrome (chronic venous insufficiency)
- acutely, PE can result in cardiorespiratory failure and death (rare in treated patients). Most severe chronic sequela of PE is chronic thromboembolic pulmonary hypertension (CTEPH)

Etiology (Virchow's Triad)
- endothelial damage
  - exposure of procoagulant proteins on dysfunctional endothelium promotes thrombosis
  - decreased inhibition of coagulation and local fibrinolysis
  - changes to vessel wall integrity may result in turbulent blood flow
- venous stasis
  - immobilization (e.g. post-MI, CHF, stroke, and postoperative) inhibits clearance and dilution of coagulation factors
- hypercoagulability
  - inherited (see *Hypercoagulable Disorders, H35*)
  - acquired
  - age (risk increases with age)
  - surgery (especially orthopedic, thoracic, GI, and GU)
  - trauma (especially fractures of spine, pelvis, femur, or tibia, and spinal cord injury)
  - neoplasms (especially pancreas, stomach, lung, lymphoma, bladder, testicular, colorectal, and gynecologic - based on the Khorana score)
  - blood dyscrasias (MPNs, especially PV, ET), PNH, hyperviscosity (multiple myeloma, polycythemia, leukemia, and SCD), hemolytic anemias
  - prolonged immobilization (e.g. CHF, stroke, MI, and leg injury)
  - hormone related (combined OCP, hormone replacement therapy, and selective estrogen receptor modulators)
  - pregnancy
  - APS
  - heart failure (risk of DVT greatest with right heart failure and peripheral edema)
    - New York Heart Association (NYHA) Class III and IV
- idiopathic (10-20% are later found to have cancer)

Clinical Features of DVT
- absence of physical findings does not rule out disease
- unilateral leg edema, erythema, warmth, and tenderness; purple-blue colour may indicate severe limb-threatening thrombus
- palpable cord (i.e. thrombosed vein)
- phlegmasia alba dolens (white appearance) and phlegmasia cerula dolens (acute pain and edema) with massive thrombosis
- Homan's sign (pain or resistance with foot dorsiflexion) is unreliable

Differential Diagnosis of DVT
- muscle strain or tear, lymphangitis or lymph obstruction, venous valvular insufficiency, ruptured popliteal cysts, cellulitis, and arterial occlusive disease

Malignancy is a Common Cause of Acquired Hypercoagulability

Workup should include:
Complete history and physical
Age appropriate screening:
Mammogram, Pap, PSA, colonoscopy
Additional imaging/laboratory testing based on clinical suspicion
Close follow-up

Screening for Occult Cancer in Unprovoked VTE (SOME)
NEJM 2015;373:697-704
Purpose: To assess the efficacy of a screening program for occult cancer that employs CT of the abdomen and pelvis in patients experiencing their first unprovoked episode of VTE.
Methods: Patients (n=854) were randomly assigned to limited occult-cancer screening or limited occult-cancer screening plus CT.
Results: 3.2% of patients in the limited-screening group and 4.5% of patients in the limited-screening plus CT group received a new diagnosis of occult cancer between the randomization point and 1-year followup (P=0.28). Four occult cancers were missed by the limited screening strategy, while five occult cancers were missed by the limited screening plus CT strategy (P=1.0).
Conclusion: Routine screening with CT in patients who had a first unprovoked VTE did not provide a clinically significant benefit.

Although lupus anticoagulant prolongs PTT, this is a misnomer, as its main clinical feature is thrombosis

Risk of VTE in Hospitalized Patients Receiving Ineffective Antithrombotic Therapy

Risk Factor	RR (95% CI)	P-value
Age >75 yr	1.79 (1.18-2.71)	0.007
Cancer	1.58 (1.01-2.51)	
Previous VTE	1.67 (1.01-2.77)	0.08
Obesity	0.94 (0.59-1.51)	0.91
Hormone therapy	0.51 (0.08-3.38)	0.70
Heart failure	1.08 (0.72-1.62)	0.82
NYHA III	0.89 (0.55-1.43)	0.72
NYHA IV	1.48 (0.84-2.6)	0.27
Acute infectious disease	1.50 (1.00-2.26)	0.06
Acute rheumatic disease	1.45 (0.84-2.50)	0.27

Source: JAMA 2004;164:963-968

Virchow's Triad
Endothelial damage
Blood stasis
Hypercoagulability

Investigations for DVT
- D-dimer test only useful to rule out DVT if negative with low clinical suspicion of disease (Modified Wells' Pre-test Probability ≤1) and no other acute medical issues; positive result may be non-specific
- doppler ultrasound is most useful diagnostic test for DVT
  - sensitivity and specificity for proximal DVT ~95%
  - sensitivity for calf DVT ~70%
- venography is the gold standard, but is expensive, invasive, and higher risk
- CT pulmonary angiogram or V/Q scan if PE suspected

Post-Thrombotic Syndrome
- development of chronic venous stasis signs and symptoms secondary to a deep venous thrombosis
- symptoms: pain, venous dilatation, edema, pigmentation, skin changes, and venous ulcers
- clinical severity can be assessed using the Villalta score
- large impact on quality of life following a DVT
- treatment: extremity elevation, exercise, compression stockings, and skin/ulcer care
- for clinical features and treatment of PE, see Respirology, R20

Approach to Treatment of Venous Thromboembolism

Purpose
- prevent further clot extension (minimum 3 mo duration)
- prevent acute PE (occurs in up to 50% of untreated patients)
- reduce the risk of recurrent thrombosis (duration depends on presence of other risk factors)
- treatment of massive iliofemoral thrombosis with acute lower limb ischemia and/or venous gangrene (phlegmasia cerulea dolens)
- limit development of late complications (e.g. post-thrombotic syndrome, chronic venous insufficiency, and chronic thromboembolic pulmonary HTN)

Initial Treatment
- consider empiric treatment in patient with moderate/high suspicion of DVT and low-risk of bleeding, if diagnostic imaging will be delayed (definitive imaging should be obtained at first opportunity)
- DOACs
  - apixaban or rivaroxaban alone (with loading dose)
  - dabigatran or edoxaban require 5-10 d of parenteral anticoagulation (usually LMWH) prior to initiation
  - contraindications: during conception/pregnancy, and in breastfeeding women
  - there remains limited evidence in severe renal deficiency and some clinicians do not use DOACs in this population
- LMWH
  - administered SC, at least as effective as UFH with a lower bleeding risk
  - advantages: predictable dose response and fixed dosing schedule, lab monitoring not required, <1% HIT, safe and effective outpatient therapy (including pregnant and cancer patients)
  - disadvantages: only partially reversible by protamine, long-term use associated with osteoporosis
  - renally cleared – may require dose adjustment in patients with renal dysfunction
- UFH
  - in patients with high-risk of bleed, or requiring rapid interruption for surgical procedures; use hospital-based nomograms that use bleeding risk and patient weight to determine appropriate dose
  - advantages: rapidly reversible by protamine
  - disadvantages: must monitor aPTT or heparin levels with adjustment of dose to reach therapeutic level (~2x normal value); higher risk for development of HIT

Long-Term Oral Treatment
- anticoagulation therapy
  - warfarin
    - should be initiated with heparin overlap: dual therapy for at least 48 h with INR >2, due to initial prothrombotic state (secondary to warfarin's inhibition of natural anticoagulants protein C/S), half-life of vitamin K factors and risk of warfarin-induced skin necrosis
    - dosed to maintain INR at 2-3, monitor twice weekly for 1-2 wk
    - discontinue heparin after INR >2.0 for 2 consecutive days
  - DOACs
    - apixaban or rivaroxaban: INR not used, patients with CrCl >15 mL/min
    - dabigatran (factor IIa inhibitor) or edoxaban: LMWH or IV heparin for at least 5 d before initiating dabigatran, INR not used, patients with CrCl >15 mL/min (Edoxaban) and >30 mL/min (Dabigatran)
    - important drug interactions to consider for DOACs: inducers or inhibitors of CYP3A4 or P-gp
    - cancer patients: LMWH more effective than warfarin at preventing recurrence of venous thrombosis in cancer patients; DOACs are as effective as LMWH (more bleeding observed for patients with GI cancer taking rivaroxaban or edoxaban)

Wells' Score for Predicting DVT
- Paralysis, paresis, or recent orthopedic casting of lower extremity (1)
- Recently bedridden (>3 d) or major surgery within past 4 wk (1)
- Localized tenderness in deep vein system (1)
- Swelling of entire leg (1)
- Calf swelling >3 cm compared to the other leg (measured 10 cm below the tibial tuberosity) (1)
- Pitting edema greater in the symptomatic leg (1)
- Collateral non-varicose superficial veins (1)
- Active cancer or cancer treated within 6 mo (1)
- Alternative diagnosis more likely than DVT (e.g. Baker's cyst, cellulitis, muscle damage, superficial venous thrombosis) (-2)

Total Score Interpretation
3-8: High probability, 1-2: Moderate probability, -2-0: Low probability

Modified Wells' Score
Same as above except with 1 additional point for a history of DVT or major surgery within past 12 wk, and the score interpretation is DVT likely for ≥2 points and DVT unlikely for ≤1 point. D-dimer is ordered for DVT unlikely patients to fully rule out DVT which can help reduce unnecessary ultrasounds

See Landmark Hematology Trials for more information on the CLOT trial. It details the efficacy of low-molecular-weight heparin vs. oral anticoagulant agents in preventing recurrent thrombosis in patients with cancer.

Duration of Treatment with Vitamin K Antagonists (VKA) in Symptomatic Venous Thromboembolism
Cochrane DB Syst Rev 2014;CD001367
Purpose: To evaluate the efficacy and safety of various durations of therapy with VKA in patients with symptomatic VTE.
Study Selection: RCTs comparing various durations of therapy with VKA in patients with symptomatic VTE.
Results: 11 studies (total 3716 participants) were included. A significant reduction in the risk of recurrent VTE was observed during prolonged VKA treatment (RR 0.20, 95% CI, 0.11 to 0.38) independent of the time elapsed since the index thrombotic event. Patients receiving prolonged treatment were at increased risk of bleeding complications (RR 2.60, 95% CI 1.51 to 4.49).
Conclusion: Treatment with VKA strongly reduces the risk of recurrent VTE for as long as they are used. Therapy should be discontinued when the risk of harm from major bleeding (which remains constant over time) is of greater concern than the absolute risk of recurrent VTE (which declines over time).

Common Medications that Interact with Warfarin
Acetaminophen (interference with vitamin K metabolism)
Allopurinol
NSAIDs (GI injury)
Fluconazole
Metronidazole
Sulfamethoxazole
Tamoxifen

- LMWH
  - typically reserved as long term therapy for patients unable to tolerate oral anticoagulants (e.g. unable to absorb oral medications, high risk bleeding patients with intraluminal GI malignancy)
- duration of anticoagulant treatment
  - provoked VTE with transient risk factor: 3 mo
  - provoked VTE with ongoing risk factor: consider indefinite therapy with annual reassessment
  - first unprovoked proximal DVT or PE: ≥3 mo, consider indefinite therapy with annual reassessment
  - second unprovoked VTE: consider indefinite therapy if not already on
  - cancer-associated DVT: consider indefinite therapy for as long as patient has active malignancy (in patients who have cancer in remission, anticoagulation is usually extended for 3-6 mo post last treatment)
  - inferior vena cava filters
  - temporary filter indicated only if acute DVT (<4 wk) with significant contraindications to anticoagulant therapy (i.e. active bleeding) or if anticoagulation must be interrupted (i.e. for urgent surgery)
  - must be retrieved once safe to do so as filter is pro-thrombotic in the long-term and associated with other complications (migration of filter, etc.)
- special considerations
  - pregnancy: treat with LMWH during pregnancy, then LMWH or warfarin for 6 wk post-partum (minimum total anticoagulation time of 3-6 mo, but must include 6 wk post-partum, as this is a high-risk period)
  - avoid warfarin in pregnancy due to teratogenicity outside of select patient populations (e.g. may be used by some thrombosis experts during the second and third trimesters in women with mechanical heart valves)
  - avoid DOAC in conception and pregnancy (due to lack of data) and if breastfeeding in postpartum period
  - surgery: avoid elective surgery in the first 3 mo after a venous thromboembolic event
    - preoperatively: IV heparin may be used up to 4-6 h preoperatively
    - warfarin or DOACs discontinued for at least 2-5 d preoperatively (consider mechanism of drug clearance)
    - postoperatively: IV heparin, LMWH, DOAC can be used for anticoagulation (consult with surgeon prior to re-initiation)
    - for patients at high-risk for thromboembolism (VTE <12 wk, recurrent VTE, APS, AFib with prior stroke, and mechanical heart valve), IV heparin or LMWH (bridging) may be considered before and after the procedure while the INR is below 2.0. Bridging not required for DOACs

In Hospital Prophylaxis

- consider for those with a moderate to high-risk of thrombosis without contraindications
- non-pharmacological measures include: early ambulation, elastic compression stockings (TEDs), and intermittent pneumatic compression (IPC)
- LMWH as per hospital protocol (e.g. enoxaparin 40 mg SC once daily, dalteparin 5000 U SC once daily), or rarely UFH 5000 IU SC BID, UFH 5000 IU SC TID
- DOACs for orthopedic surgery thromboprophylaxis

Table 29. Contraindications of Anticoagulant Therapy

Absolute Contraindications to Treatment	Relative Contraindications to Treatment
Active bleeding Severe bleeding diathesis or platelet count <20 x 10^9/L (<20000/mm^3)	Mild-moderate bleeding diathesis or thrombocytopenia Recent major trauma Recent stroke Major abdominal surgery within past 2 d GI/GU bleeding within 1-4 d Endocarditis Neurosurgery or ocular surgery within 10 d

Treatment of Pulmonary Embolism

- see Respirology, R20

Effect of Treatment Delay on the Effectiveness and Safety of Antifibrinolytics in Acute Severe Hemorrhage: a Meta-analysis of Individual Patient-level Data from 40138 Bleeding Patients
Lancet 2018;391:125-132
Purpose: To examine if the effectiveness of antifibrinolytics in reducing death from acute severe hemorrhage is influenced by treatment delay.
Methods: Meta-analysis of individual patient-level data from 2 RCTs with 40138 total patients that investigated the use of tranexamic acid in acute severe bleeding. Treatment benefit was measured by absence of death from bleeding and logistic regression was used to assess the effect of treatment delay.
Results: Overall survival from bleeding was significantly increased by tranexamic acid (OR 1.2; 95% CI 1.08-1.33; P=0.001). Survival was improved by >70% with immediate treatment (OR 1.72, 95% CI 1.42–2.10; P<0.0001). In contrast, treatment benefit was significantly reduced by treatment delay (P<0.0001). Specifically, survival was reduced by 10% for every 15 min delay of treatment until 3 h, at which point no benefit was demonstrated.
Conclusion: Patients with severe acute bleeding should be treated immediately, as even a short delay in treatment reduces the survival benefit of tranexamic acid.

ASCO Clinical Practice Guidelines for VTE Prophylaxis and Treatment in Patients with Cancer
J Clin Oncol 2020;38:496-520
Clinicians can offer thromboprophylaxis (apixaban, rivaroxaban, or LMWH) for:
- High-risk outpatients with cancer
- As options for VTE treatment
- For long-term anticoagulation (min. 6 mo; better efficacy profiles than vitamin K antagonists)
- Throughout hospitalization (patients with cancer and an acute medical condition)
- Major cancer surgery (prophylaxis starting prior and continuing for min. 7-10 d)

Initiation of Warfarin Therapy Requires Bridging with Heparin Therapy for 4-5 Days
10 mg loading dose of warfarin causes a precipitous decline in protein C levels in first 36 h resulting in a transient hypercoagulable state
Warfarin decreases Factor VII levels in first 48 h, INR is prolonged (most sensitive to Factor VII levels), however full antithrombotic effect is not achieved until Factor IX, X, and II are sufficiently reduced (occurs after ~4 d)

Low-Risk Surgical Patients
<40 yr, no risk factors for VTE, general anesthetic (GA) <30 min, minor elective, abdominal, or thoracic surgery

Moderate-Risk Surgical Patients
>40 yr, >1 risk factor for VTE, GA >30 min

High-Risk Surgical Patients
>40 yr, surgery for malignancy or lower extremity orthopedic surgery lasting >30 min, inhibitor deficiency, or other risk factors

High-Risk Medical Patients
Heart failure, severe respiratory disease, ischemic stroke or lower limb paralysis, confined to bed, and have >1 additional risk factor (e.g. active cancer, previous VTE, sepsis, acute neurologic disease, IBD)

Hematologic Malignancies and Related Disorders

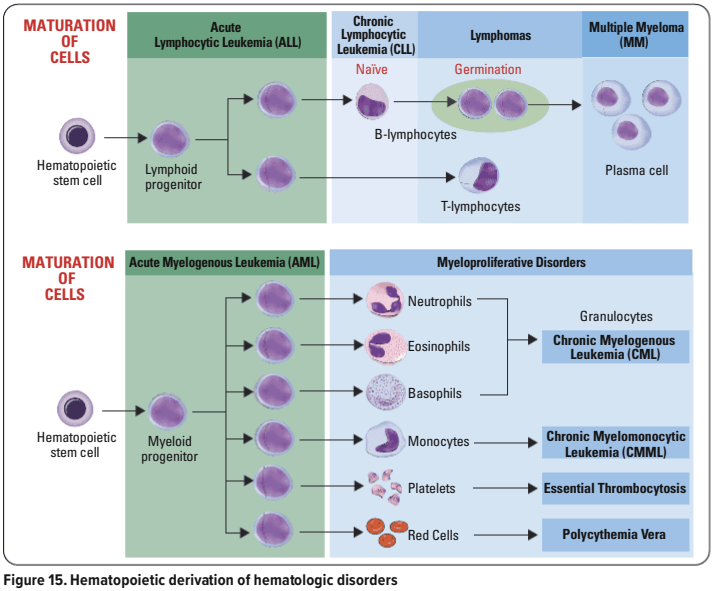

Figure 15. Hematopoietic derivation of hematologic disorders

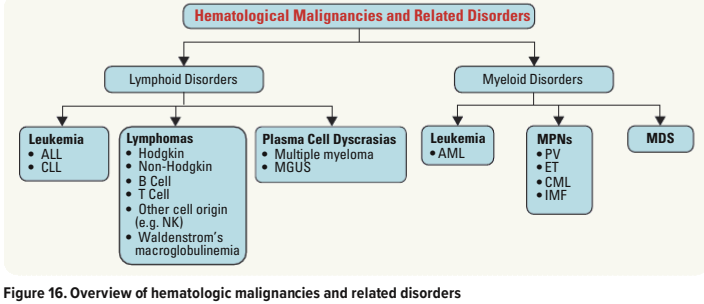

Figure 16. Overview of hematologic malignancies and related disorders

Leukemia: malignant cells arise in BM that may spread elsewhere (including blood, lymph nodes, and lymphoid tissue)
Lymphoma: malignant cells arise in lymph nodes and lymphoid tissues that may spread elsewhere (including blood and BM)
BUT the location where the malignant cells are found does not solely define the type of hematologic malignancy – classified based on the characteristics of the cell (histology, histochemistry, immunophenotyping, cytogenetics, molecular changes)

Acute Leukemia
Definition (WHO): presence of 20% blast cells or greater in the peripheral blood or BM at presentation
Classification: divided into myeloid (AML) and lymphoid (ALL) depending on whether blasts are myeloblasts or lymphoblasts, respectively

Typical Age of Presentation of Leukemias
ALL: Children and older adults
CML: 40-60 yr
AML, **CLL**: >60 yr

Auer rods are pathognomonic for AML

Basic Initial Workup for all Hematologic Malignancies:
1. ALL WOMEN OF CHILDBEARING AGE must have a b-HCG before initiation of treatment of any cancer diagnosis
2. ALL PATIENTS MUST HAVE Hepatitis B surface antibody (HBsAb), Hepatitis B surface antigen (HBsAg), Hepatitis B core antibody (HBcAb) collected irrespective of cancer diagnosis and must be treated to avoid reactivation
3. All aggressive lymphoma patients must be screened for HIV
4. All patients must be screened for TB risk factors

Cure: survival that parallels age-matched population
Complete Remission: tumour load below threshold of detectable disease (normal peripheral blood film, normal BM with <5% blasts, normal clinical state)

Myeloid Malignancies

Acute Myeloid Leukemia

Definition
- rapidly progressive malignancy characterized by failure of myeloid cells to differentiate beyond blast stage

Epidemiology
- incidence increases with age; median age of onset is 65 yr; accounts for 80% of acute adult leukemias
- accounts for 10-15% of childhood leukemias

Risk Factors
- male, older age, smoking, obesity, MDS, benzene, radiation, Down syndrome, alkylating agents, and radiation therapy as treatment for previous malignancy

Pathophysiology
- etiology subdivided into:
  - primary: *de novo*
  - secondary: prior hematologic malignancies (e.g. myeloproliferative disorders and MDS) or previous chemotherapeutic agents (e.g. alkylating agents)
- uncontrolled growth of blasts in marrow leads to:
  - suppression of normal hematopoietic cells
  - appearance of blasts in peripheral blood – risk of leukostasis
  - accumulation of blasts in other sites (e.g. skin, gums)
  - metabolic consequences; TLS
- cancer stem cells thought to play key role in development and progression, subpopulation of self-renewing cancer cells with unique surface markers such as CD34, CD38, CD123

Clinical Features
- signs and symptoms develop over a period of weeks
- manifestations of BM failure
  - anemia, thrombocytopenia (associated with DIC in APL), neutropenia (and infection/fever)
- accumulation of blast cells in marrow
  - skeletal pain, bony tenderness (especially sternum)
- organ infiltration
  - gingival hypertrophy (particularly myelomonocytic leukemia) – may present to dentist first
  - CNS extramedullary involvement: confusion or altered mental status
  - hepatosplenomegaly (also present in ALL)
  - lymphadenopathy
  - skin: leukemia cutis
  - eyes: hemorrhages and/or whitish plaques, Roth spots, cotton wool spots, and vision changes (uncommon)
- leukostasis/hyperleukocytosis syndrome (medical emergency)
  - large numbers of blasts interfere with circulation and lead to hypoxia and hemorrhage – can cause diffuse pulmonary infiltrates, CNS bleeding, respiratory distress, altered mental status, and priapism
  - more commonly associated with AML than ALL
- metabolic effects (aggravated by treatment)
  - TLS
    - increased uric acid → nephropathy, gout
    - release of phosphate → decreased Ca^{2+}, decreased Mg^{2+}
    - release of procoagulants → DIC (higher risk in APL)
  - hyperkalemia pre-treatment from blastic proliferation and spontaneous TLS, further hyperkalemia after treatment (from lysed cells). Note – some forms of AML can present with hypokalemia due to secreted muramidase that causes K+ wasting from renal tubules

Investigations
- blood work
  - CBC: anemia, thrombocytopenia, variable WBC (most often cytopenias + blasts)
  - INR up, aPTT up, FDP up, fibrinogen down (in case of DIC)
  - increased LDH, increased uric acid, increased PO_4^{3-} (released by leukemic blasts), decreased Ca^{2+}, increased/decreased K^+
  - baseline renal and liver function tests
  - if considering treatment: screen for HBV, HCV, HIV, CMV serology
- peripheral blood film – circulating blasts with Auer rods (azurophilic granules) are pathognomonic for AML
- BM aspirate for definitive diagnosis
  - blast count: AML >20% (normal is <5%)
  - morphologic, cytogenetic, and/or immunophenotypic features are used to establish lineage and maturation
- CXR to rule out pneumonia; ECG, MUGA scan prior to chemotherapy (cardiotoxic)

Treatment
- mainstay of treatment is chemotherapy (rapidly fatal without treatment)
- patients who are not eligible for intensive chemotherapy can be treated with low-dose cytarabine and hypomethylating agents in combination with venetoclax (BCL-2 inhibitor)
- all AML subtypes are treated similarly, except APL with t(15:17) translocation
  1. **induction**: chemotherapy to induce complete remission of AML
     - several possible regimens
     - patients with poor response to initial induction therapy – worse prognosis
     - supportive care - management of TLS and DIC, febrile neutropenia/infections, transfusion support (including platelet transfusions if $<10 \times 10^9$/L)
  2. **consolidation**: to prevent recurrence
     - intensive consolidation chemotherapy

- stem cell transplantation – allogeneic (younger patients with better performance status and/or adverse cytogenetics)

- supportive care
  - fever: pan-cultures, CXR, and start broad-spectrum antibiotics
  - platelet and RBC transfusions
  - prevention and treatment of metabolic abnormalities
    - allopurinol, rasburicase for prevention/management of hyperuricemia
  - leukostasis
    - needs immediate cytoreductive therapy (i.e. hydroxyurea)
  - treatment strategy for APL
    - APL is an emergency as DIC is often present at diagnosis
    - ATRA added to induce differentiation (should be started ASAP if APL is in the differential); arsenic trioxide and ATRA combination therapy for APL is superior to traditional chemotherapy

Prognosis

- achievement of first remission
  - 70-80% if ≤60 y/o, 50% if >60 y/o
  - median survival 12-24 mo
  - prognosis depends on cytogenetics, age, performance status, prior cytotoxic agents, or radiation therapy

Myelodysplastic Syndromes

Definition

- heterogeneous group of malignant stem cell disorders characterized by dysplastic and ineffective blood cell production resulting in peripheral cytopenias and a variable risk of transformation to acute leukemias
- syndromes defined according to WHO classifications

Pathophysiology

- disordered maturation: ineffective hematopoiesis despite presence of adequate numbers of progenitor cells in BM (usually hypercellular); formed elements sometimes exhibit morphological and functional defects
- intramedullary apoptosis: programmed cell death within BM
- both processes lead to reduced mature cells in periphery
- <30% develop AML

Risk Factors

- elderly, post-chemotherapy, exposures (benzene, tobacco, radiation), inherited genetic abnormalities
- incidence: 50 persons per million per year, rises to 200-400 per million per year for age 70 or older

Clinical Features

- highly variable, commonly presents with symptoms of anemia (fatigue and dyspnea), thrombocytopenia (bruising, bleeding, or petechiae), and neutropenia (recurrent infections) over months-years

Investigations

- diagnosed by:
  - anemia ± thrombocytopenia ± neutropenia
  - CBC and peripheral blood film
  - RBC: usually macrocytic with oval shaped red cells (macro-ovalocytes), decreased reticulocyte count
  - WBC: decreased granulocytes and abnormal morphology (e.g. bi-lobed or unsegmented nuclei = Pelger abnormality)
  - platelets: thrombocytopenia, abnormalities of size, and cytoplasm (e.g. giant hypogranular platelets)
- BM aspirate and biopsy with cytogenetic analysis required for definitive diagnosis
  - BM: dysplastic and often normocellular/hypercellular
  - cytogenetics: high-risk (partial or total loss of chromosome 7) and complex (>3 abnormalities)

Treatment

- low-risk of transformation to acute leukemia (Revised International Prognostic Scoring System (IPSS-R) Very Low or Low)
  - EPO stimulating agents weekly is first line in reducing transfusion requirements (EPO level must be <500 IU/L)
  - if 5q deletion based on cytogenetics: lenalidomide PO
  - supportive care: RBC and platelet transfusion (consider iron chelation if frequent RBC transfusions)
- high-risk of transformation to acute leukemia (IPSS-R Intermediate, High, or Very High)
  - supportive care (transfusion support)
  - epigenetic therapy: DNA methyltransferase inhibitors (e.g. 5-azacitidine)
  - consider stem cell transplantation according to patient factors (age, frailty, overall health)

Prognosis
- IPSS-R uses 5 factors to estimate mean survival:
  - cytology, % BM blasts, Hb, platelets, and ANC
  - based on the calculated score, a patient's MDS prognostic risk is "Very Low", "Low", "Intermediate", "High", or "Very High" with a mean survival of 8.7, 5.3, 3.0, 1.6, and 0.8 yr, respectively

Myeloproliferative Neoplasms

Definition
- clonal myeloid stem cell abnormalities leading to overproduction of one or more cell lines (erythrocytes, platelets, and other cells of myeloid lineage)

Epidemiology
- mainly middle-aged and older patients (peak 60-80 yr)

Prognosis
- may develop marrow fibrosis with time
- all disorders may progress to AML

Table 30. Chronic Myeloproliferative Disorders

	CML	PV	IMF	ET
Hct	↓/N	↑↑	↓	N
WBC	↑↑	↑	↑/↓	N
Plt	↑/↓	↑	↑/↓	↑↑↑
Marrow Fibrosis	±	±	+++	±
Splenomegaly	+++	+	+++	+
Hepatomegaly	+	+	++	–
Genetic Association	BCR-ABL mut.	JAK2 mut. (96%)	JAK2 mut. (~50%) CALR mut. (~30%)	JAK2 mut. (~50%) CALR mut. (~30%)

Chronic Myeloid Leukemia

Definition
- myeloproliferative disorder characterized by increased proliferation of the granulocytic cell line without the loss of their capacity to differentiate

Epidemiology
- occurs in any age group (mostly middle age to elderly) with a median age of 65 yr

Pathophysiology
- Ph chromosome
  - translocation between chromosomes 9 and 22 is necessary and sufficient to result in CML
  - the c-Abl proto-oncogene is translocated from chromosome 9 to "breakpoint cluster region" (BCR) of chromosome 22 to produce BCR-ABL fusion gene, a constitutively active tyrosine kinase

Clinical Features
- 3 clinical phases
  - chronic phase: 85% diagnosed here
    - few blasts (<10%) in peripheral film
    - ± slightly elevated eosinophils and basophils
    - no significant symptoms
  - accelerated phase: impaired neutrophil differentiation
    - circulating blasts (10-20%) with increasing peripheral basophils (pruritus)
    - CBC: thrombocytopenia <100 x 10^9/L or thrombocytosis
    - cytogenetic evidence of clonal evolution
    - worsening constitutional symptoms and splenomegaly (extramedullary hematopoiesis)
  - blast crisis: more aggressive course, blasts fail to differentiate
    - blasts (>20%) in peripheral blood or BM; reflective of acute leukemia (1/3 ALL, 2/3 AML)
- clinical features
  - 20-50% of patients are asymptomatic when diagnosed (incidental lab finding)
  - nonspecific symptoms
    - fatigue, weight loss, malaise, excessive sweating, fever

Use of Epoetin and Darbepoetin in Patients with Cancer
Blood 2008;111:25-41
Clinical practice guideline update by American Societies of Hematology and Clinical Oncology (2010).
Initial Recommendations
1. Initiate an ESA when Hb is 100 g/L (10 g/dL) in patients with palliative chemotherapy-associated anemia to decrease the need for transfusions
2. Discontinue ESAs when patient not responding to treatment beyond 6-8 wk
3. Monitor iron stores and supplement iron intake for ESA-treated patients when necessary
4. Use ESAs cautiously with chemotherapy or in patients with an elevated risk for thromboembolic complications
5. It is not recommended that ESA be used for therapy in patients with cancer who are not receiving chemotherapy as it increases thromboembolic risks and lowers survival rate. Patients with low-risk myelodysplasia are an exception

MDS ineffective maturation
MPN overproduction of mature cells

Basophilia is uncommon in other medical conditions

Chronic Myeloproliferative Neoplasms: 11-Year Follow-Up of Patients Receiving Imatinib for the First-Line Treatment of CML
NEJM 2017;376:917-927
Study: Long-term outcomes of imatinib treatment for chronic myeloid leukemia.
Methods: 1106 patients with Ph-positive CML in the chronic phase were randomized 1:1 to imatinib or interferon alpha plus cytarabine. Crossover to imatinib was allowed if no response by 6 mo or major cytogenetic response by 12 mo.
Results: Assessing the imatinib arm after a median of 11 years of follow-up, the complete cytogenetic response rate was 83%. Among patients who attained a major molecular response after 18 mo of imatinib therapy, the overall survival at 10 years was 93% and freedom from CML-related deaths was 100%.
Conclusion: This 11-year update of IRIS demonstrates the efficacy and safety of imatinib as first-line therapy for CML patients.

- secondary to splenic involvement
  - early satiety, LUQ pain/fullness, shoulder tip pain (referred)
  - splenomegaly (most common physical finding)
- anemia
- bleeding: secondary to platelet dysfunction
- pruritus, PUD: secondary to increased blood histamine
- leukostasis, priapism, encephalopathy: secondary to very elevated WBC (rare)

Investigations

- CBC with differential
  - elevated WBCs, decreased/normal RBCs, increased/decreased platelets, increased basophils
  - WBC differential shows a bimodal distribution, with predominance of myelocytes and neutrophils
- peripheral blood film
  - leukoerythroblastic picture (immature red cells and granulocytes present, e.g. myelocytes and normoblasts)
  - presence of different mid-stage progenitor cells differentiates it from AML
- BM biopsy
  - myeloid hyperplasia with left shift, increased megakaryocytes, mild fibrosis
- molecular and cytogenetic studies of BM or peripheral blood for Ph chromosome (or BCR-ABL transcripts)
- abdominal imaging for spleen size

Treatment

- **prophylactic**: allopurinol
- **chronic phase**
  - imatinib mesylate inhibits proliferation and induces apoptosis by inhibiting tyrosine kinase activity in cells positive for BCR-ABL. 2nd/3rd generation can be used as first line therapy
    - if loss of response or intolerance (~40%), trial of 2nd or 3rd generation TKIs: dasatinib, nilotinib, or bosutinib. Note: ponatinib only provided for the T315I mutation
  - interferon-α: may improve response to TKIs; typically now only used for pregnant patients
  - hydroxyurea in palliative setting to reduce WBCs
- **accelerated phase or blast phase**
  - for imatinib-naive patients, use imatinib
  - refer for clinical trial or 2nd/3rd generation TKI and prepare for allogeneic stem cell transplant patients, in blast phase typically get standard induction for acute leukemia
- stem cell transplantation may be curative: to be considered in young patients who do not meet therapeutic milestones
- treatment success is monitored based on therapeutic milestones
  - hematologic: improved WBC and platelet counts, reduced basophils
  - cytogenetic: undetectable Ph chromosome in the BM
  - molecular: reduction/absence of BCR-ABL transcripts in periphery and marrow

Prognosis

- survival dependent on response
  - those achieving complete cytogenetic response (CCR) on imatinib by 18 mo of therapy: 6 yr overall survival >90%
  - those who do NOT achieve CCR on imatinib: 6 yr overall survival of 66%
- acute phase (blast crisis – usually within 3-5 yr of presentation if untreated CML)
  - 2/3 acute phase CML have cellular features similar to AML
    - unresponsive to remission induction
  - 1/3 acute phase CML have cellular features similar to ALL
    - remission induction (return to chronic phase) achievable

Polycythemia Vera

Definition

- stem cell disorder characterized by elevated RBC count (erythrocytosis) ± increased white cell and platelet production
- diagnosis (WHO 2016) requires meeting either all 3 major criteria, or the first 2 major criteria and the minor criterion
  - Major Criteria
    1. Hb >165 g/L in men, >160 g/L in women, OR Hct >49% in men, >48% in women, OR increased red cell mass (>25% above mean normal predicted value)
    2. BM biopsy showing hypercellularity for age with trilineage growth (panmyelosis) with prominent erythroid, granulocytic, and megakaryocytic proliferation
    3. presence of JAK2 V617F or JAK2 exon 12 mutation
  - Minor Criterion
    1. serum EPO level below reference range for normal (must have the first two major criteria if using EPO level)

Erythromelalgia is a pathognomonic microvascular thrombotic complication in PV and ET

Cardiovascular Events and Intensity of Treatment in Polycythemia Vera
NEJM 2013;368:22-33
Study: Prospective, RCT, mean follow-up of 28.9 mo. Blinding not described.
Population: 365 patients with JAK2-positive polycythemia vera being treated with phlebotomy, hydroxyurea, or both.
Intervention: Patients were randomized to a target hematocrit <45% (low-hematocrit group) or 45-50% (high-hematocrit group).
Outcome: Composite of time until death from cardiovascular causes of major thrombotic events.
Results: The hazard ratio (HR) for the primary outcome was 3.91 (95% CI 1.45-10.53, P=0.007), while the HR for the primary outcome plus superficial venous thrombosis was 2.69 (95% CI 1.19-6.12, P=0.02) for the high-hematocrit vs. low-hematocrit group.
Conclusions: The hematocrit target of <45% was associated with a lower incidence of CV death, major thrombotic events, and superficial venous thrombosis in patients with polycythemia vera.

Clinical Features
- symptoms are secondary to high red cell mass and hyperviscosity (see *Erythrocytosis, H7*)
- thrombotic complications: DVT, PE, Budd-Chiari (hepatic vein thrombosis), portal vein thrombosis, thrombophlebitis, increased incidence of stroke/TIA, and MI
  - due to increased blood viscosity, increased platelet number, and/or activity
  - bleeding complications: epistaxis, gingival bleeding, ecchymoses, and GI bleeding
  - if high platelet counts: associated with acquired VWD (although seen more with ET)
- erythromelalgia (burning pain in hands and feet and erythema of the skin)
  - associated with platelets >400 x 10^9/L
  - pathognomonic microvascular thrombotic complication in PV and ET
- pruritus, especially after warm bath or shower (40%) due to cutaneous mast cell degranulation and histamine release
- epigastric distress, PUD
  - due to increased histamine from tissue basophils, alterations in gastric mucosal blood flow due to increased blood viscosity
- gout (hyperuricemia), due to increased cell turnover
- characteristic physical findings
  - plethora (ruddy complexion) of face (70%), palms
  - splenomegaly (70%), hepatomegaly (40%)

Investigations *(see Erythrocytosis, H7)*
- must rule out secondary polycythemia if high EPO level

Treatment
- phlebotomy to keep hematocrit <45%
- hydroxyurea (prior thrombosis or symptoms, severe coronary artery disease, refractory to phlebotomy)
- ruxolitinib for those with insufficient response or intolerance to hydroxyurea
- low-dose ASA (for antithrombotic prophylaxis, will also treat erythromelalgia)
- allopurinol: as needed
- antihistamines: as needed

Prognosis
- 10-20 yr survival with treatment
- complicated by thrombosis, hemorrhage, leukemic transformation (AML)

Idiopathic Myelofibrosis

Definition
- excessive BM fibrosis leading to marrow failure
- characterized by anemia, extramedullary hematopoiesis, leukoerythroblastosis, teardrop red cells in peripheral blood, and hepatosplenomegaly

Epidemiology
- rare, median age at presentation is 65 yr

Pathophysiology
- abnormal myeloid precursor postulated to produce dysplastic megakaryocytes that secrete fibroblast growth factors
  - stimulates fibroblasts and stroma to deposit collagen in marrow
- increasing fibrosis causes early release of hematopoietic precursors leading to:
  - leukoerythroblastic blood film (see below)
  - migration of precursors to other sites: extramedullary hematopoiesis (leading to hepatosplenomegaly)

Clinical Features
- anemia (severe fatigue is most common presenting complaint, pallor on exam in >60%)
- weight loss, fever, night sweats → secondary to hypermetabolic state
- splenomegaly (90%) → secondary to extramedullary hematopoiesis; may cause early satiety and severe left upper quadrant pain
- hepatomegaly (70%) → may develop portal hypertension
- bone and joint pain → secondary to osteosclerosis, gout
- signs of extramedullary hematopoiesis (depends on organ involved)

Investigations
- CBC: anemia, variable platelets, variable WBC
- biochemistry: increased ALP (liver involvement, bone disease), increased LDH (2° to ineffective hematopoiesis), increased uric acid (increased cell turnover), increased B_{12} (2° to increased neutrophil mass)
- blood film: leukoerythroblastosis with teardrop RBCs, nucleated RBCs, variable polychromasia, large platelets, and megakaryocyte fragments
- molecular test: JAK2 (70%) and CALR(25%) mutations
- BM aspirate: "dry tap" in as many as 50% of patients (no marrow spicules aspirated)
- BM biopsy (essential for diagnosis): fibrosis, atypical megakaryocytic hyperplasia, thickening and distortion of the bony trabeculae (osteosclerosis)

Efficacy and Safety of Low-dose Aspirin® in Polycythemia Vera
NEJM 2004;350:114-124
Study: Double-blind, placebo-controlled, RCT.
Participants: 518 patients with polycythemia vera (PV) with no clear indication for, or contraindication to, ASA therapy.
Intervention: Patients received either low-dose ASA 100 mg daily (n=253) or placebo (n=265) and were followed for up to 5 yr.
Primary Outcome: Cumulative rate of (I) nonfatal MI, nonfatal stroke, or death from cardiovascular causes and the cumulative rate of (II) the previous 3 plus PE and major venous thrombosis.
Results: Primary outcomes (I) and (II) were reduced with treatment compared to placebo (RR 0.41; P=0.09 and RR 0.4; P=0.03, respectively). There were no differences in overall or cardiovascular mortality and major bleeding episodes.
Conclusion: Low-dose ASA can safely prevent thrombotic complications in patients with PV.

Ruxolitinib Versus Standard Therapy for the Treatment of Polycythemia Vera
NEJM 2015;372:426-35
Purpose: To evaluate the efficacy and safety of ruxolitinib vs. standard therapy in patients with PV who had insufficient responses or intolerable side effects with hydroxyurea.
Methods: 222 phlebotomy-dependent patients with splenomegaly were randomly assigned to receive ruxolitinib or standard therapy.
Primary Outcome: Hematocrit control through week 32 and spleen volume reduced ≥35% at week 32.
Results: 21% of patients on ruxolitinib vs. 1% of those on standard-therapy achieved the primary outcome (P<0.001). 60% of patients on ruxolitinib and 20% on standard therapy achieved hematocrit control. ≥35% reduction in spleen volume was seen in 38% and 1% of patients in the two groups, respectively. Compared to standard-therapy, ruxolitinib was associated with a significantly greater rate of complete hematologic remission (24% vs. 9%; P=0.003).
Conclusion: Ruxolitinib was superior to standard therapy in controlling hematocrit, reducing the spleen volume, and improving symptoms associated with PV in patients who had insufficient responses or intolerable side effects with hydroxyurea.

Myelofibrosis can be either primary (idiopathic) or occur as a transformation of an antecedent PV or ET

A "leukoerythroblastic" blood film (RBC and granulocyte precursors) implies BM infiltration with malignancy (e.g. leukemias, solid tumour metastases) or fibrosis (e.g. IMF)

IMF typically has a dry BM aspirate and teardrop RBCs (aspiration gives no blood cells)

Treatment
- allogeneic stem cell transplant is potentially curative
- JAK2 inhibitors (ruxolitinib, fedratinib, or hydroxyurea)
- symptomatic treatment
  - transfusion for anemia
  - EPO: 30-50% of patients respond
  - androgens for anemia (e.g. danazol has shown transient response with response rates of <30%)
  - hydroxyurea for splenomegaly, thrombocytosis, leukocytosis, and systemic symptoms
    - interferon-α (as second line therapy)
    - splenectomy (as third line therapy; associated with high mortality and morbidity)
  - radiation therapy for symptomatic extramedullary hematopoiesis and symptomatic splenomegaly

Prognosis
- Dynamic International Prognostic Scoring System (DIPSS) Plus for IMF uses 5 risk factors along with karyotype, platelet count, and transfusion status to predict survival
  - presence of constitutional symptoms; age >65; Hb <100 g/L; leukocyte count >25000/mm ^{3}; circulating blast cells ≥1%
  - based on the calculated score, a patient's IMF is categorized as "low", "intermediate 1", "intermediate 2", or "high" with a mean survival of 185, 78, 35, and 16 mo, respectively
  - eligible patients with intermediate 2 or high risk DIPSS are considered for allogeneic stem cell transplant
- risk of transformation to AML (8-10%)

A Double-Blind, Placebo-Controlled Trial of Ruxolitinib for Myelofibrosis
NEJM 2012;366:799-807
Study: Double-blinded RCT of 309 patients with myelofibrosis randomized to ruxolitinib or placebo.
Outcome: Primary outcome was reduction in spleen volume of >35% at 24 wk. Secondary outcomes were durability of response, symptom burden, and overall survival.
Results: A greater proportion of patients on ruxolitinib had reduction in spleen volume >35% (41.9% vs. 0.7%) and this was sustained in 67% at 48 wk. Ruxolitinib also led to greater symptom improvement (45% vs. 5.3%) and less mortality (13 vs. 24). There was no difference in rate of discontinuation due to adverse events (11.0% vs. 10.6%) but anemia and thrombocytopenia were more common with ruxolitinib.
Conclusions: Ruxolitinib reduced spleen size, and improved symptoms and survival, compared with placebo.

Essential Thrombocythemia

Definition
- overproduction of platelets in the absence of recognizable stimulus
- must rule out secondary thrombocythemia

Epidemiology
- increases with age; F:M=2:1, → F=M at older

Diagnosis (2008 WHO Criteria Revised in 2016) requires meeting all four criteria
1. sustained platelet count >450 x 10^9/L
2. BM biopsy specimen showing proliferation mainly of the megakaryocytic lineage with increased number of enlarged, mature megakaryocytes; no significant increase or left shift of neutrophil granulopoiesis or erythropoiesis
3. not meeting WHO criteria for PV, primary myelofibrosis, BCR-ABL CML, or MDS or other myeloid neoplasms
4. most patients have a mutation in JAK2 V617F, CALR, or MPL. A minority (~10%) have a mutation in some other gene, which causes proliferation (hence "clonal marker")

Etiology of Secondary Thrombocythemia
Infection
Inflammation (IBD, arthritis)
Malignancy
Hemorrhage
Iron deficiency
Hemolytic anemia
Post-splenectomy
Post-chemotherapy
Drugs (vinca alkaloids)

Clinical Features
- often asymptomatic
- vasomotor symptoms (40%)
  - headache (common), dizziness, syncope
  - erythromelalgia (burning pain of hands and feet, dusky colour, usually worse with heat, caused by platelet activation → microvascular thrombosis)
- thrombosis (arterial and venous)
- bleeding (often GI; associated with platelets >1000 x 10^9/L)
- constitutional symptoms, splenomegaly
- pregnancy complications; increased risk of spontaneous abortion
- risk of transformation to AML (0.6-5%), myelofibrosis

Investigations
- CBC: increased platelets; may have abnormal platelet aggregation studies or VWD studies
- JAK2 (and other) mutational assays
- BM hypercellularity, megakaryocytic hyperplasia, giant megakaryocytes
- increased K^+, increased PO_4^{3-} (2º to release of platelet cytoplasmic contents)
- diagnosis: exclude other myeloproliferative disorders and reactive thrombocytosis

Treatment
- low dose ASA
- cytoreductive therapy if thrombosis or thrombotic symptoms: hydroxyurea (HU) (1st-line therapy), anagrelide, interferon-α, or 32P (age >80 or lifespan <10 yr)

There is an asymptomatic "benign" form of essential thrombocythemia with a stable or slowly rising platelet count; treatment includes observation, ASA, sulfinpyrazone, or dipyridamole

Lymphoid Malignancies

Acute Lymphoblastic Leukemia

75% of ALL occurs in children <6 yr; second peak at age 40

Definition
- malignant disease of the BM in which early lymphoid precursors proliferate and replace normal hematopoietic cells
- WHO subdivides ALL into two types depending on cell of origin
  - 1. B-cell: precursor B lymphoblastic leukemia
  - 2. T-cell: precursor T lymphoblastic leukemia
- the French-American-British (FAB) classification (L1, L2, L3) is no longer encouraged as morphology is not prognostic

Clinical Features
- see *Acute Myeloid Leukemia, H39* for full list of symptoms
- distinguish ALL from AML based on *Table 32*
- clinical symptoms usually secondary to:
  - BM failure: anemia, neutropenia (50% present with fever; also infections of oropharynx, lungs, perianal region), and thrombocytopenia
  - organ infiltration: tender bones, lymphadenopathy, hepatosplenomegaly, meningeal signs (headache, N/V, visual symptoms; especially in ALL relapse)

Investigations
- >20% BM or peripheral blood lymphoblasts, with samples collected for flow cytometry, cytogenetics, and molecular studies
- Ph chromosome in ~25% of adult ALL cases
- CBC: increased leukocytes >100 x 10^9/L (occurs in 50% of patients); neutropenia, anemia, or thrombocytopenia
- screen for TLS: increased uric acid, K^+, PO_4^{3-}, low Ca^{2+}, high LDH
- screen for DIC: PT, aPTT, fibrinogen
- CXR: patients with ALL may have a mediastinal mass
- CT C/A/P and testicular ultrasound to screen for extranodal disease
- mandatory lumbar puncture to assess for CNS involvement (ensure adequate platelet count and PT/PTT and delay until blasts have cleared from peripheral blood) at the time treatment is initiated
- HIV, HBV, HCV serologies, CMV Ab testing

Treatment
- eliminate abnormal clonal cells
  1. induction chemotherapy: to induce complete remission, <5% blasts (restore normal hematopoiesis)
  2. consolidation and/or intensification of chemotherapy
     - consolidation: continuing same chemotherapy to eliminate subclinical leukemic cells
     - intensification: high doses of different (non-cross-reactive) chemotherapy drugs to eliminate cells with resistance to primary treatment
  3. maintenance chemotherapy: low dose intermittent chemotherapy over prolonged period (1 yr) to prevent relapse
  4. prophylaxis: CNS radiation therapy or methotrexate (intrathecal or systemic)
- hematopoietic stem cell transplantation (for certain indications): potentially curative (due to pre-transplant myeloablative chemoradiation and post-transplant graft-versus-leukemia effect) but relapse rates and non-relapse mortality high
  - if BCR-ABL positive, tyrosine kinase inhibitors started up front and given continuously
  - in relapse setting, CAR T-cell therapy, inotuzumab, or blinatumomab
- CAR T-cell therapy
  - extraction of patient's own T-cells, genetic modification of T-cells to produce Chimeric Antigen Receptors (CARs) that recognize antigens presented selectively on cancer cell surface (often CD19 in ALL)
  - most effective in treating diffuse large B-cell lymphoma and CD19-positive ALL
  - first approved in Canada in 2018, currently of limited utility in treating other types of hematologic malignancies and solid tumours

Treatment of ALL vs. AML
No proven benefit of maintenance chemotherapy in AML
No routine CNS prophylaxis in AML

Prognosis
- depends on response to initial induction, minimal residual disease testing, or if remission is achieved following relapse
- good prognostic factors: young, WBC <30 x 10^9/L, T-cell phenotype, absence of Ph chromosome, early attainment of complete remission
- achievement of first remission: 60-90%
- childhood ALL: 75% long-term remission (>5 yr)
  - higher cure rates in children because of better chemotherapy tolerance, lower prevalence of BCR-ABL fusion gene (associated with chemotherapeutic resistance)
- adult ALL: 30-40% 5 yr survival

Table 31. Differentiating AML From ALL

AML	ALL
Big people (adults)	Small people (kids)
Big blasts	Small blasts
Big mortality rate	Small mortality rate (kids)
Lots of cytoplasm	Less cytoplasm
Lots of nucleoli (3-5)	Few nucleoli (1-3)
Lots of granules and Auer rods	No granules and no Auer rods
Myeloperoxidase, Sudan black stain	PAS (periodic acid-Schiff)
Maturation defect beyond myeloblast or promyelocyte	Maturation defect beyond lymphoblast

To Differentiate AML from ALL: Remember Big and SmALL

Lymphomas

Definition

- collection of lymphoid malignancies in which malignant lymphocytes accumulate in lymph nodes and lymphoid tissues
  - leading to lymphadenopathy, extranodal disease, and constitutional symptoms

Table 32. Ann Arbor System for Staging Lymphomas

Stage	Description
I	Involvement of a single lymph node region or extralymphatic organ/site (Stage IE)
II	Involvement of ≥2 lymph node regions or an extralymphatic site and ≥1 lymph node regions on same side of diaphragm
III	Involvement of lymph node regions on both sides of the diaphragm
IV	Diffuse involvement of one or more extralymphatic organs including BM

American Society of Hematology Choosing Wisely Recommendation
Limit surveillance CT scans in asymptomatic patients after curative-intent treatment for aggressive lymphoma

- subtypes
  A = absence of B-symptoms (*see Approach to Lymphadenopathy, H12*)
  B = presence of B-symptoms

Table 33. Chromosome Translocations

Translocation	Gene Activation	Associated Neoplasm
t(2;5)	ALK1 mutation	Anaplastic large cell lymphoma
t(8;14)	c-Myc activation	Burkitt's lymphoma
t(14;18)	Bcl-2 activation	Follicular lymphoma
t(11;14)	Overexpression of cyclin D1 protein	Mantle cell lymphoma
t(11;18)	MALT1 activation	Mucosa-associated lymphoid tissue (MALT)

- Ann Arbor staging can be used for both Hodgkin and non-Hodgkin lymphoma, but grade/histology is more important for non-Hodgkin lymphoma because the outcome differs significantly depending on type of lymphoma
- Prognostic scores are different for indolent vs. aggressive lymphomas
- Highly aggressive lymphomas act like acute leukemias

Hodgkin Lymphoma

Definition

- malignant proliferation of lymphoid cells with Reed-Sternberg cells

Epidemiology

- bimodal distribution with peaks at 20 yr and >50 yr
- association with Epstein-Barr virus in up to 50% of cases and causal role not determined

Hodgkin is distinguished from non-Hodgkin lymphoma by the presence of Reed-Sternberg cells

Clinical Features

- asymptomatic lymphadenopathy (70%)
  - non-tender, rubbery consistency
  - cervical/supraclavicular (60-80%), axillary (10-20%), inguinal (6-12%)
- splenomegaly (50%) ± hepatomegaly
- mediastinal mass
  - found on routine CXR, may be symptomatic (cough)
  - rarely may present with superior vena cava syndrome and pleural effusion
- systemic symptoms
  - B-symptoms (≥1 of: unintentional weight loss ≥10% of body weight within previous 6 mo, temperature >38°C, or night sweats for ≥2 wk without evidence of infection), extreme fatigue especially in widespread disease, and pruritus
- non-specific/paraneoplastic
- starts at a single site in lymphatic system (node) and spreads first to adjacent nodes
  - disease progresses in contiguity with lymphatic system

Hodgkin lymphoma classically presents as a painless, non-tender, firm, rubbery enlargement of superficial lymph nodes, most often in the cervical region

Investigations

- CBC
  - anemia (chronic disease, rarely hemolytic), eosinophilia, lymphopenia, platelets normal or increased in early disease, and decreased in advanced disease

- biochemistry
  - HIV, HBV, HCV serologies
  - liver enzymes and/or LFTs (liver involvement)
  - renal function tests (prior to initiating chemotherapy)
  - ALP, Ca^{2+}(bone involvement)
  - ESR (prognosis), LDH (staging, monitor disease progression)
- imaging
  - CT chest (lymph nodes, mediastinal mass), CT abdomen/pelvis (liver or spleen involvement), and PET scan
  - cardiac function assessment (MUGA scan or echocardiography): for patients at high-risk of pre-treatment cardiac disease (age >60, history of HTN, CHF, PUD, CAD, MI, CVA), treatment can be cardiotoxic
  - PFTs: if history of lung disease (COPD, smoking, and previous radiation to lung)
- excisional lymph node or core biopsy confirms diagnosis
- BM biopsy to assess marrow infiltration (only necessary if B-symptoms, PET positive marrow on imaging, or cytopenia)

Treatment

Treatment of HL depends on stage; treatment of NHL depends on histologic subtype

- stage I-II: chemotherapy (ABVD (adriamycin, bleomycin, vinblastine, dacarbazine)) followed by involved field or involved site radiotherapy (XRT)
- stage III-IV: chemotherapy (ABVD, Brentuximab-AVD, or BEACOPP (bleomycin, etoposide, adriamycin, cyclophosphamide, vincristine, procarbazine, and prednisone)) ± XRT for bulky disease
- relapse, resistant to therapy: high dose chemotherapy and autologous stem cell transplant, anti-CD30 Ab therapy
  - PET scan results essential in assessing disease response

Complications of Treatment

- cardiac disease: secondary to XRT, adriamycin cardiomyopathy (1% of patients)
- pulmonary disease: secondary to bleomycin (interstitial pneumonitis)
- infertility: <3% with ABVD (important to discuss sperm banking/egg retrieval prior to initiation of chemotherapy)
- secondary malignancy in irradiated field
  - <2% risk of MDS, AML (secondary to treatment, usually within 8 yr)
  - solid tumours of lung or breast (>8 yr after treatment)
  - non-Hodgkin lymphoma
- hypothyroidism: post XRT

Prognosis

International Prognostic Factors Project 1998

Prognostic Factors	FFP
0	84%
1	77%
2	67%
3	60%
4	51%
5-7	42%

FFP = freedom from progression at 5 yr

- Hasenclever adverse prognostic factors:
  1. serum albumin <40 g/L
  2. Hb <105 g/L
  3. male
  4. stage IV disease
  5. age ≥45 yr
  6. leukocytosis (WBC >15 x 10^9/L)
  7. lymphocytopenia (lymphocytes <0.06 x 10^9/L or <8% of WBC count or both)
- each additional adverse prognostic factor decreases freedom from progression at 5 yr (FFP)

Non-Hodgkin Lymphoma

Definition

- malignant proliferation of lymphoid cells of progenitor or mature B- or T-cells

Classification

- can originate from both B- (85%) and T- or NK- (15%) cells
  - B-cell NHL: e.g. diffuse large B-cell lymphoma, follicular lymphoma, Burkitt's lymphoma, and mantle cell lymphoma
  - WHO/REAL classification system: 3 categories of NHLs based on natural history
    1. indolent (35-40% of NHL): e.g. follicular lymphoma, small lymphocytic lymphoma/CLL, and mantle cell lymphoma
    2. aggressive (~50% of NHL): e.g. diffuse large B-cell lymphoma
    3. highly aggressive (~5% of NHL): e.g. Burkitt's lymphoma
  - T-cell NHL: e.g. mycosis fungoides (indolent TCL of the skin), peripheral T-cell lymphoma-not otherwise specified (PTCL-NOS), and anaplastic large cell lymphoma

Clinical Features

- painless superficial lymphadenopathy, usually >1 lymph node region, rapid growth in aggressive lymphomas
- can have localized or widespread adenopathy (more common in indolent NHL)
- constitutional symptoms are less common in Hodgkin lymphoma
- cytopenia: anemia ± neutropenia ± thrombocytopenia can occur when BM is involved
- abdominal signs ± hepatosplenomegaly, retroperitoneal, and mesenteric involvement

- oropharyngeal involvement in 5-10% with sore throat and obstructive apnea
- extranodal involvement: most commonly GI tract, testes, bone, and kidney
- CNS involvement in 1% (often with HIV, testicular DLBCL, or >2 extranodal sites)

Investigations
- CBC
  - normocytic normochromic anemia
  - autoimmune hemolytic anemia rare (more common in CLL)
  - advanced disease: thrombocytopenia, neutropenia, and leukoerythroblastic blood film
- peripheral blood film may show lymphoma cells
- flow cytometry of peripheral blood only if lymphocytosis is present
- biochemistries, HIV, HBV, HCV serologies
  - increase in uric acid
  - abnormal LFTs in liver metastases
  - increased LDH (rapidly progressing disease and poor prognostic factor)
- SPEP and immunoglobulin quantitation (screen for high IgM monoclonal protein and hyperviscosity in indolent lymphomas, specifically lymphoplasmacytic lymphoma)
- staging: CT neck, chest, abdomen, pelvis, and BM biopsy
- PET imaging pre- and post-therapy to ensure post treatment remission
- diagnosed by:
  - lymph node biopsy: excisional biopsy is preferred, core biopsy (FNA is unreliable)
  - BM biopsy: sub-optimal mode of diagnosis as BM is involved in only 30% of high-grade lymphomas

Treatment
- indolent NHL, localized disease (e.g. stage I or II)
  - radiotherapy to primary site and adjacent nodal areas
  - splenectomy: splenic marginal zone lymphoma
- goal of treatment in stage III or IV indolent NHL is symptom management
  - watchful waiting
  - radiation therapy for localized symptomatic disease
  - bendamustine plus rituximab, an anti-CD20 Ab, is superior to CHOP and rituximab (CHOP-R) for advanced stage disease
  - obinutuzumab (novel anti-CD20 Ab) is superior to rituximab for advanced stage follicular lymphoma (GALLIUM Trial)
- aggressive lymphoma: goal of treatment is curative
  - combination chemotherapy: CHOP is mainstay, plus rituximab if B-cell lymphoma
  - radiation for localized/bulky disease
  - CNS prophylaxis with high-dose methotrexate if certain sites involved (e.g. testes)
  - relapse, resistant to therapy: high dose chemotherapy, autologous SCT, CAR T-cell therapy in second relapse
- highly aggressive lymphoma
  - Burkitt lymphoma: short bursts of intensive chemotherapy; "CODOX-M" chemotherapy regimen also often used ± IVAC with rituximab
  - CNS prophylaxis and (TLS) prophylaxis

NHL: Associated Conditions
Immunodeficiency (e.g. HIV)
Autoimmune diseases (e.g. SLE)
Infections (e.g. EBV)

Common Chemotherapeutic Regimens
R-CHOP: cyclophosphamide, hydroxydoxorubicin (Adriamycin®), vincristine (Oncovin®), prednisone
ABVD: adriamycin, bleomycin, vinblastine, dacarbazine
BEACOPP: bleomycin, etoposide, adriamycin, cyclophosphamide, vincristine, procarbazine, and prednisone

Complications
- hypersplenism
- infection
- autoimmune hemolytic anemia and thrombocytopenia
- vascular obstruction (from enlarged nodes)
- bowel perforation
- (TLS particularly in very aggressive lymphoma); see *Tumour Lysis Syndrome, H54*

Prognosis
- follicular lymphoma: Follicular Lymphoma International Prognostic Index is used: age >60; >4 nodal areas; >6 cm nodal areas; elevated LDH; Lugano stage III-IV; Hb <120 g/L; high β-2 microglobulin; BM involvement
  - based on calculated risk, mean 5 yr survival ranges from 53-91%
  - rarely curative, typically relapsing and remitting course with risk of transformation to aggressive lymphoma such as diffuse large B-cell lymphoma
- diffuse large B-cell lymphoma: The International Prognostic Factor Index is used (5 adverse prognostic factors): age >60; Ann Arbor stage (III-IV); performance status (ECOG/Zubrod 2-4); elevated LDH; >1 extranodal site
  - based on calculated risk, mean 5 yr survival ranges from 26-73%
  - ~40% rate of cure

Table 34. Characteristics of Select Non-Hodgkin Lymphomas

	Follicular Lymphoma	DLBCL	Burkitt Lymphoma	Mantle Cell Lymphoma
Percentage of NHLs	22-30%	33%	<1% adult NHLs 30% childhood NHLs	6%
Genetic Mutation	Bcl-2 activation	Bcl-2, Bcl-6, Myc rearrangements	c-Myc activation	Overexpression of cyclin D1 (Bcl-1 activation)
Classification	Indolent	Aggressive (high-grade)	Very aggressive	Indolent
Risk Factors	Middle-age – elderly	Previous CLL (Richter's transformation: 5% CLL patients progress to DLBCL)	Endemic: African origin, EBV-associated Sporadic: no EBV HIV-related: AIDS-defining illness	Male (M:F=4:1)
Clinical Features	Widespread painless LAD* ± BM involvement Frequent transformation to aggressive lymphoma Very responsive to chemoradiation treatment	Rapidly progressive LAD and extranodal infiltration 50% present at stage I/II, 50% widely disseminated	Endemic form: massive jaw LAD "Starry-sky" histology High-risk of tumour lysis syndrome upon treatment	Often presents as stage IV with palpable LAD Involvement of GI tract (lymphomatous polyposis), Waldeyer's Ring 5 yr survival 25% B symptoms present in ⅓ of patients

Malignant Clonal Proliferations of Mature B-Cells

Table 35. Characteristics of B-Cell Malignant Proliferation

	CLL	Lymphoplasmacytic Lymphoma	Myeloma
Cell Type	Lymphocyte	Plasmacytoid	Plasma cell
Protein	IgM if present	IgM	IgG, A, light chain (rarely M, D, or E)
Lymph Nodes	Very common	Common	Rare
Hepatosplenomegaly	Common	Common	Rare
Bone Lesions	Rare	Rare	Common
Hypercalcemia	Rare	Rare	Common
Renal Failure	Rare	Rare	Common
Immunoglobulin Complications	Common	Rare	Rare

Rouleaux formation on peripheral blood smear, if not artifact, denotes hyperglobulinemia (but not necessarily monoclonality)

Chronic Lymphocytic Leukemia

Definition
- indolent disease characterized by clonal malignancy of mature B-cells

Epidemiology
- most common leukemia in Western world
- mainly older patients; median age 70 yr
- M>F

Pathophysiology
- accumulation of neoplastic lymphocytes in blood, BM, lymph nodes, and spleen

Clinical Features
- 25% asymptomatic (incidental finding)
- 5-10% present with B-symptoms (≥1 of: unintentional weight loss ≥10% of body weight within previous 6 mo, temperature >38°C, or night sweats for ≥2 wk without evidence of infection), extreme fatigue
- lymphadenopathy (50-90%), splenomegaly (25-55%), hepatomegaly (15-25%)
- immune dysregulation: autoimmune hemolytic anemia (DAT positive), ITP, hypogammaglobulinemia ± neutropenia
- BM failure: late, secondary to marrow involvement by CLL cells

Investigations
- CBC: clonal population of B lymphocytes >5 x 10^9/L
- peripheral blood film
  - lymphocytes are small and mature
  - smudge cells
- flow cytometry characteristics of peripheral blood
  - CD5, CD20dim, CD23, light chain restriction
- cytogenetics: FISH (dictates response to therapy and prognosis) imaging must be done post-therapy to ensure post treatment remission

- BM aspirate
  - infiltration of marrow by lymphocytes in 4 patterns: nodular (10%), interstitial (30%), diffuse (35%, worse prognosis), or mixed (25%)

Natural History and Treatment

- natural history: indolent and incurable; most cases show slow progression
- small minority present with aggressive disease; usually associated with chromosomal abnormalities (e.g. p53 deletion)
- first line therapy is dictated by cytogenetic status and patient co-morbidities
  - observation if early, stable, asymptomatic
    - treatment options vary by region; commonly fludarabine + cyclophosphamide + rituximab (FCR) in fit patients age <65, with normal creatinine clearance and lack of 17p deletion/p53 disease
    - chlorambucil (or venetoclax + obinutuzumab in the elderly)
    - ibrutinib or acalabrutinib in patients with unmutated IgVH and/or 17p deletion/p53 positivity
  - autoimmune phenomena: corticosteroids, rituximab
  - radiotherapy for isolated bulky nodes
- molecular therapies
  - idelalisib – PI3K inhibitor
  - ibrutinib, acalabrutinib – BTK (Bruton's tyrosine kinase) inhibitor
  - venetoclax – Bcl-2 inhibitor

Smudge cells are artifacts of damaged lymphocytes from slide preparation

Prognosis

- 9 yr median survival, but varies greatly
- prognosis: Rai staging, Binet staging or Revised CLL International Prognostic Index (includes age >65, Rai/Binet stage, B2M, IGHV mutation status, 17p del or TP53 mutation positivity)

Complications

- BM failure
- immune complications: AIHA, ITP, immune deficiency (hypogammaglobulinemia and impaired T-cell function)
- polyclonal or monoclonal gammopathy (often IgM)
- hyperuricemia with treatment
- 5% undergo Richter's transformation: aggressive transformation to diffuse large B-cell lymphoma (see *Table 35, H50*)

Multiple Myeloma

Definition

- neoplastic clonal proliferation of plasma cells producing a monoclonal immunoglobulin resulting in end organ dysfunction
- usually a single clone of plasma cells, although biclonal myeloma also occurs; rarely non-secretory
- preceded by smoldering myeloma or MGUS

Epidemiology

- incidence 3 in 100000, most common plasma cell malignancy
- increased frequency with age; median age of diagnosis is 68 yr; M>F

Pathophysiology

- malignant plasma cells secrete monoclonal Ab
  - 95% produce M protein (monoclonal Ig = identical heavy chain + identical light chain, or light chains only)
    - IgG 50%, IgA 20%, IgD 2%, IgM 0.5%
    - 15-20% produce free light chains or light chains alone found in either:
      - serum has an increase in the quantity of either kappa or lambda light chain (with an abnormal kappa:lambda ratio)
      - urine has Bence-Jones protein
  - <5% are non-secretors

Multiple Myeloma

SLiM CRAB
Sixty percent plasma cells in BM specimen
Light chain ratio >100
MRI lytic lesion >0.5 cm
Calcium >2.80 mmol/L
Renal failure (Cr >176 mmol/L)
Anemia
Bony lesions (lytic lesions or osteoporosis felt to be caused by myeloma)

Amyloid
The general term for a variety of proteinaceous materials that have a similar structural organization and are abnormally deposited in tissues
Found in a variety of clinical disorders and can cause systemic (e.g. MM (light chains)) or localized amyloidosis (e.g. Alzheimer disease (AB amyloid))

Clinical Features and Complications

- bone disease: pain (usually back), bony tenderness, pathologic fractures
  - lytic lesions are classical (skull, spine, proximal long bones, ribs)
  - increased bone resorption secondary to osteoclast activating factors such as PTHrP
- anemia: weakness, fatigue, pallor
  - secondary to BM suppression
- weight loss
- infections
  - usually *S. pneumoniae* and Gram-negatives
  - secondary to suppression of normal plasma cell function
- hypercalcemia: N/V, confusion, constipation, polyuria, and polydipsia
  - secondary to increased bone turnover

- renal disease/renal failure
  - most frequently causes cast nephropathy (see Nephrology, NP36)
- bleeding
  - secondary to thrombocytopenia, may see petechiae, purpura
  - can also be caused by acquired VWD
- extramedullary plasmacytoma
  - soft tissue mass composed of monoclonal plasma cells, purplish colour
- hyperviscosity: may manifest as headaches, stroke, angina, and MI
  - rare in MM as secondary to increased viscosity caused by IgM protein (more common in WM/LPL)
- amyloidosis
  - accumulation of insoluble fibrillar protein (Ig light chain) in tissues; can cause infiltration of any organ system: cardiac infiltration – diastolic dysfunction, cardiac arrhythmias, syncope, sudden death; GI involvement – malabsorption, beefy large or laterally scalloped tongue; neurologic involvement – orthostatic hypotension, carpal tunnel syndrome
  - may cause Factor X deficiency if fibrils bind Factor X → bleeding (raccoon eyes)
- neurologic disease: muscle weakness, pain, and paresthesias
  - radiculopathy caused by vertebral fracture and extramedullary plasmacytoma
  - spinal cord compression (10-20% of patients) is a medical emergency

Investigations

- CBC
  - normocytic anemia, thrombocytopenia, and leukopenia
  - rouleaux formation on peripheral film
- biochemistry
  - increased Ca^{2+}, increased ESR, decreased anion gap, increased Cr, albumin, β2-microglobulin, and LDH (as part of staging), and proteinuria (24 h urine collection)
- monoclonal proteins
  - SPEP: demonstrates monoclonal protein spike in serum in 80% (i.e. M protein)
  - UPEP: demonstrates light chains in urine = Bence-Jones protein (15% secrete only light chains)
  - immunofixation: demonstrates M protein and identifies Ig type; also identifies light chains
  - serum free light chain quantification: kappa and lambda light chains, calculated ratio
- BM aspirate and biopsy
  - often focal abnormality, greater than 10% plasma cells, abnormal morphology, clonal plasma cells; send for fluorescence in situ hybridization (FISH) or cytogenetics (prognostic implications)
- skeletal series (x-rays), MRI if symptoms of cord compression, PET imaging to pick up lytic lesions in asymptomatic MM
  - presence of lytic lesions and areas at risk of pathologic fracture
  - bone scans are not useful since they detect osteoblast activity
- elevated β2-microglobulin and LDH, and low albumin, are poor prognosticators
  - HBV surface and core Abs, and HBV surface antigen

Diagnosis

- International Myeloma Working Group Criteria ("SLiM CRAB"):
  - ≥60% clonal plasma cells on BM examination
  - light chain ratio (free, involved/uninvolved) of ≥100 in the blood (involved must be at least 100 mg/L)
  - MRI with more than one bone lesion (≥5 mm)
  - CRAB – presence of end-organ damage related to plasma cell dyscrasia, such as:
    - increased serum Ca^{2+}
    - renal failure
    - anemia
    - lytic bone lesions

Treatment

- non-curative
- treatment goals
  - improvement in quality of life (improve anemia, reverse renal failure, prevent fractures)
  - prevention of progression and complications
  - increase overall survival
- autologous transplant if ≤70 yr
  - usually preceded by 4-6 mo of cytoreductive therapy: steroid based with novel agents (i.e. IMIDs or PIs)
- transplant ineligible if >70 yr or comorbidities
  - pending on patient comorbidities can include a combination of: melphalan, prednisone, cyclophosphamide, PI (i.e. bortezomib), IMIDs (revlimid), anti-CD38 agents (e.g. daratumumab)
- supportive management
  - bisphosphonates for those with osteopenia or lytic bone lesions (requires renal dosing)
  - local XRT for bone pain, spinal cord compression
  - kyphoplasty for vertebral fractures to improve pain relief and regain height
  - treat complications: hydration for hypercalcemia and renal failure, bisphosphonates for severe hypercalcemia, prophylactic antibiotics, EPO for anemia, and DVT prophylaxis
- all patients will relapse; choice of retreatment regimen depends on duration of remission, organ involvement, patient's comorbidities, and preferences

Routine urinalysis will not detect light chains as dipstick detects albumin. Need sulfosalicylic acid or 24 h urine protein for immunofixation or electrophoresis

Light Chain Disease

- 15% of MM produce only light chains
- Renal failure is a major problem
- Kappa > lambda light chain has better prognosis

Serum Free Light Chain Ratio is an Independent Risk Factor for Progression in MGUS
Blood 2005;106:812-817
Purpose: To determine whether the presence of monoclonal free kappa or lambda immunoglobulin light chains in MGUS increases the risk of progression to malignancy.
Methods: Retrospective study with median follow-up of 15 yr. Baseline serum samples obtained from 1383 MGUS patients seen at the Mayo clinic between 1960-1994. 1148 baseline samples were obtained within 30 d of diagnosis.
Results: Malignant progression had occurred in 87 (7.6%) patients. In 379 (33%) patients, an abnormal serum free light chain (FLC) ratio was detected. There was a significantly higher risk of progression in patients with an abnormal FLC ratio relative to patients with a normal ratio (hazard ratio, 3.5; 95% CI 2.3-5.5; P<0.001). This finding was independent of the size and type of the serum monoclonal (M) protein. In high-risk MGUS patients (abnormal serum FLC ratio, non-IgG MGUS, high serum M protein level [≥1.5 gm/dL]), the risk of progression at 20 yr was 58% compared to 37% in high-intermediate-risk MGUS (two risk factors), 21% low-intermediate risk (with one risk factor), and 5% low-risk (no risk factors).
Conclusions: The presence of an abnormal FLC ratio is a clinically and statistically significant predictor of progression in MGUS. The low-risk subset of patients with MGUS accounts for 40% of all MGUS patients and have a small lifetime risk of progression, thus less follow-up can be justified.

Prognosis
- International Staging System (ISS) (β2-microglobulin and albumin) used to stage and estimate prognosis
- revised ISS for risk stratification: combination of original ISS, cytogenetic profile (i.e. p53 mutation associated with poor survival and resistance to chemotherapy), and LDH
- median survival based on stage, usually 5-10 yr

Monoclonal Gammopathy of Unknown Significance

Definition
- presence of M protein in serum in absence of any clinical or laboratory evidence of a plasma cell dyscrasia or lymphoproliferative disorders
  - incidence: 0.15% in general population, 5% of people >70 yr
  - asymptomatic

Diagnosis
- presence of a serum monoclonal protein (M protein) at a concentration <30 g/L
- <10% plasma cells in BM
- absence of SLiM CRAB
- 0.3-1% of patients develop a hematologic malignancy each yr
  - patients with M protein peak ≥15 g/L, abnormal free light chain ratio, or patients with IgA or IgM MGUS are at higher risk of malignant transformation
  - patients with abnormal serum free light chains ratio are at increased risk of malignant transformation
- monitor with history q6-12 mo, physical, CBC, Cr, calcium, albumin, LDH, and SPEP (considered pre-malignant)

Lymphoplasmacytic Lymphoma

Definition
- LPL/Waldenstrom's macroglobulinemia
- proliferation of lymphoplasmacytoid cells
  - presence of monoclonal IgM paraprotein

Clinical Features
- chronic disorder of elderly patients; median age 64 yr
- symptoms: weakness, fatigue, bleeding (oronasal), weight loss, recurrent infections, dyspnea, CHF (triad of anemia, hyperviscosity, plasma volume expansion), neurological symptoms, peripheral neuropathy, and cerebral dysfunction
- signs: pallor, splenomegaly, hepatomegaly, lymphadenopathy, and retinal lesions
- key complication to avoid: hyperviscosity syndrome
  - because IgM (unlike IgG) are large and confined mainly to intravascular space

Investigations and Diagnosis
- BM shows plasmacytoid lymphocytes
- bone lesions usually not present
- blood work rarely shows hypercalcemia
- cold hemagglutinin disease possible: Raynaud's phenomenon, hemolytic anemia precipitated by cold weather
- normocytic anemia, rouleaux, and high ESR if hyperviscosity not present
- HBV, HCV serologies (note: can be associated with HCV; HCV eradication can put LPL into remission)

Waldenstrom's macroglobulinemia accounts for 85% of all cases of hyperviscosity syndrome

Treatment
- chemotherapy + rituximab (most commonly bendamustine + rituximab)
- if HCV positive – treat HCV prior to a trial of chemotherapy
- corticosteroids
- plasmapheresis for hyperviscosity: acute reduction in serum IgM

Complications of Hematologic Malignancies

Hyperviscosity Syndrome

Definition
- refers to clinical sequelae of increased blood viscosity (when relative serum viscosity >5-6 units), resulting from increased circulating serum Igs or from increased cellular blood components in hyperproliferative disorders (e.g. multiple myeloma, leukemia, PV)
- Waldenstrom's macroglobulinemia accounts for 85% of cases

Clinical Features
- hypervolemia causing: CHF, headache, lethargy, dilutional anemia
- CNS symptoms due to decreased cerebral blood flow: headache, vertigo, ataxia, and stroke
- retina shows venous engorgement and hemorrhages
- bleeding diathesis
  - due to impaired platelet function, absorption of soluble coagulation factors (e.g. nasal bleeding, oozing gums)
- ESR usually very low

Treatment
- plasmapheresis, chemotherapy

Tumour Lysis Syndrome

Definition
- group of metabolic complications that result from spontaneous or treatment-related breakdown of cancer cells
- more common in diseases with large tumour burden and high proliferative rate (high grade lymphoma, acute leukemia)

Clinical Features
- metabolic abnormalities
  - cells lyse, releasing K^+, uric acid, PO_4^{3-} (increased levels)
  - PO_4^{3-} binds Ca^{2+} (decreased Ca^{2+})
- complications
  - lethal cardiac arrhythmia (increased K^+)
  - acute kidney injury (formerly known as renal failure) see Nephrology, NP21

Treatment
- prevention
  - aggressive IV hydration
  - alkalinization not recommended due to risk of calcium phosphate or xanthine precipitation in renal tubules
  - allopurinol (prevents uric acid accumulation) or rasburicase (lowers existing uric acid)
  - correction of pre-existing metabolic abnormalities
- dialysis

Blood Products and Transfusions

Blood Products

- RBCs, platelets, and coagulation factors (FP, cryoprecipitate, fibrinogen concentrate, factor concentrates) are available for transfusion
- donated blood (1 U = 450-500 mL) is fractionated into these various components
  - centrifugation separates whole blood into RBCs and plasma
  - plasma is further fractionated
    - need to pool multiple units of platelets and WBCs to obtain therapeutic amounts
    - FP (previously known as FFP) is plasma frozen within 24 h of collection
    - cryoprecipitate is the high MW precipitate generated when FP is thawed at low temperatures
  - single donor platelets and plasma can also be obtained by apheresis donations

Specialized Products
- irradiated blood products
  - prevent proliferation of donor T-cells in recipients at risk of GVHD
  - used for patients with severe T-cell immunodeficiency, on purine analogue chemotherapy, with Hodgkin lymphoma, candidates for BM transplant, or receiving directed transfusions from first-degree relatives, HLA-matched products, or intrauterine transfusions
- CMV-negative blood products
  - seronegative pregnant women
  - intrauterine transfusions

Blood Groups

Group	Antigen (on RBC)	Antibody (in serum)
O	H	Anti-A, anti-B
A	A	Anti-B
B	B	Anti-A
AB	A and B	Nil

In Canada, blood products are leukodepleted via filtration immediately after donation; therefore it is considered:
- Low in lymphokines, resulting in a lower incidence of febrile nonhemolytic transfusion reactions
- CMV safe (because CMV is found in leukocytes)

Red Blood Cells

Packed Red Blood Cells
- stored at 4°C
- shelf life is 42 d after collection
- infuse each unit over 2 h (max of 4 h)

1 unit of pRBC will increase Hb by approximately 10 g/L

Indications for Packed RBC Transfusion

- Hb <70 g/L; this may change as per patient's tolerance or symptoms
  - maintain Hb between 70 and 90 g/L during active bleeds
- consider maintaining a higher Hb for patients with:
  - CAD/unstable coronary syndromes
  - uncontrolled, unpredictable bleeding

American Society of Hematology Choosing Wisely Recommendation
Do not transfuse more than the minimum number of RBC units necessary to relieve symptoms of anemia or to return the patient to a safe Hb range (70-80 g/L) in stable non-cardiac patients

Selection of Red Cells for Transfusion

- when anticipating an RBC transfusion, the following should be ordered:
  - group and screen: determines the blood group and Rh status of the recipient as well as the presence of auto- or alloantibodies against major/minor blood group antigens in the patient's plasma
  - cross-match: involves mixing the recipient's blood with potential donor blood and looking for agglutination (takes 30-45 min)
- when blood is required, several options are available
  - 1st-line: fully crossmatched blood, electronic crossmatch is becoming more widely used (not always available in emergency situations)
  - 2nd-line: donor blood of the same group and Rh status as the recipient
  - 3rd-line: O- blood for females of reproductive age; O +blood for all others

Platelets

Table 36. Platelet Products

Product	Indication
Random Donor (Pooled)	Thrombocytopenia with bleeding
Single Donor Platelets	Potential BMT recipients. Refractory to pooled platelets
HLA Matched Platelets	Refractory to pooled or single donor platelets, presence of HLA Abs

See Landmark Hematology Trials for more information on the FOCUS trial. It details the efficacy of liberal or restrictive transfusion in high-risk patients after hip surgery

- stored at 20-24°C
- random donor platelets come in a pool of 4 units; while a unit of apheresis platelets comes from a single donor
- 1 platelet pool should increase the platelet count by ≥15 x 10^9/L
- if an increase in the platelet count is not seen post-transfusion: autoantibodies (i.e. ITP), alloantibodies (Anti-HLA or Anti-HPA), consumption (bleeding, sepsis, DIC), or hypersplenism may be present

Table 37. Indications for Platelet Transfusion

Plt (x 10^9/L)	Indications
<10	Non-immune thrombocytopenia
<20	Procedures not associated with significant blood loss
<50	Procedures associated with blood loss or major surgery (>500 mL estimated blood loss)
<100	Pre-neurosurgery or head trauma
Any	Platelet dysfunction (or antiplatelet agents) and marked bleeding

Relative Contraindications of Platelet Transfusion

- TTP, HIT, post-transfusion purpura, and HELLP

Coagulation Factors

Table 38. Coagulation Factor Products

Product	Indication
FP	Depletion of multiple coagulation factors (e.g. sepsis, DIC, dilution, TTP/HUS, liver disease), emergency reversal of life-threatening bleeding secondary to warfarin overdose when factor concentrates are not available
Cryoprecipitate (enriched fibrinogen, VWF, VIII, XIII)	Hemophilia A (Factor VIII deficiency) and von Willebrand disease – use in emergencies when specific factor concentrates are not available Hypofibrinogenemia
Fibrinogen Concentrate (FC)	Hypofibrinogenemia
Humate P or Wilate	von Willebrand disease and Hemophilia A
Factor VIII concentrate	Factor VIII deficiency (Hemophilia A)
Factor IX concentrate	Factor IX deficiency (Hemophilia B)
Recombinant factor VIIa	Factor VII deficiency with bleeding/surgery, Hemophilia A or B with inhibitors, Glanzmann's thrombasthenia
Prothrombin complex concentrate; PCC (Octaplex®, Beriplex®)	Reversal of warfarin therapy or vitamin K deficiency in bleeding patient or in patient requiring urgent (<6 h) surgical procedure, urgent non-specific "reversal" of direct Xa inhibitors
Activated prothrombin complex concentrate; aPCC (FEIBA)	Hemophilia A or B with inhibitors

Group & Screen vs. Cross-Matching:
G&S: ABO group + Rh factor
Cross-Matching: match recipient's serum with donor's packed RBC or Abs

Acute Blood Transfusion Reactions

DDx of Post-Transfusion Fever
Acute hemolytic transfusion reaction
Febrile non-hemolytic transfusion reaction (FNHTR)
Bacterial contamination
Allergy

DDx of Post-Transfusion Dyspnea
Transfusion-associated circulatory overload (TACO)
Transfusion-related acute lung injury (TRALI)
Allergy (bronchospasm/anaphylaxis)

IMMUNE

Acute Hemolytic Transfusion Reactions
- ABO incompatibility resulting in intravascular hemolysis secondary to complement activation, occurs immediately after transfusion
- most commonly due to incorrect patient identification
- risk per unit of blood is <1/40000
- presentation: fever, chills, hypotension, back or flank pain, dyspnea, hemoglobinuria
- acute renal failure (<24 h) and DIC
- treatment
  - stop transfusion
  - notify blood bank and check for clerical error
  - send new specimen to blood bank for repeat testing and draw hemolysis labs: CBC, bilirubin, LDH, reticulocytes, DAT
  - maintain BP with vigorous IV fluids ± inotropes
  - maintain urine output with diuretics, crystalloids, dopamine

Febrile Nonhemolytic Transfusion Reactions
- due to alloantibodies to WBC, platelets, or other donor plasma antigens, and release of cytokines from blood product cells
- occurs within 6 h of transfusion
- risk per unit of blood is 1/100 (minor), 1/10000 to 40000 (severe)
- presents with fever ± rigors, facial flushing, headache, myalgia
- look for serious symptoms of shaking, chills/rigors, hypotension, tachycardia, anxiety, dyspnea, back/chest pain, N/V
- treatment
  - rule out hemolytic reaction or infection
  - if temperature <39°C and no serious symptoms, continue with transfusion but decrease rate and give antipyretics
  - if temperature ≥39°C or presence of serious symptoms, stop transfusion, investigate the reaction, and start supportive measures

Allergic Nonhemolytic Transfusion Reactions
- alloantibodies (IgE) to proteins in donor plasma result in mast cell activation and release of histamine
- occurs mainly in those with history of multiple transfusions or multiparous women
- risk per unit of blood is 1/100
- presents mainly as urticaria and occasionally with fever
- can present as anaphylactoid reaction with bronchospasm, laryngeal edema, and hypotension (1/40000)
- can occur in some IgA deficient patients with anti-IgA
- treatment
  - mild: slow transfusion rate and give diphenhydramine
  - moderate to severe: stop transfusion, give IV diphenydramine, steroids, epinephrine, IV fluids, and bronchodilators

Transfusion-Related Acute Lung Injury
- new-onset acute lung injury that occurs during transfusion or within 6 h of transfusion completion
  - profound hypoxemia (PaO_2/FiO_2 <300 mmHg)
  - bilateral pulmonary edema on imaging
  - no clinical evidence of left atrial hypertension or if present, judged not to be the main contributor
- pathogenesis uncertain; perhaps due to binding of donor Abs to WBC of recipient and release of mediators that increase capillary permeability in the lungs
- typically occurs 2-4 h post-transfusion and resolves in 24-72 h
- risk per unit of blood is 1/10000
  - is currently the leading cause of transfusion-related morbidity and mortality
- treatment: supportive therapy (oxygen)
- inform blood bank; patient and donor testing will be arranged

NONIMMUNE

Transfusion-Associated Circulatory Overload
- due to impaired cardiac function and/or excessively rapid transfusion
- presentation: dyspnea, orthopnea, hypertension, tachycardia, crackles at base of lungs, and increased venous pressure
- incidence: 1/100
- risk factors: age >70 yr, heart failure, history of MI, renal failure, positive fluid balance
- treatment: stop transfusion, give diuretics, and oxygen. Transfuse at lower rate ± diuretics to prevent

Bacterial Infection
- Gram-positive: *S. aureus, S. epidermidis, Bacillus cereus*
- Gram-negative: *Klebsiella, Serratia, Pseudomonas, Yersinia*
- overall risk is 1/100000 for RBC and 1/10000 for platelets
- never store blood >4 h after bag has left blood bank
- treatment: stop transfusion, blood cultures, IV antibiotics, fluids

Hyperkalemia
- due to K^+ release from stored RBC
- risk increases with storage time and if blood is irradiated; decreases with fresh blood
- occurs in 5% of massively transfused patients
- treatment: see Nephrology, NP15

Citrate Toxicity
- occurs with massive transfusion and in patients with liver disease – patients are unable to clear citrate from blood
- citrate binds to Ca^{2+} and causes signs and symptoms of hypocalcemia and exacerbates coagulopathy
- treatment: IV calcium gluconate 1 g

Dilutional Coagulopathy
- occurs with massive transfusion (>10 units)
- pRBC contains no coagulation factors, fibrinogen, cryoprecipitate, or platelets
- treatment: FP, cryoprecipitate, and platelets

Delayed Blood Transfusion Reactions

IMMUNE

Delayed Hemolytic
- due to alloantibodies to minor antigens such as Rh, Kell, Duffy, and Kidd
- level of Ab at time of transfusion is too low to be detected and to cause hemolysis; Ab levels increase later due to secondary stimulus and causes extravascular hemolysis
- occurs 3-14 d after transfusion
- presentation: anemia and mild jaundice
- treatment: no specific treatment required; important to note for future transfusion
- N.B. serologic transfusion reactions are the development of alloantibodies in the absence of frank hemolysis

Allogeneic SCT GVHD
To reduce risk of GVHD development after allogeneic SCT, administer inhibitors of T-cell activation, including cyclosporin A or tacrolimus

Transfusion-Associated Graft Versus Host Disease
- transfused T-lymphocytes recognize and react against "host" (recipient)
- occurs 4-30 d following transfusion
- most patients already have severely impaired immune systems (e.g. Hodgkin lymphoma or leukemia)
- presentation: fever, diarrhea, liver function abnormalities, and pancytopenia
- can be prevented by giving irradiated blood products

NONIMMUNE

Iron Overload
- due to repeated transfusions over long period of time (e.g. β-thalassemia major)
- can cause secondary hemochromatosis
- treatment: iron chelators or phlebotomy if no longer requiring blood transfusion and not anemic

Viral Infection Risk
- HBV 1/7000000
- HCV 1/12000000
- HIV 1/20000000
- Human T-lymphotropic virus (HTLV) 1/600000000
- other infections include EBV, CMV, WNV (West Nile virus)

Common Medications

Antiplatelet Therapy

• see *Figure 12a, H27*

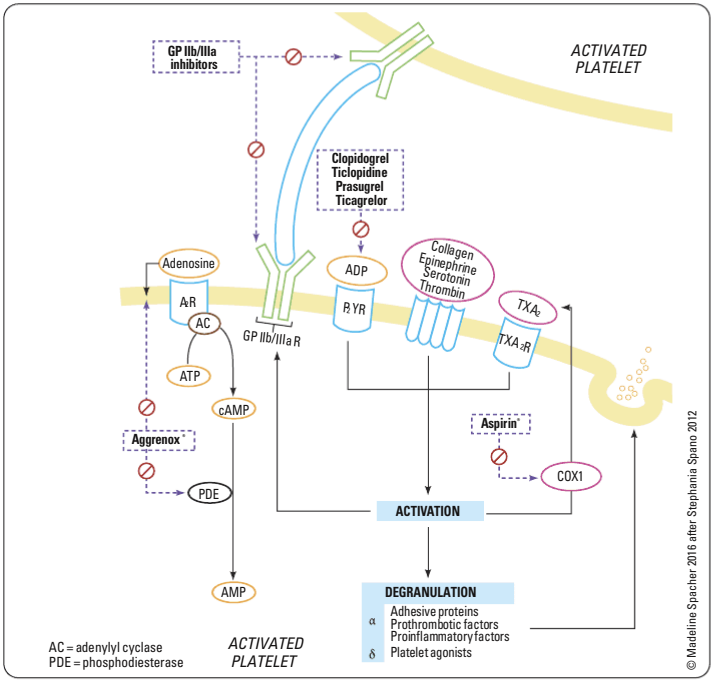

Figure 17. Mechanisms of action of antiplatelet therapy

Table 39. Antiplatelet Therapy

	Mechanism of Action	Typical Dose/ Route of Administration	Onset/Peak/ Duration	Specific Side Effects	Remarks
Aspirin® (ASA)	Irreversibly acetylates COX, inhibiting thromboxane A2 (TXA2) synthesis, thus inhibiting platelet aggregation	Single loading 200-300 mg PO, followed by dose of 75-100 mg PO daily	Onset: 5-30 min Peak: 0.25-3 h Duration: 3-6 h (platelet inhibition lasts 7-10 d)	GI ulcer/bleeding Tinnitus Bronchospasm Angioedema Reye's syndrome in pediatric patients	Indicated for stroke/MI prophylaxis Reduce incidence of recurrent MI Decrease mortality in post-MI patients Contraindicated in patients with GI ulcers
Aggrenox® (ASA + Dipyridamole)	Dipyridamole increases intracellular cAMP levels, which inhibits TXA2 synthesis, leading to decreased platelet aggregation	1 capsule PO BID	Peak: 75 min	H/A Dyspepsia N/V Abdominal pain Cardiac failure Hemorrhoids	More effective than ASA in secondary prevention of stroke Dipyridamole potentiates antiplatelet action of ASA
Clopidogrel (Plavix®)	Irreversibility inhibits ADP binding to platelets, thus decreasing platelet aggregation	Loading dose 300 mg PO, then 75 mg daily	Onset: 2 h (loading dose) Peak: 6 h (loading dose) Duration: 5 d	URI Chest pain H/A Flu-like syndrome Depression UTI GI hemorrhage Pancytopenia May cause TTP	Prevention of cardiovascular events in high-risk patients Clopidogrel is a prodrug requiring two-step activation to active metabolite CYP2C19 poor metabolizers have diminished response to clopidogrel Caution with hepatic/renal impairment
Prasugrel (Effient®)	Same as clopidogrel	Loading dose 60 mg, then 5-10 mg PO daily	Onset: 30 min (loading dose) Peak: 4 h (loading dose) Duration: 5-10 d	Dizziness H/A Nervousness Blurry vision	Alternative to clopidogrel for prevention of cardiovascular events in high-risk patients Higher potency compared to clopidogrel No significant drug-drug interactions, although more data is required

Table 39. Antiplatelet Therapy

	Mechanism of Action	Typical Dose/ Route of Administration	Onset/Peak/ Duration	Specific Side Effects	Remarks
Ticagrelor (Brilinta®)	Reversibly inhibits ADP binding to platelets	Loading dose 180 mg, then 90 mg PO BID	Onset: 30 min (loading dose) Peak: 1.5 h for prodrug, 2.5 h for active metabolite	Difficulty or laboured breathing Shortness of breath Tightness in chest Dizziness	Alternative to clopidogrel for prevention of cardiovascular events in high-risk patients Higher potency compared to clopidogrel Ticagrelor does not need metabolic activation to serve its antiplatelet function Drug-drug interactions with CYP3A4 inhibitors and inducers Prasugrel is a prodrug requiring metabolic activation mainly by CYP3A5 and CYP2B6
Glycoprotein IIb/IIIa Inhibitors Reopro® (abciximab), Integrilin® (eptifibatide)	Blocking GPbII/IIIa receptor inhibits fibrinogen and VWF binding, leading to decreased platelet aggregation	Variable IV	Variable	Hypotension Back pain N/V Chest pain Abdominal pain Thrombocytopenia	Used most commonly in cardiac catheterization Contraindicated in PUD Monitoring aPTT/activated clotting time

Anticoagulant Therapy

Table 40. Anticoagulant Therapy

	Mechanism of Action	Dose/Route of Administration	Onset/Peak/ Duration	Reversing Agent	Monitoring	Specific Side Effects	Remarks
Heparin	Inhibition of Factor Xa and Factor IIa, mediated via antithrombin	Variable, depends on indication; can be used IV or SC	Onset: Immediate (IV); 20-30 min (SC)	Protamine sulfate	aPTT (intrinsic pathway), UFH (anti-Xa) levels	Hemorrhage HIT Increased liver enzymes	Pregnancy: safe (does not cross placenta)
Warfarin	Vitamin K antagonist: inhibits production of Factors II, VII, IX, X, proteins C and S	Individualized dosing by monitoring PT/INR; PO	Onset: 24-72 h Peak: 5-7 d Duration: 2-5 d	Vitamin K PCC FP	INR: maintain 2-3 (2.5-3.5 for certain mechanical valves)	Hemorrhage Cholesterol embolism syndrome Intraocular hemorrhage	Pregnancy: not used, can cross placenta (teratogenic)
LMWH (enoxaparin, dalteparin, tinzaparin)	Mainly Factor Xa inhibition, some FIIa inhibition, both mediated via antithrombin	Variable, weight-based dose, depends on indication; SC/IV	Onset: 1-2 h Peak: 3-5 h Duration: 12-24 h	Partial reversibility with protamine sulfate	Anti-Xa levels in pediatrics, extremes of weight, or renal insufficiency	Hemorrhage Fever Increased liver enzymes <1% HIT	Higher bioavailability than heparin Can accumulate in patients with low CrCl (<30 mL/min) Standard treatment of VTE in pregnancy and patients with malignancy
Fondaparinux	Selective Factor Xa inhibition, mediated via antithrombin	Variable SC daily	Onset: 2 h Peak: 2-3 h	Not reversible	None	Anemia Fever Nausea Rash	Long half-life (17-21 h) Contraindicated in renal failure
Rivaroxaban	Direct Factor Xa inhibitor	Variable, depends on indication; PO	Onset: 1-3 h Peak: 1-3 h	Andexanet α	Anti-Xa levels validated for rivaroxaban may be used to detect presence of drug only	Syncope GI hemorrhage Menorrhagia Gastroentritis Cough	Indicated for treatment of acute VTE, secondary VTE prevention, thromboprophylaxis in orthopedic patients and stroke prophylaxis in non-valvular AFib; ensure CrCl>30 mL/min; must be taken with food; contraindicated in mechanical heart valves
Apixaban	Direct Factor Xa inhibitor	PO BID	Onset: 1-3 h Peak: 1-3 h	Andexanet α	Anti-Xa levels validated for apixaban may be used to detect presence of drug only	Hemorrhage Nausea Anemia	Indicated for treatment of acute VTE, secondary VTE prevention, thromboprophylaxis in orthopedic patients and stroke prophylaxis in non-valvular AFib; ensure CrCl >25 ml/min; contraindicated in mechanical heart valves
Edoxaban	Direct Factor Xa inhibitor	PO daily	Onset: 1-2 h Peak: 1-2 h	Andexanet α	Not typically available	Hemorrhage Rash	Indicated for treatment of acute VTE, secondary VTE prevention, stroke prophylaxis in non-valvular AFib; contraindicated in mechanical heart valves; dose reduction in renal insufficiency, avoid in CrCl <15 mL/min
Argatroban	Direct thrombin inhibitor	Variable IV	Onset: 5-10 min Duration: 20-40 min	Not reversible	aPTT	Dyspnea Hypotension Fever	Indicated for treatment of heparin-induced thrombocytopenia, PCI; contraindicated in mechanical heart valves
Dabigatran	Direct thrombin inhibitor	150 mg PO BID	Onset: 1-3 h Peak: 1-3 h	Idarucizumab	Dilute thrombin time may be used to detect presence of drug only; TT also sensitive for drug presence	GI upset Dyspepsia	Indicated for treatment of acute VTE (after 5-10 d parenteral therapy), secondary VTE prevention, thromboprophylaxis in orthopedic patients and stroke prophylaxis in non-valvular AFib; ensure CrCl >30 mL/min; should be stored in original packaging; contraindicated in mechanical heart valves

Adverse Reactions to Heparin

- hemorrhage: depends on dose, age, and concomitant use of antiplatelet agents or thrombolytics
- HIT a hematologic emergency associated with venous or arterial thrombosis (see *Table 22, H30*)
- osteoporosis: with long-term use

Low Molecular Weight Heparin (enoxaparin, dalteparin, tinzaparin)

- increased bioavailability compared to unfractionated heparin
- increased duration of action
- SC route of administration

- do not need to monitor aPTT
- adverse reactions less common than UFH
- patients with renal failure (CrCl <30 mL/min) can accumulate LMWH, therefore may need to adjust dose
- only partially reversible with protamine sulfate
- HIT is less common

Table 41. Recommended Management of a Supratherapeutic INR

INR	Bleeding Present	Recommended Action
>Therapeutic to 4.5	No	Lower warfarin dose or omit a dose and resume warfarin at a lower dose when INR is in therapeutic range or no dose reduction needed if INR is minimally prolonged
>4.5 to 10.0	No	Omit the next 1-2 doses of warfarin, monitor INR more frequently and resume treatment at a lower dose when INR is in therapeutic range OR omit a dose and administer oral vitamin K 1-2.5 mg in patients with increased risk of bleeding
>10.0	No	Hold warfarin and administer oral vitamin K 2.5 to 5 mg; monitor INR more frequently and administer more vitamin K as needed; resume warfarin at a lower dose when INR is in therapeutic range
Any	Serious or life threatening	Hold warfarin and administer vitamin K 10 mg by slow IV infusion; supplement with four-factor prothrombin complex concentrate; monitor and repeat as needed

Adapted from: American College of Chest Physicians Evidence-Based Clinical Practice Guidelines. Chest 2012;(2 suppl):e152S

Chemotherapeutic and Biologic Agents Used in Oncology

Table 42. Selected Chemotherapeutic and Biologic Agents

Class	Example	Mechanism of Action or Target
Alkylating Agent	chlorambucil, cyclophosphamide, melphalan (nitrogen mustards) carboplatin, cisplatin dacarbazine, procarbazine busulfan bendamustine	Damage DNA via alkylation of base pairs Leads to cross-linking of bases, abnormal base-pairing, DNA breakage
Antimetabolites	methotrexate (folic acid antagonist) 6-mercaptopurine, fludarabine (purine antagonist) 5-fluorouracil (5-FU) (pyrimidine antagonist) hydroxyurea cytarabine	Inhibit DNA synthesis
Antibiotics	adriamycin (anthracycline) bleomycin mitomycin C daunorubicin	Interfere with DNA and RNA synthesis
Taxanes	paclitaxel docetaxel	Stabilize microtubules against breakdown once cell division complete
Vinca-alkaloids	vinblastine vincristine vinorelbine	Inhibit microtubule assembly (mitotic spindles), blocking cell division
Topoisomerase Inhibitors	irinotecan, topotecan (topo I) etoposide (topo II)	Interfere with DNA unwinding necessary for normal replication and transcription
Steroids	prednisone dexamethasone	Immunosuppression
Purine Analogues	fludarabine cladribine	Interferes with DNA synthesis
Monoclonal Antibodies	trastuzumab (Herceptin®) bevacizumab (Avastin®) rituximab (Rituxan®), ofatumumab (Arzerra®), obinutuzumab (Gayzva®) cetuximab (Erbitux®) daratumumab	HER2 antagonist VEGF antagonist CD20 antagonist EGFR antagonist CD38 antagonist
Small Molecule Inhibitors	imatinib mesylate (Gleevec®) dasatinib nilotinib bosutinib erlotinib (Tarceva®) gefitinib (Iressa®) bortezomib (Velcade®) sunitinib (Sutent®) ibrutinib (Imbruvica®) idealasib (Zyedlig®) ruxolitinib (Jakavi®) venetoclax lenalidomide, pomalidomide	BCR-ABL inhibitor BCR-ABL inhibitor BCR-ABL inhibitor BCR-ABL inhibitor EGFR antagonist EGFR antagonist 26S proteasome inhibitor VEGFR, PDGFR antagonist BTK inhibitor P13K inhibitor JAK2 inhibitor BCR-ABL inhibitor Bcl-2 inhibitor Immunomodulators
CAR T cell therapy	tisagenlecleucel (Kymriah®) axicabtagene ciloleucel (Yescarta®)	Target CD19

Landmark Hematology Trials

Trial Name	Reference	Clinical Trial Details
Hematologic Malignancies and Related Disorders		
Long-term outcomes of imatinib treatment for chronic myeloid leukemia	NEJM 2017;376:917-927	**Title**: Long-Term Outcomes of Imatinib Treatment for Chronic Myeloid Leukemia **Purpose**: To compare the efficacy of imatinib with that of IFN-α plus low-dose cytarabine in newly diagnosed chronic-phase CML. **Methods**: 1106 patients with Ph-positive CML in the chronic phase were randomized 1:1 to imatinib or interferon α plus cytarabine. Crossover to imatinib were allowed if no response by 6 mo or major cytogenetic response by 12 mo. **Results**: Assessing the imatinib arm after a median of 11 yr of follow-upspecifically at the sixth year point, the complete cytogenetic response rate was 83%. Among patients who attained a major molecular response after 18 mo of imatinib therapy, the overall survival at 10 yr was 93% and freedom from CML-related death 100%. **Conclusions**: This 116-year update of IRIS demonstrates the efficacy and safety of imatinib as first-line therapy for CML patients.
Ibrutinib Versus Ofatumumab in Previously Treated Chronic Lymphoid Leukemia. Byrd et al. 2014	NEJM 2014;371:213-23	**Title**: Ibrutinib Versus Ofatumumab in Previously Treated Chronic Lymphoid Leukemia **Purpose**: To evaluate the efficacy of ibrutinib in patients with CLL and small lymphocytic lymphoma (SLL) at risk for poor outcomes. **Methods**: 391 patients with relapsed or refractory CLL or SLL were randomly assigned to daily ibrutinib or ofatumumab. **Results**: Ibrutinib significantly improved progression-free survival (hazard ratio, 0.22; P<0.001), overall survival (0.43; P=0.005) with a higher overall response rate (42.6% vs. 4.1%, P<0.001) as compared with patients on ofatumumab. Overall survival was 90% in the ibrutinib group and 81% in the ofatumumab group at 12 mo. **Conclusion**: Ibrutinib significantly improved progression-free survival, overall survival, and response rate among patients with previously treated CLL or SLL.
POLLUX	NEJM 2016;375:1319-31	**Title**: Daratumumab, Lenalidomide, and Dexamethasone for Multiple Myeloma **Purpose**: To assess if daratumumab lengthens PFS when added to lenalidomide and dexamethasone therapy in patients with relapsed or refractory myeloma. **Methods**: 569 patients with MM who had been previously treated were randomly assigned to either lenalidomide and dexamethasone (control group) or daratumumab plus lenalidomide and dexamethasone (daratumumab group). The primary endpoint was PFS. **Results**: PFS at 12 mo was 83.2% in the daratumumab group and 60.1% in the control group. Daratumumab had a significantly higher overall response as compared to the control group (P <0.001). Neutropenia was more frequent in the daratumumab group (51.9% vs. 37.0%). **Conclusion**: PFS was significantly lengthened by addition of daratumumab to lenalidomide and dexamethasone for patients with relapsed or refractory MM but was associated with higher rates of neutropenia.
GALLIUM	NEJM 2017;377:1331-44	**Title**: Obinutuzumab for the First-Line Treatment of Follicular Lymphoma **Purpose**: To compare rituximab-based chemotherapy with obinutuzumab-based chemotherapy in patients with untreated advanced-stage follicular lymphoma. **Methods**: 1202 patients were randomly assigned to receive induction treatment with obinutuzumab-based chemotherapy (obinutuzumab) or rituximab-based chemotherapy (rituximab). **Results**: Risk of progression, relapse, or death was significantly lower on obinutuzumab vs.rituximab (estimated 3-yr PFS, 80.0% vs. 73.3%; hazard ratio for progression, relapse, or death, 0.66; 95% CI, 0.51-0.85; P=0.001). There were more adverse events in the obinutuzumab group (grade 3-5: 74.6% vs. 67.8%; serious events: 46.1% vs. 39.9%). **Conclusion**: Obinutuzumab-based chemotherapy resulted in longer PFS than rituximab-based therapy but more frequent high-grade adverse events.
Long-Term Follow-up of CD19 CAR Therapy in Acute Lymphoblastic Leukemia. Park et al. 2018	NEJM 2018;378:449-59	**Title**: Long-Term Follow-up of CD19 CAR Therapy in Acute Lymphoblastic Leukemia **Purpose**: To investigate the use of CAR-T in relapsed B-cell ALL. **Methods**: Phase 1 trial including 53 adults with relapsed B-cell ALL received an infusion of autologous T cells expressing the 19-28z CAR. **Results**: Severe cytokine release syndrome occurred in 26% of patients following infusion (95% CI, 15-40); 1 patient died. 83% of patients experienced complete remission. At median 29 mo follow-up, median overall survival was 12.9 mo (8.7-23.4) and median event-free survival was 6.1 mo (5.0-11.5). **Conclusion**: Median overall survival was 12.9 mo in the entire cohort. More adverse events occurred in patients with high disease burden.
Thrombosis		
CLOT	NEJM 2003;349:146-53	**Title**: Low-Molecular-Weight Heparin Versus a Coumarin for the Prevention of Recurrent Venous Thromboembolism in Patients with Cancer **Purpose**: To compare the efficacy of LMWH with an oral anticoagulant for preventing recurrent thrombosis in cancer patients. **Methods**: Cancer patients with acute, symptomatic proximal DVT, PE, or both were randomly assigned to dalteparin (LMWH) for 5-7 d plus a coumarin derivative for 6 mo or dalteparin alone for 6 mo. **Results**: At 6 mo, the rate of recurrent thromboembolism was 17% in the oral-anticoagulant group and 9% in the dalteparin group. Rates of major bleeding were not significantly different between groups (6% vs. 4%, respectively); any bleeding (14% vs. 19%). **Conclusions**: Dalteparin was superior to an oral anticoagulant in cancer patients for reducing recurrent thromboembolism rates without increasing bleeding risk
Influence of Preceding Length of Anticoagulant Treatment and Initial Presentation of Venous Thromboembolism on Risk of Recurrence After Stopping Treatment: Analysis of Individual Participants' Data From Seven Trials. Boutitie et al. 2011	BMJ 2011;342:d3036	**Title**: Influence of Preceding Length of Anticoagulant Treatment and Initial Presentation of Venous Thromboembolism on Risk of Recurrence After Stopping Treatment: Analysis of Individual Participants' Data From Seven Trials **Purpose**: To determine how length of anticoagulation of VTE influences recurrence risk after treatment is stopped. CAR: Individual participants' data was pooled from 7 RCTs including 2925 men or women with a first VTE who did not have cancer and had varying durations of anticoagulant treatment. **Results**: Recurrence was higher if anticoagulation was stopped at 1-1.5 mo vs. at ≥3 mo (hazard ratio 1.52, 1.14-2.02) and similar if treatment was stopped at 3 mo vs. ≥6 mo (1.19, 0.86-1.65). **Conclusion**: Risk of recurrent VTE was similar when anticoagulation was stopped after 3 mo vs. stopping after a longer course of treatment.
EINSTEIN-PE	NEJM 2012;366:1287-97	**Title**: Oral Rivaroxaban for the Treatment of Symptomatic Pulmonary Embolism **Purpose**: To investigate the efficacy and safety of a fixed-dose rivaroxaban regimen for the treatment of PE. **Methods**: 4832 patients who had acute symptomatic PE ± DVT were randomly assigned to rivaroxaban or standard therapy with enoxaparin followed by a vitamin K antagonist. **Results**: Rivaroxaban was noninferior to standard therapy for the primary efficacy outcome (symptomatic recurrent VTE), 2.1% in rivaroxaban vs. 1.8% in standard-therapy (hazard ratio, 1.12; 95% CI, 0.75-1.68). Clinically relevant bleeding occurred in 10.3% of patients on rivaroxaban and 11.4% of those on standard-therapy (0.90; 0.76-1.07; P=0.23). **Conclusion**: For initial and long-term treatment of PE, fixed-dose rivaroxaban alone was noninferior to standard therapy with a potentially better benefit-risk profile.

Trial Name	Reference	Clinical Trial Details
AMPLIFY	NEJM 2013;369:799-808	**Title**: Oral Apixaban for the Treatment of Acute Venous Thromboembolism **Purpose**: To investigate the efficacy and safety of fixed-dose apixaban for the treatment of VTE. **Methods**: 5395 patients with acute VTE were randomly assigned to receive apixaban or conventional therapy (SC enoxaparin, followed by warfarin). **Results**: Apixaban was noninferior to conventional therapy for the primary efficacy outcome (symptomatic recurrent VTE or death from VTE) (P<0.001). Major bleeding or clinically relevant nonmajor bleeding occurred in 4.3% of patients on apixaban vs. 9.7% of those on conventional-therapy (RR, 0.44; 95% CI, 0.36-0.55; P<0.001). **Conclusion**: For the treatment of acute VTE, fixed-dose apixaban alone was noninferior to conventional therapy with significantly less bleeding.
RE-VERSE AD	NEJM 2015;373:511-20	**Title**: Idarucizumab for Dabigatran Reversal **Purpose**: To investigate the efficacy and safety of idarucizumab for reversing the anticoagulant effects of dabigatran. **Methods**: 90 patients with either a serious bleed or one requiring an urgent procedure secondary to dabigatran received idarucizumab. **Results**: Idarucizumab normalized test results in 88-98% of patients, which was evident within minutes. Unbound dabigatran concentrations remained <20 ng/mL at 24 h in 79% of patients. **Conclusion**: The anticoagulant effect of dabigatran was completely reversed by idarucizumab within minutes.
CACTUS	Lancet Haematol 2016;3:e556-e562	**Title**: Anticoagulant Therapy for Symptomatic Calf Deep Vein Thrombosis (CACTUS): A Randomised, Double-Blind, Placebo-Controlled Trial **Purpose**: To investigate the efficacy and safety of anticoagulant treatment in patients with acute symptomatic DVT of the calf. **Methods**: 259 low-risk outpatients without active cancer or previous VTE with a first acute symptomatic calf DVT were randomly assigned to receive either nadroparin (LMWH) or placebo for 6 wk. **Results**: No significant difference between groups was seen in the composite primary outcome (extension of calf DVT to proximal veins, contralateral proximal DVT, and symptomatic pulmonary embolism at day 42). Bleeding occurred in 4% of patients on nadroparin and no patients on placebo (risk difference 4.1, 95% CI 0.4-9.2; p=0.0255). **Conclusion**: In low-risk outpatients with symptomatic calf DVT, nadroparin was non-superior to placebo in reducing the risk of proximal extension or VTE, but it did increase bleeding risk.
Blood Products and Transfusion		
FOCUS	NEJM 2011;365:2453-2462	**Title**: Liberal or Restrictive Transfusion in High-Risk Patients after Hip Surgery (FOCUS) **Purpose**: To determine whether a higher threshold for blood transfusion would improve recovery in patients who had undergone surgery for hip fracture. **Methods**: 2016 patients >50 yr with a history of or risk factors for cardiovascular disease and Hb level below 10 g/dL after hip-fracture surgery were randomly assigned to a liberal transfusion strategy (a Hb threshold of 10 g/dL) or a restrictive transfusion strategy (anemia symptoms or at physician discretion for a Hb level less than 8 g/dL). **Results**: The primary outcome was death or inability to walk across a room without human assistance on a 60 d follow-up. Primary outcome rates were 35.2% in the liberal transfusion strategy group and 34.7% in the restrictive transfusion strategy group. Rates of complications were similar in the two groups. **Conclusion**: A liberal transfusion strategy did not reduce mortality rates or the inability to walk independently on 60 d follow-up compared to a restrictive transfusion strategy in elderly patients with high cardiovascular risk factors after hip surgery.
TRICC BP	NEJM 1999;340:409-17	**Title**: A Multicenter, Randomized, Controlled Clinical Trial of Transfusion Requirements in Critical Care. Transfusion Requirements in Critical Care Investigators, Canadian Critical Care Trials Group **Purpose**: To determine if equivalent results can be achieved by a restrictive strategy of red-cell transfusion and a liberal strategy in critically ill patients. **Methods**: 838 critically ill patients with euvolemia (after initial treatment and Hb <9 g/dL within 72 h of ICU admission) received either (1) a restrictive strategy (transfusion if Hb <7.0 g/dL, maintained at 7-9 g/dL) or (2) a liberal strategy (transfusions if Hb <10.0 g/dL, maintained at 10-12 g/dL). **Results**: Mortality rates at 30 d were similar between groups. However, among less acutely ill patients and those <55 yr of age, mortality rates were significantly lower in RS than LS: 8.7% vs. 16.1%, P=0.03 and 5.7% vs. 13%, P=0.02, respectively. **Conclusion**: In critically ill patients, a RS of red cell transfusion is as effective as a LS transfusion.
Therapeutic Platelet Transfusion Versus Routine Prophylactic Transfusion in Patients With Haematological Malignancies: An Open-Label, Multicentre, Randomised Study. Wandt et al. 2012	Lancet 2012;380:1309-16	**Title**: Therapeutic Platelet Transfusion Versus Routine Prophylactic Transfusion in Patients With Haematological Malignancies: An Open-Label, Multicentre, Randomised Study **Purpose**: To investigate the influence of a novel therapeutic platelet transfusion strategy on the number of transfusions and safety in patients with hypoproliferative thrombocytopenia. **Methods**: Patients (16-80 yr) undergoing chemotherapy for AML or autologous haemopoietic stem-cell transplantation were randomly assigned to receive either platelet transfusion when bleeding occurred (therapeutic strategy) or when morning platelet counts were $<10\times10^9$/L (prophylactic strategy; current standard of care). **Results**: In all patients, the therapeutic strategy reduced the mean number of platelet transfusions by 33.5% (95% CI 22.2-43.1; p<0.0001). Major haemorrhage was not increased in patients who had undergone autologous transplantation. Risk of non-fatal grade 4 bleeding was increased in patients with AML. **Conclusion**: The therapeutic strategy should be considered for patients following autologous stem-cell transplantation but not for patients with AML.
Transfusion Strategies for Acute Upper Gastrointestinal Bleeding. Villanueva et al. 2013	NEJM 2013;368:11-21	**Title**: Transfusion Strategies for Acute Upper Gastrointestinal Bleeding **Purpose**: To compare the efficacy and safety of a restrictive transfusion strategy with a liberal transfusion strategy in patients with acute upper GI bleeds. **Methods**: 921 patients with severe acute upper GI bleeding were assigned to either a restrictive strategy (transfusion when Hb <7 g/dL; target Hb = 7-9 g/dL) or a liberal strategy (transfusion when Hb <9 g/dL; target Hb = 9-11 g/dL). **Results**: Survival at 6 wk was higher in the restrictive-strategy group than in the liberal-strategy group (95% vs. 91%; hazard ratio, 0.55; 95% CI, 0.33-0.92; P=0.02). Further bleeding was more common in patients on restrictive-strategy than liberal-strategy (10% vs.16%; P=0.01); adverse events were also more common (40% vs. 48%; P=0.02). **Conclusion**: A restrictive transfusion strategy led to better outcomes than a liberal strategy in patients with acute upper GI bleeding.

Trial Name	Reference	Clinical Trial Details
Anemia		
CHOIR	NEJM 2006;355:2085-98	**Title**: Correction of Anemia with Epoetin α in Chronic Kidney Disease **Purpose**: To determine the optimal level of hemoglobin correction by recombinant human erythropoietin (epoetin α) in anemic CKD patients. **Methods**: 1432 patients with CKD were randomly assigned to receive a dose of epoetin alfa targeted to achieve a hemoglobin level of 13.5 g/dL or a dose targeted to achieve a level of 11.3 g/dL. **Results**: 125 composite events (death, MI, hospitalization for CHF, or stroke) were seen in the high-hemoglobin group, as compared with 97 events in the low-hemoglobin group (hazard ratio,1.34; 95% CI, 1.03-1.74; P=0.03). **Discussion**: In patients with anemia and CKD, targeting a lower Hb reduced incidence of death, MI, CHF-related hospitalization, and stroke.
Other		
CRASH-2	Health Technol Assess 2013;17(10):1-79	**Title**: The CRASH-2 Trial: A Randomised Controlled Trial and Economic Evaluation of the Effects of Tranexamic Acid on Death, Vascular Occlusive Events and Transfusion Requirement in Bleeding Trauma Patients **Purpose**: To assess how early administration of a short course of tranexamic acid (TXA) influences rates of death, vascular occlusive events and blood transfusions in trauma patients. **Methods**: 20211 adult trauma patients within 8 h of injury that had, or were at risk for, significant bleeding were randomized to receive TXA or matching placebo. **Results**: TXA significantly reduced all-cause mortality at 28 d (14.5% in TXA vs. 16.0% in placebo; p=0.0035). Death rates caused by bleeding were significantly reduced (4.9% vs. 5.7%; p=0.0077). The risk of death due to bleeding was increased by treatment given after 3 h (4.4% vs. 3.1%; p=0.004). **Conclusion**: The risk of death was safely reduced by early TXA in bleeding trauma patients. Beyond 3 h of injury, treatment is likely ineffective.

Acronyms

AFB	acid-fast bacilli
AIDS	acquired immunodeficiency syndrome
ANC	absolute neutrophil count
AOM	acute otitis media
ARDS	acute respiratory distress syndrome
ARV	anti-retroviral
ART	anti-retroviral therapy
BAL	bronchoalveolar lavage
BCG	Bacille Calmette-Guérin
BUN	blood urea nitrogen
CBC	complete blood count
CDC	Centers for Disease Control and Prevention
CFU	colony forming units
CLIA	ChemiLuminescent ImmunoAssay
CLL	chronic lymphocytic leukemia
CMIA	ChemiLuminescent Microparticle ImmunoAssay
CMV	cytomegalovirus
CNS	central nervous system
COVID-19	Coronavirus disease 2019
CSF	cerebrospinal fluid
CT	computed tomography
CXR	chest x-ray
DEET	N,N-Diethyl-meta-toluamide
DM	diabetes mellitus
DVT	deep vein thrombosis
EBV	Epstein-Barr virus
EHEC	enterohemorrhagic *E. coli*
EIA	enzyme immunoassay
EIEC	enteroinvasive *E. coli*
ETEC	enterotoxigenic *E. coli*
FDP	fibrinogen degradation products
FTA-ABS	fluorescent *Treponema* antibody-absorption
FUO	fever of unknown origin
GAS	group A *Streptococcus*
GBS	group B *Streptococcus*
GC	gonococcus
GI	gastrointestinal
GN	Gram-negative
GNB	Gram-negative bacilli
GP	Gram-positive
HAART	highly active anti-retroviral treatment
HAV	hepatitis A virus
HBc	HBV core antigen
HBeAg	HBV envelope antigen
HBsAg	HBV surface antigen
HBV	hepatitis B virus
HCC	hepatocellular carcinoma
HCV	hepatitis C virus
HDV	hepatitis D virus
HEV	hepatitis E virus
HHV	human herpes virus
Hib	*Haemophilus influenzae* b
HIV	human immunodeficiency virus
HPF	high power field
HPV	human papillomavirus
HRIg	human rabies immunoglobulin
HSV	herpes simplex virus
HTLV-1	Human T-lymphotropic virus 1
HUS	hemolytic uremic syndrome
IBD	inflammatory bowel disease
IDU	injecting drug use
IE	infective endocarditis
IFN	interferon
Ig	immunoglobulin
ILI	influenza-like illness
INH	isoniazid
INSTI	integrase strand transfer inhibitor
IVDU	intravenous drug use
IVIG	intravenous immunoglobulin
KOH	potassium hydroxide
KS	Kaposi's sarcoma
KSHV	Kaposi's sarcoma-associated herpes virus
LDL	low-density lipoprotein
LOC	level of consciousness
LP	lumbar puncture
MERS	Middle Eastern respiratory syndrome
MDR	multidrug resistance
MHA-TP	microhemagglutination assay *T. pallidum*
MMR	measles/mumps/rubella
MRSA	methicillin-resistant S. aureus
MSM	men who have sex with men
MSSA	methicillin-sensitive S. aureus
NRTI	nucleoside/nucleotide reverse transcriptase inhibitor
O&P	ova and parasites
PCP	*Pneumocystis pneumonia*
PCR	polymerase chain reaction
PI	protease inhibitor
PJP	*Pneumocystis jirovecii* pneumonia
PMN	polymorphonuclear leukocytes
PNS	peripheral nervous system
PPD	purified protein derivative
PWID	people who inject drugs
RA	rheumatoid arthritis
mRNA	messenger ribonucleic acid
RPR	rapid plasma reagin
RSV	respiratory syncytial virus
RTI	respiratory tract infection
RT-PCR	reverse transcription-PCR
SARS	severe acute respiratory syndrome
SCID	severe combined immunodeficiency
SIADH	syndrome of inappropriate antidiuretic hormone secretion
Sn	sensitivity
Sp	specificity
spp.	species
SRI	severe respiratory illness
STEC	Shiga toxin-producing *E. coli*
STI	sexually transmitted infection
TB	*Mycoplasma tuberculosis*
TG	triglycerides
TIg	tetanus immune globulin
TMP/SMX	trimethoprim-sulfamethoxazole
TNF	tumour necrosis factor
TORCH	toxoplasmosis, other, rubella, cytomegalovirus, HSV
TPI	*T. pallidum* immobilization test
TPPA	*T. pallidum* particle agglutination assay
TSS	toxic shock syndrome
TST	tuberculin skin test
URTI	upper respiratory tract infection
U/S	ultrasound
UTI	urinary tract infection
VDRL	venereal disease research laboratory
VRE	vancomycin-resistant Enterococcus
VZV	varicella-zoster virus

Principles of Microbiology

Bacteriology

Bacteria Basics

- bacteria are prokaryotic cells that divide asexually by binary fission
- Gram stain divides most bacteria into two groups based on their cell wall
  - GP: thick, rigid layer of peptidoglycan
  - GN: thin peptidoglycan layer + outer membrane composed of lipoproteins and lipopolysaccharides
  - clinical significance: Gram stain results are used to guide tailored empiric treatment prior to availability of culture and susceptibility testing results
- acid-fast bacilli (AFB): high mycolic acid content in cell wall, called "acid fast" because they resist stain decolourization despite acid-alcohol washes (e.g. *Mycobacteria*)
- partially AFB: bacteria with moderate mycolic acid content that will decolourize with the acid alcohol used in AFB stains but are considered partially acid-fast positive based on a modified acid-fast stain with a weaker acid during the washout phase (e.g. *Nocardia*)
  - note that *Nocardia* will be acid-fast stain negative and modified acid-fast stain positive, while *Mycobacteria* will be positive on both acid-fast and modified acid-fast stains
- "atypical" bacteria: not seen on Gram stain and difficult to culture
  - obligate intracellular bacteria: e.g. *Chlamydia*
  - bacteria lacking a cell wall: e.g. *Mycoplasma*
  - spirochetes: e.g. *Treponema pallidum*
- O_2 can be either vital or detrimental to growth
  - obligate aerobes: require O_2
  - obligate anaerobes: require environment without O_2
  - facultative anaerobes: can survive in environments with or without O_2

Mechanisms of Bacterial Disease

1. adherence to and colonization of skin or mucous membranes
   - fimbriae (pili): microfilaments extending through the cell wall attach to epithelial cells (e.g. *E. coli* in the urinary tract)
2. invasion or crossing epithelial barriers
3. evasion of host defense system through:
   - inhibition of phagocytic uptake via polysaccharide capsule (e.g. *S. pneumoniae, N. meningitidis, H. influenzae*)
   - presence of surface proteins (e.g. *Staphylococcus, Streptococcus*)
4. toxin production
   - exotoxins are secreted by living pathogenic bacteria and cause disease even if the bacteria are not present (e.g. *Clostridium*)
   - endotoxins are structural components of GN bacterial cell walls and may be shed by live cells or released during cell lysis
5. intracellular growth
   - obligate intracellular: *Rickettsia, Chlamydia*
   - facultative intracellular: *Salmonella, Neisseria, Brucella, Mycobacteria, Listeria, Legionella*
6. biofilm
   - an extracellular polysaccharide network forming mesh around the bacteria (e.g. *S. epidermidis*) which can coat prosthetic devices such as IV catheters

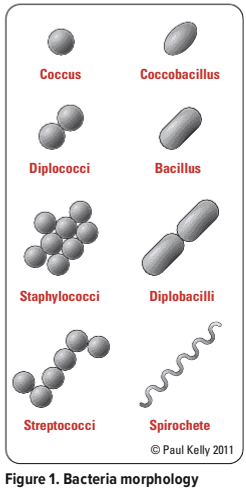

Figure 1. Bacteria morphology

Table 1. Common Bacteria

	GP Bacteria		GN Bacteria		Not Seen on Gram Stain	
	Cocci (round)	**Bacilli (rod-like)**	**Diplococci**	**Bacilli (rod-like)**	**Acid-Fast**	**Others**
Aerobes	*Staphylococcus* *S. aureus* *S. saprophyticus* *S. epidermidis* *S. lugdunensis* *Streptococcus* *S. pneumoniae* *S. pyogenes* (GAS) *S. agalactiae* (GBS) *S. anginosus group* *Enterococcus* *E. faecalis*	Bacillus *B. anthracis* *Listeria* *Nocardia* (modified acid-fast positive)	*Neisseria* *N. meningitidis* *N. gonorrhoeae* *Moraxella* *M. catarrhalis*	*Enterobacterales* *E. coli* *Klebsiella* *Salmonella* *Shigella* *Yersinia* *Campylobacter* *Legionella* *Pseudomonas* *Haemophilus* *H. influenzae*	*Mycobacteria* *M. tuberculosis* *M. leprae* *M. avium* complex	Obligate intracellular *Rickettsiae* *Chlamydia* *C. trachomatis* *C. pneumoniae* No cell wall *Mycoplasma* Spirochete (spiral) *Treponema pallidum*
Anaerobes	*Peptostreptococcus*	*Clostridioides difficile* *Clostridium* *C. tetani* *C. botulinum* *C. perfringens* *Cutibacterium (Propionibacterium) acnes*		*Bacteroides* *B. fragilis*		

Table 2. Commensal Flora

Site	Organisms
Skin	Coagulase-negative staphylococci, *Corynebacterium, C. acnes, Bacillus, S. aureus*
Oropharynx	Viridans group streptococci, *Haemophilus, Neisseria*, anaerobes (*Peptostreptococcus, Bacteroides, Veillonella, Fusobacterium, Actinomyces, Prevotella*)
Small Bowel	*E. coli*, anaerobes (low numbers)
Colon	*E. coli, Klebsiella, Enterobacter, Enterococcus*, anaerobes (*Bacteroides, Peptostreptococcus, Clostridium*)
Vagina	*Lactobacillus acidophilus*, viridans group streptococci, coagulase-negative staphylococci, facultative anaerobes

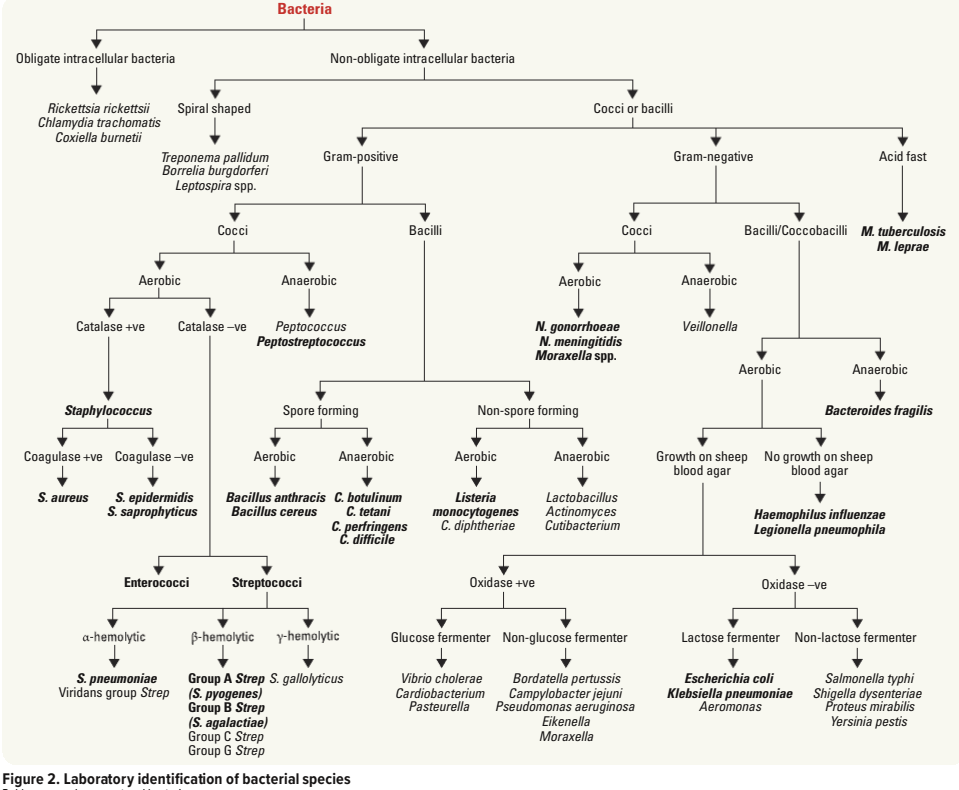

Figure 2. Laboratory identification of bacterial species
Bold = commonly encountered bacteria

Virology

Viral Basics

- viruses are infectious particles consisting of RNA or DNA covered by a protein coat
  - infect cells and use host metabolic machinery to replicate
  - nucleic acid can be double stranded (ds) or single stranded (ss)
  - nucleic acid can be positive sense (+) or negative sense (-)
  - can be enveloped or naked
- virions are mature virus particles that can be released into the extracellular environment
- host susceptibility is governed by the host cell and virus surface proteins (viral tropism) and cellular immunity

Viral Disease Patterns

1. acute infections (e.g. adenovirus)
   - host cells are lysed in the process of virion release
   - some produce acute infections with late sequelae (e.g. measles virus-induced subacute sclerosing panencephalitis)
2. chronic infections (>6 mo) (e.g. HBV, HIV)
   - host cell machinery is used to produce and chronically release virions
3. latent infections
   - viral genome remains latent in host cell nucleus
   - can reactivate (e.g. HSV, VZV)

Table 3. Common Viruses

Nucleic Acid	Enveloped	Virus Family	Major Viruses	Medical Importance
dsDNA	No	Adenoviridae	Adenovirus	URTI Conjunctivitis Gastroenteritis
	No	Papillomaviridae	HPV1,4 HPV6,11 HPV16,18, etc.	Plantar warts Genital warts Cervical/anal dysplasia and cancer
	Yes	Herpesviridae	HHV1=HSV1 HHV2=HSV2 HHV3=VZV HHV4=EBV HHV5=CMV HHV6* HHV8=KSHV	Oral, ocular, and genital herpes; encephalitis Genital, oral, and ocular herpes; encephalitis Chicken pox, shingles Mononucleosis, viral hepatitis Retinitis, pneumonitis, hepatitis, encephalitis Roseola Kaposi's sarcoma, multicentric Castleman's disease, body cavity lymphoma
	No	Polyomaviridae	JC virus	Progressive multifocal leukoencephalopathy
	Yes	Hepadnaviridae	Hepatitis B	Hepatitis
	Yes	Poxviridae	Monkeypox Smallpox	Monkeypox Smallpox
ssDNA	No	Parvoviridae	Parvovirus B19	Erythema infectiosum (Fifth disease)
(+) ssRNA	No	Caliciviridae	Noroviruses Hepatitis E	Gastroenteritis Acute hepatitis
	No	Picornaviridae	Poliovirus Echovirus Rhinovirus Coxsackie virus Hepatitis A	Poliomyelitis URTIs, viral meningitis URTIs Hand-foot-and-mouth, viral meningitis, myocarditis Acute hepatitis
	Yes	Coronaviridae	Coronavirus	URTIs, SARS, MERS, COVID-19
	Yes	Flaviviridae	Yellow fever Dengue fever Hepatitis C West Nile Zika	Yellow fever Dengue fever Hepatitis Encephalitis, flaccid paralysis Zika virus disease
	Yes	Togaviridae	Rubella Chikungunya	Rubella (German measles) Chikungunya
(+) ssRNA-RT	Yes	Retroviridae	HIV HTLV-1	AIDS T-cell leukemia and lymphoma
(-) ssRNA	Yes	Arenaviridae	Lassa	Lassa fever
	Yes	Filoviridae	Ebola, Marburg	Hemorrhagic fever
	Yes	Orthomyxoviridae	Influenza A, B, C	Influenza
	Yes	Paramyxoviridae	Measles Mumps Parainfluenza RSV	Measles Mumps URTIs, croup, bronchiolitis Bronchiolitis, pneumonia
	Yes	Rhabdoviridae	Rabies	Rabies
dsRNA	No	Reoviridae	Rotavirus	Gastroenteritis

Note: ___viridae = family, ___virus = genus, # = species (e.g. Retroviridae HIV-2)
*Roseolovirus, Herpes lymphotropic virus

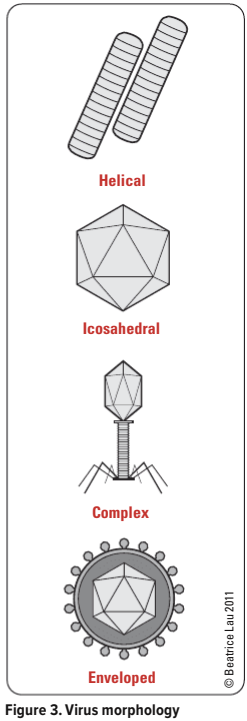

Figure 3. Virus morphology

DNA Viruses: Families

HHAPPPPy
Hepadnaviridae
Herpesviridae
Adenoviridae
Papillomaviridae
Parvoviridae
Polyomaviridae
Poxviridae

Mycology

Fungal Basics

- fungi are eukaryotic organisms, they can have the following morphologies
  1. yeast (unicellular)
  2. moulds, i.e. filamentous fungi (multicellular with hyphae)
  3. dimorphic fungi (found as mould at room temperature but grow as yeast-like forms at body temperature)

Table 4. Membrane and Cell Wall Compositions

	Membrane Sterol	Cell Wall
Bacteria	–	Peptidoglycan
Human Cell	Cholesterol	–
Fungi	Ergosterol	Chitin (complex glycopolysaccharide)

Mechanisms of Fungal Disease

- primary fungal infection by:
  - overgrowth of normal flora (e.g. *Candida* spp.)
  - inhalation of fungal spores
  - traumatic inoculation into skin
- toxins produced by fungi (e.g. ingestion of aflatoxins)
- allergic reactions to fungi (e.g. bronchopulmonary aspergillosis)

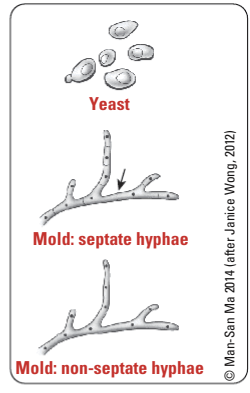

Figure 4. Common fungus morphology

Parasitology

Parasite Basics

- parasite: an organism that lives in or on another organism (host) and damages the host in the process
- parasites with complex life cycles require more than one host to reproduce
  - reservoir host: maintains a parasite and may be the source for human infection
  - intermediate host: maintains the asexual stage of a parasite or allows development of the parasite to proceed through the larval stages
  - definitive host: allows the parasite to develop to the adult stage where reproduction occurs
- 2 major groups of parasites: protozoa and helminths
- see *Table 25, ID33* and *Table 26, ID39* for examples of clinically important parasites

Table 5. Differences Between Protozoa and Helminths

Protozoa	Helminths
Unicellular	Multicellular
Motile trophozoite, inactive cyst	Adult → egg → larva
Multiplication	No multiplication in human host
Eosinophilia unusual	Eosinophilia (proportional to extent of tissue invasion)*
Indefinite life span	Definite life span

*Adult *Ascaris* (roundworm) does not cause eosinophilia; migratory larval phases of *Ascaris*, however, cause high-grade eosinophilia

Characteristics of Parasitic Disease

- symptoms are usually proportional to parasite burden
- tissue damage is due to the parasite and host immune response
- chronic infections may occur with or without overt disease
- immunocompromised hosts are more susceptible to manifestations of infection, reactivation of latent infections, and more severe disease
- eosinophilia may suggest a parasitic worm infection

Mechanisms of Parasitic Disease

1. mechanical obstruction (e.g. ascariasis, clonorchiasis)
2. competition with host for resources (e.g. anemia in hookworm disease, vitamin B_{12} deficiency in diphyllobothriasis)
3. cytotoxicity leading to abscesses and ulcers (e.g. amoebiasis, leishmaniasis)
4. inflammatory
   - acute hypersensitivity (e.g. pneumonitis in Loeffler's syndrome)
   - delayed hypersensitivity (e.g. egg granulomas in schistosomiasis)
   - cytokine-mediated (e.g. systemic illness of malaria, disseminated strongyloidiasis)
5. immune-mediated injury
   - autoimmune (e.g. myocarditis of Chagas disease, tissue destruction of mucocutaneous leishmaniasis)
   - immune complex (e.g. nephritis of malaria, schistosomiasis)

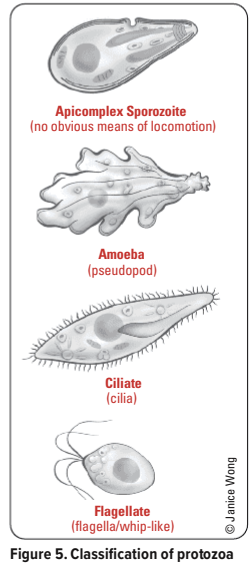

Figure 5. Classification of protozoa based on movement

Parasite sampling may need to be repeated on several occasions before infection can be ruled out

Transmission of Infectious Diseases

Table 6. Mechanism of Transmission

Mechanism	Mode of Transmission	Examples	Preventative Measure
Contact	Direct physical contact, or indirect contact with a fomite	Skin-to-skin (MRSA) Sexual (*N. gonorrhoeae, C. trachomatis*, HSV, HIV) Blood-borne (HIV, HBV, HCV)	For patients in healthcare facilities: Contact precautions Barrier precautions Safe needlestick/sharp practices
Droplet/Contact	Respiratory droplets (>5 µm) can be projected short distances (≤2 m) and deposit on mucosal surfaces of the recipient (e.g. by coughing, sneezing, or talking); transmission can also occur by direct physical contact of respiratory fluids or indirect contact with a fomite contaminated with respiratory fluids	Influenza, mumps, *N. meningitidis, Bordetella pertussis*	For patients in healthcare facilities: Contact/droplet precautions
Airborne	Airborne droplet nuclei (<5 µm) remain infectious over time and distance	*M. tuberculosis*, disseminated VZV, measles	For patients in healthcare facilities: Airborne precautions
Food/ Waterborne	Ingestion of contaminated food or water	*V. cholerae, Salmonella*, HAV, HEV	Prophylactic vaccinations where available Ensure clean food/water supply For patients in healthcare facilities: Contact precautions used for admitted patients with fecal incontinence when stool is unable to be contained in diapers
Zoonotic/Vector-borne	Disease transmission from animals to humans either directly or via an insect vector, or disease transmission from human to human via an insect vector	Direct animal transmission (rabies, Q fever) Arthropod mediated transmission (malaria, Lyme disease, West Nile virus)	Prophylactic medications, vaccinations Prophylactic medications, vaccinations Protective clothing, insect repellent, mosquito nets, tick inspection
Vertical	Spread of disease from parent to offspring	Congenital syndromes (TORCH infections) Perinatal (HIV, HBV, GBS)	Prenatal screening Prophylactic treatment

Nosocomial Infections

- **definition**: infections acquired >48 h after admission to a healthcare facility OR within 30 d from discharge
- **risk factors**: prolonged hospital stay, antibiotic use, surgery, hemodialysis, intensive care, colonization with a resistant organism, and immunodeficiency
  - patients with nosocomial infections have higher mortality, longer hospital stays, and higher healthcare costs
- hand hygiene is an essential precaution

Table 7. Common Nosocomial Infectious Agents

Bacteria	Characteristics	Manifestation	Investigations	Management
MRSA	GP cocci	Skin and soft tissue infection Bacteremia Pneumonia Endocarditis Osteomyelitis	Admission screening culture from nares and peri-anal region identifies colonization Culture of infection site CXR	Contact precautions For infection: vancomycin, daptomycin, or linezolid To decolonize: chlorhexidine 2% wash once daily (+ rifampin + (doxycycline or TMP/SMX) + mupirocin cream BID to nares) x 7 d
VRE	Majority are *E. faecium* Resistant if minimum inhibitory concentration of vancomycin is ≥32 µg/mL	Rarely causes disease in healthy people UTI Bacteremia Endocarditis Meningitis	Rectal or perirectal swab OR stool culture for colonization Culture of infected site	Contact precautions* Ampicillin if susceptible Otherwise, linezolid, tigecycline, or daptomycin depending on site of infection No effective decolonization methods identified
***Clostridioides difficile* (*C. difficile*)**	Releases exotoxins A and B Hypervirulent strain (NAP1/B1/027) has been responsible for increase in incidence and severity	Fever, nausea, abdominal pain Watery diarrhea Pseudomembranous colitis Severe: toxic megacolon Risk of bowel perforation Associated with antibiotic use Leukocytosis	Stool PCR for toxin A and B genes Stool immunoassay for toxins A and B (less sensitive than PCR) Abdominal x-ray (may see colonic dilatation) Sigmoidoscopy for pseudomembranes; avoid if known colonic dilatation	Contact precautions Stop culprit antibiotic therapy (primarily fluoroquinolones and clindamycin) Supportive therapy (IV fluids) Empiric treatment with either vancomycin or fidaxomicin If access to empiric treatment is limited, then metronidazole may be used For fulminant *C. difficile* infection (previously called severe), oral vancomycin is used. IV metronidazole added to regimen if ileus present
Extended Spectrum β-lactam Producers (e.g. ESBL producing *E. coli, K. pneumoniae*)	Resistant to most β-lactam antibiotics except carbapenems e.g. penicillins, aztreonam**, and cephalosporins	UTI Pulmonary infection Bacteremia Liver abscess in susceptible patients Meningitis	Blood, sputum, urine, or aspirated body fluid culture Imaging at infection site (CXR, CT, U/S)	Contact precautions* Carbapenems or non-β-lactam antibiotics can be used for empiric therapy
Carbapenemase-producing Enterobacterales (CPE)	Resistant to β-lactam antibiotics including carbapenems	UTI Pulmonary infection Bacteremia Liver abscess in susceptible patients Meningitis	Blood, sputum, urine, or aspirated body fluid culture Imaging at infection site (CXR, CT, U/S)	Contact precautions Colistin, tigecycline can be used varying on susceptibility Cefiderocol, ceftazidime-avibactam, or plazomicin are other options available through the Special Access Program

*The use of contact precautions for VRE and ESBL varies depending on institutional policies. **Not available in Canada

Respiratory Infections

Pneumonia

- see Pediatrics, P68

Definition

- infection of the lung parenchyma

Etiology and Risk Factors

- impaired lung defenses
  - poor cough/gag reflex (e.g. illness, drug-induced)
  - impaired mucociliary transport (e.g. smoking, cystic fibrosis)
  - immunosuppression (e.g. steroids, chemotherapy, AIDS/HIV, DM, transplant, cancer)
- increased risk of aspiration
  - impaired swallowing mechanism (e.g. impaired consciousness, neurologic illness causing dysphagia)
- mechanical obstruction
- no organism identified in 75% of hospitalized cases, and >90% of ambulatory cases

Table 8. Common Organisms in Pneumonia

Community-Acquired	Nosocomial	Aspiration	Immunocompromised Patients	Alcohol Use Disorder
Typical Bacteria *Streptococcus pneumoniae* *Moraxella catarrhalis* *Haemophilus influenzae* *Staphylococcus aureus* GAS Atypical Bacteria *Mycoplasma pneumoniae* *Chlamydia pneumoniae* *Legionella pneumophila* Viral *Influenza virus* *Adenovirus* *SARS-CoV-2*	Enteric GNB (e.g. *E. coli*) *Pseudomonas aeruginosa* *S. aureus* (including MRSA)	Oral anaerobes (e.g. *Bacteroides*) Enteric GNB *S. aureus* Gastric contents (chemical pneumonitis)	*Pneumocystis jirovecii* Fungi (e.g. *Cryptococcus*) *Nocardia* CMV HSV TB	*Klebsiella* Enteric GNB *S. aureus* Oral anaerobes (aspiration) TB

*See Pediatrics, P87, Table 45, *Common Causes and Treatment of Community-Acquired Pneumonia*

Clinical Features

- cough (± sputum), fever, pleuritic chest pain, dyspnea, tachypnea, and tachycardia
- elderly often present atypically; altered LOC is sometimes the only sign
- evidence of consolidation (dullness to percussion, bronchial breath sounds, and crackles)
- features of parapneumonic effusion (decreased air entry, dullness to percussion)
- complications: ARDS, lung abscess, parapneumonic effusion/empyema, and pleuritis ± hemorrhage

Investigations

- pulse oximetry to assess severity of respiratory distress
- CBC and differential, electrolytes, urea, creatinine, arterial blood gas (ABG) (if respiratory distress)
- sputum Gram stain/C&S, blood C&S, ± viral detection (influenza testing), ± serology, and ± pleural fluid C&S (if effusion >5 cm or respiratory distress)
- CXR ± CT chest shows distribution (lobar consolidation or interstitial pattern), extent of infiltrate ± cavitation
- bronchoscopy ± washings for: (1) severely ill patients refractory to treatment and (2) immunocompromised patients

Treatment

- airway/breathing/circulation, O_2, IV fluids, consider salbutamol (nebulized or metered-dose inhaler)
- determine prognosis and need for hospitalization and antibiotics

Criteria for Hospitalization

- along with clinical judgment, validated clinical prediction rules for prognosis can be used to determine the need for hospitalizations in adults diagnosed with community-acquired pneumonia (e.g. the CURB-65 Score or Pneumonia Severity Index (PSI))

Table 9. CURB-65 Score – Pneumonia Clinical Prediction Tool

Component*	Measurement(s)	Points	Total Score	Mortality	Disposition
Confusion	Altered mental status	1	0-1	<5%	Can treat as outpatient
Urea/BUN	Urea >7 mmol/L or BUN >20 mg/dL	1	2-3	5-15%	Consider hospitalization
Respiratory Rate	>30 breaths/min	1	4-5	15-30%	Consider ICU
Blood Pressure	sBP <90 mmHg or dBP <60 mmHg	1			
Age	65 or older	1			

*A CRB-65 score may also be applied in community acquired pneumonia. Its criteria depends on clinical assessment alone

When Klebsiella causes pneumonia: see red currant jelly sputum

3 As of *Klebsiella*
Aspiration pneumonia
Alcohol use disorder and patients with diabetes
Abscess in lungs

Aspiration pneumonias more commonly manifest as infiltrates in the right middle or lower lobes due to the larger calibre and more vertical orientation of the right bronchus

Healthcare-Associated Infections and Antimicrobial Resistance in Canadian Acute Care Hospitals
Can Commun Dis Rep 2020;46:99-112
Purpose: To describe the trends of healthcare-associated infections (HAIs) and antimicrobial resistance (AMR) from 2014 to 2018 using surveillance data from the Canadian Nosocomial Infection Surveillance Program.
Methods: Data were collected from 70 Canadian sentinel hospitals regarding Clostridioides difficile infection (CDI), MRSA bloodstream infections, VRE bloodstream infections, and carbapenemase-producing Enterobacteriaceae.
Results: Rates per 10,000 patient-days increased for MRSA (59%; 0.66-1.05, P=0.023) and VRE bloodstream infections (143%; 0.14-0.34, P=0.023). However, CDI rates decreased by 12.5% (from 6.16-5.39, P=0.042). Carbapenemase-producing Enterobacteriaceae colonization increased by 375% (0.04-0.19; P=0.014) but infection rates remained low and stable.
Conclusion: Standardized surveillance data from acute care hospitals in addition to antimicrobial stewardship will be crucial for the ongoing prevention of HAIs and AMR in Canada.

For a report on nosocomial infections in the US, please refer to: NEJM 2014;370:1198-208. Consult your local hospital statistics for the most applicable information for your workplace.

Diagnosis of Ventilator-Associated Pneumonia in Critically Ill Adult Patients: A Systematic Review and Meta-Analysis
Intensive Care Med 2020;46:1170-79
Purpose: To identify and compare the accuracy of the following measures for diagnosing VAP: physical examination, chest radiography, endotracheal aspirate (ETA), bronchoscopic sampling cultures (protected specimen brush (PSB) and bronchoalveolar lavage (BAL)), and CPIS >6.
Study Selection: Eligible observational studies and RCTs included ≥90% patients over 16 y/o with measures conducted in the ICU, including patients with minimum 48 h of invasive mechanical ventilation.
Results: The collective sensitivity and specificity of VAP physical examination findings were poor: fever (66.4% and 53.9%, respectively) and purulent secretions (77.0%, 39.0%); any infiltrate on chest radiography (88.9%, 26.1%); ETA (75.7%, 67.9%). Among bronchoscopic sampling methods, PSB (61.4%, 76.5%); BAL (71.1%, 79.6%). CPIS>6 (73.8%, 66.4%).
Conclusion: VAP misdiagnosis and potentially unnecessary antimicrobial use may result from reliance on classical clinical measures used in isolation.

Table 10. Pneumonia Severity Index – Clinical Prediction Rule for Prognosis

Risk Factor	Points	Total Score	Risk Class	Mortality	Recommendation
Demographics		<51	I	0.1%	Consider outpatient
Men	Age (yr)				
Women	Age (yr) – 10				
Nursing home resident	+10				
Coexisting Illness		51-70	II	0.6%	Consider outpatient
Neoplastic disease	+30				
Liver disease	+20				
Congestive heart failure	+10				
Cerebrovascular disease	+10				
Renal disease	+10				
Physical Exam		71-90	III	0.9-2.8%	Consider outpatient
Altered mental status	+20				
Respiratory rate ≥30 breaths/min	+20				
sBP <90 mmHg	+20				
T <35°C or ≥40°C	+15				
HR ≥125 bpm	+10				
Investigations		91-130	IV	8.2-9.3%	Hospitalize
Arterial pH <7.35	+30				
BUN ≥30 mg/dL	+20				
Sodium <130 mmol/L	+20	>130	V	27.0-29.2%	Hospitalize
Glucose ≥250 mg/dL	+10				
Hematocrit <30%	+10				
Partial pressure of arterial O_2 <60 mmHg	+10				
Pleural effusion	+10

Table 11. IDSA/ATS Community-Acquired Pneumonia Treatment Guidelines 2019

Setting	Circumstances	Treatment
Outpatient	No comorbidities or risk factors for MRSA or *P. aeruginosa* [1]	Amoxicillin OR Doxycycline OR Macrolide (local pneumococcal resistance <25%)[2]
	Comorbidities [3]	Amoxicillin/clavulanate or cephalosporin[4] AND Macrolide[2] or doxycycline OR Respiratory fluoroquinolone[5]
Inpatient	Nonsevere inpatient pneumonia[6] and no risk factors for MRSA or *P. aeruginosa*[1]	β-lactam[7] ± macrolide [2] OR respiratory fluoroquinolone[5]
	Severe inpatient pneumonia[6] and no risk factors for MRSA or *P. aeruginosa*[1]	β-lactam[7]+ macrolide [2]OR β-lactam[7]+ fluoroquinolone [5]

Given different regional resistance patterns, therapy should be based on local epidemiology and site-specific recommendations
Refers to empiric treatment to be started. Appropriate antibiotic therapy should be tailored if pathogen is identified
1. Previous respiratory isolation of MRSA or *P. aeruginosa* or recent hospitalization AND parenteral antibiotic use in last 3 mo ± locally validated risk factors
2. **Macrolide:** use azithromycin or clarithromycin
3. **Comorbidities:** chronic heart, lung, liver, or renal disease, DM, alcohol use disorder, malignancy, asplenia
4. **Cephalosporin:** cefpodoxime or cefuroxime
5. **Respiratory fluoroquinolone:** moxifloxacin, levofloxacin
6. Severe = 1 major criterion or ≥3 minor criteria. Minor criteria: respiratory rate ≥30 breaths/min, PaO_2/FiO_2 ratio ≤250, multilobar infiltrates, confusion/disorientation, BUN ≥20 mg/dL, WBC <4000/μL due to infection, Plt <100000/μL, T <36°C, hypotension with aggressive fluid resuscitation. Major criteria: septic shock with vasopressors, respiratory failure with mechanical ventilation
7. **β-lactam:** ampicillin sulbactam*, cefotaxime, ceftriaxone, ceftaroline*
IDSA: Infectious Diseases Society of America
ATS: American Thoracic Society
*Available in Canada through the Special Access Program

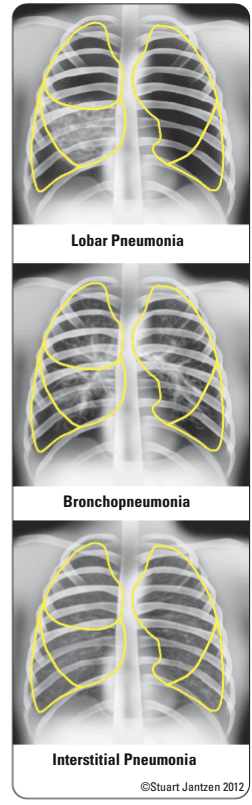

Figure 6. Lobar, broncho-, and interstitial pneumonia

Diagnosis and Treatment of Adults with Community-Acquired Pneumonia: An Official Clinical Practice Guideline of the American Thoracic Society and Infectious Diseases Society of America
Am J Respir Crit Care Med 2019;200:e45-e67

- The Pneumonia Severity Index is preferred over the CURB-65 tool for determining inpatient vs. outpatient treatment.
- Test for influenza with a rapid influenza molecular assay when it is circulating in the community.
- Obtaining blood C&S or sputum Gram stain/C&S routinely in adults with CAP managed in the outpatient setting is not recommended.
- Obtaining pre-treatment blood C&S and sputum Gram stain/C&S is recommended in adults with CAP managed in the hospital setting who (1) are classified as severe CAP or (2) are being empirically treated for MRSA or P. aeruginosa or (3) were previously infected with MRSA or P. aeruginosa or (4) were hospitalized and received parenteral antibiotics in the last 90 d.

Table 12. IDSA/ATS Hospital-Acquired (HAP) and Ventilator-Associated (VAP) Pneumonia Clinical Practice Guidelines 2016

Setting	Treatment
Clinically suspected **HAP** (non-VAP) with no increase in likelihood of MRSA and not at high-risk of mortality	**One of:** piperacillin-tazobactam OR cefepime OR levofloxacin OR imipenem OR meropenem
Clinically suspected **HAP** (non-VAP) with increasing likelihood of MRSA and not at high-risk of mortality	**One of:** piperacillin-tazobactam OR cefepime or ceftazidime OR levofloxacin or ciprofloxacin OR imipenem or meropenem OR aztreonam* **PLUS one of:** vancomycin or linezolid for MRSA coverage
Clinically suspected **HAP** (non-VAP) with high-risk of mortality or recipient of IV antibiotics in last 90 d	**Two of the following (avoid 2 β-lactams):** piperacillin-tazobactam OR cefepime or ceftazidime OR levofloxacin or ciprofloxacin OR imipenem or meropenem OR aztreonam* OR amikacin or gentamicin or tobramycin **PLUS either MRSA or MSSA coverage:** **MRSA**: vancomycin or linezolid OR **MSSA**: piperacillin-tazobactam, cefepime, levofloxacin, imipenem, meropenem
Clinically suspected **VAP** in units where empiric **MRSA** coverage and double antipseudomonal/**GN** coverage are appropriate	**One of:** β-lactam/β-lactamase inhibitor (piperacillin/tazobactam) OR antipseudomonal cephalosporin (cefepime or ceftazidime) OR antipseudomonal carbapenem (imipenem or meropenem) OR monobactam (aztreonam*) **PLUS one of:** antipseudomonal fluoroquinolone (ciprofloxacin or levofloxacin) OR aminoglycoside (amikacin, gentamicin, or tobramycin) OR polymyxins (colistin or polymyxin B) **PLUS one of:** vancomycin or linezolid for MRSA coverage

Refers to empiric treatment to be started. Appropriate antibiotic therapy should be tailored if pathogen is identified
***Available in Canada through the Special Access Program**
Risk factors for mortality include need for ventilatory support due to pneumonia and septic shock
Risk factors for MDR VAP: prior IV antibiotic use within 90 d, septic shock at time of VAP, ARDS preceding VAP, 5+ d of hospitalization prior to VAP onset, acute renal replacement therapy prior to VAP onset
Risk factors for MDR HAP, MRSA VAP/HAP, or MDR *Pseudomonas* VAP/HAP: Prior IV antibiotic use within 90 d
Note: Indications for MRSA coverage includes IV antibiotic treatment during the prior 90 d and treatment in a unit where prevalence of MRSA of *S. aureus* isolates is not known or is >20%
Note: These guidelines may be less applicable in Canada given lower rates of antibiotic resistance among common nosocomial pathogens

Prevention

- Public Health Agency of Canada recommends the following:
  - vaccine for influenza A and B annually for all ages ≥6 mo
  - pneumococcal polysaccharide vaccine (Pneumovax®) for all adults ≥65 yr and in younger patients ≥24 mo at high-risk for invasive pneumococcal disease (e.g. functional or anatomic asplenia, congenital or acquired immunodeficiency)
  - pneumococcal conjugate vaccine (Prevnar-13®) for children and adolescents ages 5-17 yr at high risk for invasive pneumococcal disease and who have not previously received Prevnar-13® (CDC recommends giving Prevnar-13® to all adults at high-risk for invasive pneumococcal disease)
  - mRNA COVID-19 vaccine (Moderna (Spikevax®) or Pfizer-BioNTech (Comirnaty®)) for all ages ≥6 mo who do not have contraindications, with boosters as per public health guidance

Influenza

Definitions and Etiology

- influenza viruses A and B
- influenza A further divided into subtypes based on envelope glycoproteins
  - hemagglutinin (H) and neuraminidase (N)
- seasonal (epidemic) influenza
  - main circulating influenza viruses: influenza A (H1N1), influenza A (H3N2), and influenza B
  - associated with antigenic drift (gradual, minor changes due to random point mutations)
  - may create a new viral subtype resulting in a seasonal epidemic (disease prevalence is greater than expected)
  - outbreaks occur mainly during winter months (late December to early March)
- pandemic influenza
  - associated with antigenic shift: abrupt, major changes due to mixing of two different viral strains from different hosts
  - may create a new viral strain resulting in a pandemic outbreak (worldwide)
  - antigenic shift occurs only in type A
- transmission: droplet, possibly airborne

Does this Patient have Community-Acquired Pneumonia?
Diagnosing Pneumonia by History and Physical Examination
JAMA 1997;278:1440-1445
Study: Systematic review of articles assessing the sensitivity and specificity of clinical exam maneuvers for the diagnosis of adult community-acquired pneumonia.
Results: The presence of fever or immunosuppression had a positive likelihood ratio (+LR) of 2, while a history of dementia had a +LR of 3; however, these traits are not confirmatory. The presence of an abnormality in any vital sign, including tachycardia, tachypnea, or fever had a +LR ranging from 2-4, which was not significantly affected by different cut-points. The absence of vital sign abnormality had a –LR ranging from 0.5-0.8. The combination of respiratory rate <30 breaths/min, heart rate <100 bpm, and temperature <37.8°C had a –LR of 0.18. Findings on chest exam raised the likelihood of diagnosis but were uncommonly seen in studies (e.g. presence of asymmetric respirations essentially confirmed the diagnosis but was only present in 4% of patients). In patients with a clinical diagnosis but normal radiograph, only ~10% will develop radiographic findings in 72 h.
Conclusions: Evidence suggests no single item on clinical history or physical exam is sufficient to rule in or out pneumonia without CXR. Vital sign abnormalities were correlated with a diagnosis of pneumonia. Findings on chest exam significantly raised the likelihood of pneumonia but were uncommonly seen in studies.

Beware! Do Not Confuse *H. influenzae* with Influenza Virus
H. influenzae: a bacterium (Types A, B, C, D, E, and F refer to capsule)
Influenza: a virus (Types A and B refer to strain)

Vaccines for Preventing Influenza in Healthy Adults
Cochrane DB Syst Rev 2018;CD001269
Study: 52 RCTs and quasi-RCTs evaluating influenza vaccines compared to placebo or no intervention in healthy individuals 16-65 yr. Observational comparative studies were not included.
Results: Inactivated influenza vaccines reduce influenza in healthy adults from 2.3% to 0.9% and reduce influenza-like illness (ILI) from 21.5% to 18.1%. The preventative effect of vaccination is small, with 71 healthy adults needing to be vaccinated to prevent one from experiencing influenza, and 29 needing to be vaccinated to prevent one from experiencing ILI. Vaccination leads to a small reduction in the risk of hospitalization from 14.7% to 14.1%, and a small reduction in days off work. Effectiveness of the influenza vaccine is less in mothers and newborns compared to the general population.
Conclusions: Influenza vaccines have a very modest effect in reducing influenza, associated symptoms, hospitalization, and days off work in healthy adults.

Table 13. Difference Between Influenza Strains

	Influenza A	Influenza B
Host(s)	Humans, birds, mammals	Humans only
Antigenic Drift	Yes, new strains	Yes, new strains
Antigenic Shift	Yes, new subtypes	No
Epidemics	Yes	Yes
Pandemics	Yes	No

Acute Myocardial Infarction after Laboratory-Confirmed Influenza Infection
NEJM 2018;378:345-353
Purpose: To investigate the association between laboratory-confirmed influenza infection and acute MI.
Methods: Self-controlled case-series. Risk interval defined as first 7 d after respiratory specimen collection and control interval as 1 yr before and 1 yr after the risk interval.
Results: Increased incidence ratio of an admission for acute MI during risk interval vs. control interval (6.05, 95% CI 3.86-9.50). No increased incidence after 7 d. Increased incidence ratios for acute MI within 7 d after detection of influenza B (10.11, 95% CI 4.37-23.38), influenza A (5.17, 95% CI 3.02-8.84), and respiratory syncytial virus (3.51, 95% CI 1.11-11.12).
Conclusions: Significant association between respiratory infections, especially influenza, and acute MI.

Clinical Features
- incubation period 1-4 d and symptoms typically resolve in 7-10 d
- acute onset of systemic (fever, chills, myalgias, arthralgias, headache, and fatigue) and respiratory symptoms (cough, dyspnea, and pharyngitis)
- complications: respiratory (viral pneumonia, secondary bacterial pneumonia, otitis media, and sinusitis), muscular (rhabdomyolysis, myositis), neurologic (encephalitis, meningitis, transverse myelitis, and Guillain-Barré syndrome)
- severe disease more likely in the elderly, children, pregnant women, immunocompromised patients, asthma, COPD, cardiovascular disease (CVD), DM, and obesity

Investigations
- diagnosis is primarily clinical based on symptoms during the influenza season
- nasopharyngeal swabs for RT-PCR (gold standard), or rapid antigen detection (DFA, direct fluorescent antibody) which has lower sensitivity
- lower respiratory specimens for RT-PCR
- serology: rarely used for clinical management

Treatment and Prevention
- primarily supportive unless severe infection or high-risk for complications
- neuraminidase inhibitors: oseltamivir (Tamiflu®) or zanamivir (Relenza®) for treatment and prophylaxis against types A and B or peramivir (Rapivab™) for the treatment against types A and B
  - decreases duration (by ~1 d) and severity of symptoms if given within 48 h of onset
  - treatment beyond 48 h time window may be warranted in immunosuppressed and critically ill patients
- vaccine for influenza A and B viruses is recommended annually for all ages ≥6 mo
- vaccine is reformulated each year to reflect circulating influenza A and B strains

High-risk for Complications
- anyone who is hospitalized, patients with severe illness/chronic medical conditions, immunocompromised patients, children <2 yr, elders ≥65 yr, pregnant women or women ≤2 wk postpartum

COVID-19

Definitions and Etiology
- an acute infectious respiratory disease caused by the SARS-CoV-2 virus
- SARS-CoV-2 is an enveloped, positive-sense, ssRNA virus
- transmission: droplet and airborne transmission
- incubation period 2-14 d, usually ~5 d

Pathophysiology
- invasion of host cells via the viral spike protein which binds to angiotensin-converting enzyme 2 (ACE2) expressed on the surface epithelium of the lungs
- virus induced cytotoxic damage particularly to the alveolar epithelium
- dysregulated immune response can lead to a cytokine storm causing organ failure or death

Clinical Features
- can be asymptomatic (estimated to be 1 in 3 of those infected)
  - children are more likely to be asymptomatic or to have mild disease
- most common: fever, fatigue, and dry cough
- common: dyspnea, loss of smell and/or taste (may vary depending on the variant circulating), loss of appetite, and myalgia
- less common: nausea, vomiting, abdominal pain, sore throat, headache, and thromboembolic events
- course: can range from mild disease (lasts 1-2 wk) to severe or critical disease (lasts 3+ wk); may be complicated by post-COVID condition which is associated with a wide range of diverse symptoms across multiple organ systems that may fluctuate in intensity, often exacerbated by mental and physical overexertion

Diagnosis
- nasopharyngeal swabs for RT-PCR (gold standard) or nasal/oral-nasal swabs for rapid antigen detection point of care tests which have lower sensitivity
- lower respiratory specimens for RT-PCR

Treatment (accurate as of July 2023)
- please see updated guidance through the Ontario Science Table (https://covid19-sciencetable.ca/science-briefs/#infectious-diseases-clinical-care)

- for critically ill adults >18 yr requiring ventilatory and/or circulatory support:
  - dexamethasone PO or IV for 10 d (or until discharge)
  - tocilizumab if on recommended steroid dose + admitted to hospital or diagnosed with COVID-19 in hospital within 14 d
  - prophylactic low molecular-weight or unfractionated heparin
- for adults >18 yr requiring low-flow supplemental O_2:
  - dexamethasone PO or IV for 10 d (or until discharge)
  - remdesivir IV for 5 d
  - tocilizumab if serum CRP ≥ 75 mg/L + disease progression despite 24-48 h of recommended steroid dose + admitted to hospital or diagnosed with COVID-19 in hospital within 14 d
  - prophylactic low molecular-weight or unfractionated heparin
- for mildly ill adults >18 yr who do not require supplemental O_2 in any setting:
  - stratify by risk of severe disease (i.e. ≥5% risk of hospitalization)
  - for patients with ≥5% risk of hospitalization:
    - nirmatrelvir/ritonavir (Paxlovid) if presenting within 5 d of symptom onset
    - remdesivir if presenting within 7 d of symptom onset
- for patients with <5% risk of hospitalization: reassurance and self-monitoring of symptoms

Table 14. Risk of Hospitalization in Mildly Ill Adults >18 yr with COVID-19 (accurate as of April 1, 2022)

- Higher risk individuals are those who have a ≥5% risk of hospitalization if they develop COVID-19. Standard risk individuals are those who have a <5% of hospitalization.
- Indigenous people, Black people, and members of other racialized communities may be at increased risk of disease progression due to disparate rates of comorbidity, increased barriers to vaccination, and social determinants of health. They should be considered priority populations for access to COVID-19 drugs and therapeutics.

Age (Years)	Number of Vaccine Doses			Risk Factors
	0 Doses	**1 or 2 Doses**	**3 Doses**	Obesity (BMI ≥30 kg/m^2)
<20[1]	**Higher risk** if ≥3 risk factors [1]	Standard risk [1]	Standard risk [1]	Diabetes
20 to 39	**Higher risk** if ≥3 risk factors	**Higher risk** if ≥3 risk factors	Standard risk	Heart disease, hypertension, congestive heart failure
40 to 69	**Higher risk** if ≥1 risk factors	**Higher risk** if ≥3 risk factors	Standard risk	Chronic respiratory disease, including cystic fibrosis
≥70	**Higher risk**	**Higher risk** if ≥1 risk factors	**Higher risk** if ≥3 risk factors	Cerebral palsy
Immunocompromised[2] individuals of any age	**Higher risk**: Therapeutics should always be recommended for immunocompromised individuals not expected to mount an adequate immune response to COVID-19 vaccination or SARS-CoV-2 infection due to their underlying immune status, regardless of age or vaccine status [1,2]			Intellectual disability Sickle cell disease Moderate or severe kidney disease (eGFR <60 mL/min) Moderate or severe liver disease (e.g. Child Pugh, Class B or C cirrhosis)
Pregnancy	**Higher risk**[3]	Standard risk	Standard risk	

1. Evidence for the safety and efficacy of sotrovimab and nirmatrelvir/ritonavir (Paxlovid) in children <18 years of age is limited. While early evidence on risk factors for moderate and severe COVID-19 in children is emerging, the ability to reliably predict disease progression in children remains very limited, and the frequency of progression is rare. While not routinely recommended in children <18 years of age, the use of these agents may be considered in exceptional circumstances (e.g. severe immunocompromise and/or multiple risk factors, clinical progression) on a case-by-case basis. Multidisciplinary consultation with Infectious Diseases (or Pediatric Infectious Diseases) and the team primarily responsible for the child's care is recommended to review the individual consideration of these medications.
2. Examples of immunocompromised or immunosuppressed individuals include receipt of treatment for solid tumours and hematologic malignancies (including individuals with lymphoid malignancies who are being monitored without active treatment), receipt of solid-organ transplant and taking immunosuppressive therapy, receipt of chimeric antigen receptor (CAR)-T-cell or hematopoietic stem cell transplant (within 2 years of transplantation or taking immunosuppression therapy), moderate or severe primary immunodeficiency (e.g. DiGeorge syndrome, Wiskott-Aldrich syndrome, common variable immunodeficiency, Good's syndrome, hyper IgE syndrome), advanced or untreated HIV infection, active treatment with high-dose corticosteroids (i.e. ≥20 mg prednisone or equivalent per day when administered for ≥2 wk), alkylating agents, antimetabolites, transplant-related immunosuppressive drugs, cancer chemotherapeutic agents classified as severely immunosuppressive, tumour-necrosis factor (TNF) blockers, and other biologic agents that are immunosuppressive or immunomodulatory. These individuals should have a reasonable expectation for 1-year survival prior to SARS-CoV-2 infection.
3. Therapeutics should always be recommended for pregnant individuals who have received zero vaccine doses.

Prevention (accurate as of July 2023)

- complete series of mRNA COVID-19 vaccine (Moderna (Spikevax®) or Pfizer-BioNTech (Comirnaty®)) for all ages ≥6 mo who do not have contraindications, with boosters as per public health guidance

Skin and Soft Tissue Infections

Cellulitis

Definition

- acute infection of the skin principally involving the dermis and subcutaneous tissue

Etiology

- common causative agents: β-hemolytic streptococci (most common cause of non-purulent cellulitis), *S. aureus*, and occasionally *S. lugdunensis*
- immunocompromised patients or water exposure: may also include GN rods and fungi
- bite wounds: consider skin flora of "bitee" and mouth flora of "biter"
- risk factors
  - trauma with direct inoculation, recent surgery
  - peripheral vascular disease, lymphedema, DM, and cracked skin in feet/toes (tinea pedis)

Clinical Features

- pain, edema, erythema with indistinct borders ± regional lymphadenopathy, systemic symptoms (fevers, chills, malaise)
- can lead to ascending lymphangitis (visible red streaking in skin along lymphatics proximal to area of cellulitis)

Investigations
- CBC and differential; blood C&S if patient has malignancy, severe systemic features, or unusual predisposing factors, such as immersion injury, animal bites, neutropenia, and severe cell-mediated immunodeficiency
- skin swab ONLY if open wound with pus

Treatment
- consult local guidelines for appropriate antibiotic therapy
- antibiotics: cephalexin (broader coverage if risk factors for GN rods)
- if extensive erythema or systemic symptoms, consider cefazolin IV
- if MRSA is suspected, empiric coverage for MRSA may be considered (see *A Simplified Look at Antibiotics, ID46*)
- limb rest and elevation may help reduce swelling

Necrotizing Fasciitis

Definition
- life- and limb-threatening infection of the deep fascia characterized by rapid spread

Etiology
- two main forms
  - Type I: polymicrobial infection – aerobes and anaerobes (e.g. *S. aureus, Bacteroides, Enterobacterales*)
  - Type II: monomicrobial infection with GAS, or less commonly *S. aureus*

Clinical Features
- pain out of proportion to clinical findings and beyond border of erythema
- edema ± crepitus (subcutaneous gas from anaerobes)
- infection spreads rapidly
- rapid onset of systemic symptoms (e.g. tachycardia, hypotension, lightheadedness, disorientation, lethargy, and fever)
- late findings
  - skin turns dusky blue and black (secondary to thrombosis and necrosis)
  - induration, formation of hemorrhagic bullae
  - loss of sensation in the affected area (paresthesias)

Investigations
- clinical/surgical diagnosis – do NOT wait for results of investigations before beginning treatment
- blood and tissue C&S
- serum creatine kinase (CK) – elevated CK usually means myonecrosis (a late sign)
- plain film x-ray or CT (soft tissue gas may be visualized)
- surgical exploration for debridement of infected tissue

Treatment
- resuscitation with IV fluids
- emergency surgical debridement to confirm diagnosis and remove necrotic tissue (may require amputation)
- IV antibiotics
  - unknown organism: meropenem or piperacillin/tazobactam + clindamycin IV ± vancomycin if MRSA is considered
  - Type I (polymicrobial): piperacillin/tazobactam + clindamycin IV
  - Type II (monomicrobial): with confirmed GAS infection, penicillin G + clindamycin IV; with confirmed S. aureus infection, cefazolin (or cloxacillin) + clindamycin IV
  - with Type II, evaluate for streptococcal toxic shock syndrome and the need for IVIG

Acquired Oral Lesions

Etiology
- infection (e.g. candidiasis, gonococcal infection, and HSV)
- malignancy (e.g. adenocarcinoma, leukoplakia)
- poor oral hygiene (e.g. caries, periodontal disease)
- trauma (e.g. abuse)
- toxic ingestion
- xerostomia (e.g. age, medications)
- systemic diseases (e.g. lichen planus, Behçet disease)

Table 15. Comparison between Oral Infection vs. Oral Carcinoma

	Oral Candidiasis	Oral Squamous Cell Carcinoma
Risk Factors	Antibiotics, chemotherapy, and radiation therapy Immunocompromised, inhaled corticosteroids Age – infants, older adults with dentures	Tobacco use (smoked and smokeless) Betel use Alcohol HPV, especially HPV-16
Morphology	Pseudomembranous: confluent, white patches or plaques, can be wiped off with a gauze, exposing an erythematous base Atrophic candidiasis: red patches localized mainly to the palate and dorsum of the tongue	A lesion of three or more weeks duration: Red or red and white lesion Ulcer Lump Especially when in combination or if indurated (firm on palpation)
Diagnosis	Cytology, biopsy, or culture	Biopsy and histopathologic examination
Treatment	Topical antifungal	Referral to ENT

Gastrointestinal Infections

- see Gastroenterology, G31 and Pediatrics, P44

Traveller's Diarrhea

- see Gastroenterology, G18

Chronic Diarrhea

- see Gastroenterology, G19

Peptic Ulcer Disease *(Helicobacter pylori)*

- see Gastroenterology, G13

Bone and Joint Infections

Septic Arthritis

Definition
- infection of one or more joints by pathogenic microbes

Routes of Infection
- hematogenous (most common)
  - from distant infection (e.g. abscesses, wound infection, and bacteremia)
- direct inoculation via skin/trauma
  - iatrogenic (e.g. surgery, arthroscopy, arthrocentesis, joint injection)
  - trauma (e.g. open wounds around the joint, penetrating trauma)
- contiguous spread (e.g. septic bursitis, osteomyelitis)

Etiology
- gonococcal
  - *N. gonorrhoeae*: previously accounted for 75% of septic arthritis in young sexually active adults
- non-gonococcal
  - *S. aureus*: affects all ages, rapidly destructive, accounts for most non-gonococcal cases of septic arthritis in adults (especially in those with rheumatoid arthritis)
  - *Streptococcus* spp. (Group A and B)
  - GNs: affect neonates, elderly, injection drug users, immunocompromised
  - *S. pneumoniae*: affects children
  - *Kingella kingae*: affects children <4 yr
  - *Haemophilus influenzae* type B (Hib) now rare due to Hib vaccine: consider in unvaccinated children
  - *Salmonella* spp.: characteristic of sickle cell disease
  - coagulase-negative *Staphylococcus* spp.: prosthetic joints
- if culture-negative: partially treated infection (prior to oral antibiotics), reactive arthritis, rheumatic fever, less common bacterial causes such as *Borrelia* spp. (Lyme disease) or *Tropheryma whipplei* (Whipple's disease), and non-infectious causes

Medical Emergency
Septic arthritis is a medical emergency! If untreated, rapid joint destruction will occur

Disseminated Gonococcal Infection Triad
Migratory arthralgias
Tenosynovitis next to inflamed joint
Pustular skin lesions

Risk Factors
- gonococcal
- age <40 yr, multiple partners, unprotected intercourse, MSM
- non-gonococcal
  - most affected children are previously healthy with no risk factors: occasionally preceding history of minor trauma
  - bacteremia (extra-articular infection with hematogenous seeding, endocarditis)
  - prosthetic joints/recent joint surgery
  - underlying joint disease (e.g. rheumatoid arthritis, osteoarthritis)
  - immunocompromised (e.g. DM, chronic kidney disease, alcohol use disorder, cirrhosis)
  - loss of skin integrity (e.g. cutaneous ulcer, skin infection)
  - age >80 yr

Intra-articular steroids are contraindicated until septic arthritis has been excluded

Clinical Features of Gonococcal Arthritis
- two forms (although often overlap):
  - septic arthritis form: local symptoms in involved joint (swelling, warmth, pain, inability to weight bear, decreased range of motion)
  - bacteremic form: systemic symptoms of fever, malaise, chills

Clinical Features of Non-Gonococcal Arthritis
- acute onset of pain, swelling, warmth, decreased range of motion ± fever and chills; in children, refusal to weight bear
- most often in large weight-bearing joints (knee, hip, ankle) and wrists
- usually monoarticular (polyarticular risk factors: rheumatoid arthritis, endocarditis, GBS)

Investigations
- consider rheumatologic causes for monoarthritis (see Rheumatology, Table 4, RH5)
- gonococcal: blood C&S, as well as endocervical, urethral, rectal, and oropharyngeal testing
- non-gonococcal: blood C&S
- arthrocentesis (synovial fluid analysis) is mandatory, CBC and differential, Gram stain, C&S, examine for crystals
  - infectious = opaque, increased WBCs (>15000/mm ^{3}; likelihood of infection increases with increasing WBCs), PMNs >90%, culture positive
  - growth of *N. gonorrhoeae* from synovial fluid is successful in <50% of cases
- ± plain x-ray: assess for osteomyelitis, provides baseline to monitor treatment

IWGDF Guidance on the Diagnosis and Management of Foot Infections in Persons with Diabetes - Recommendations for Diagnosing Osteomyelitis
Diabetes Metab Res Rev 2016;32:45-74
Perform a probe-to-bone test for an infected open wound; a negative test likely rules out osteomyelitis in low-risk patients, while a positive test is likely diagnostic in high-risk patients.
In suspected cases, dramatically elevated serum inflammatory markers (especially ESR) are suggestive of osteomyelitis.
When in doubt, positive results on microbiological or histological exam of an aseptic bone sample are usually required for a definitive diagnosis of bone infection.
Bone infection is probable if there are positive results on a combination of diagnostic tests (probe-to-bone, serum inflammatory markers, plain x-ray, MRI, or radionuclide scanning).
For all cases of non-superficial diabetic foot infection, plain x-rays of the foot should be obtained.
When advanced imaging is required for diagnosis, MRI is preferred.

Treatment
- medical
  - empiric IV antibiotics: specific choice depends on clinical scenario and local guidelines; for most adults, cefazolin ± vancomycin is reasonable; for fully vaccinated children, cefazolin or cloxacillin IV unless MRSA is a consideration – delay may result in joint destruction
  - Gram stain and cultures guide subsequent treatment
  - gonococcal: ceftriaxone (+ azithromycin for concurrent treatment of *C. trachomatis*), 7 d of therapy usually sufficient
  - non-gonococcal: antibiotics against *Streptococcus* spp. (2-3 wk IV followed by PO), *S. aureus* (4 wk IV minimum), or GNB (4 wk, newer evidence suggests early switch to PO is safe and effective)
- surgical intervention if (see Orthopedic Surgery, OR11)
  - would consider surgical intervention on all cases of septic arthritis if possible
  - persistent positive joint cultures on repeat arthrocentesis
  - hip joint involvement, especially in paediatric population
  - prosthetic joint
- daily joint aspirations until culture sterile
- physiotherapy

See Landmark Infectious Disease Trials table for more information on the OVIVA trial. It details whether oral antibiotic therapy is noninferior to IV antibiotic therapy for the management of complex orthopaedic infections.

Prognosis
- gonococcal: responds well after 24-48 h of initiating antibiotics (usually complete recovery)
- non-gonococcal: in children, generally good outcome if treated promptly; in adults, up to 50% morbidity (decreased joint function/mobility)

Diabetic Foot Infections

Etiology
- neuropathy, peripheral vascular disease, and hyperglycemia contribute to foot ulcers that heal poorly, and are predisposed to infection
- organisms in mild infection: *Streptococcus* spp., *S. aureus*
- organisms in moderate/severe infection: polymicrobial with aerobes (*S. aureus, Streptococcus, Enterococcus*, GNB) and anaerobes (*Peptostreptococcus, Bacteroides, Clostridium*)

Clinical Features
- not all ulcers are infected
- consider infection if: probe to bone (see below), ulcer present >30 d, recurrent ulcers, trauma, PVD, prior amputation, loss of protective sensation, renal disease, or history of walking barefoot

- diagnosis of infected ulcer: ≥2 of the cardinal signs of inflammation (redness, warmth, swelling, pain) OR the presence of pus
- ± crepitus, osteomyelitis, systemic toxicity
- visible bone or probe to bone: osteomyelitis
- infection severity
  - mild = superficial (no bone/joint involvement)
  - moderate = deep (beneath superficial fascia, involving bone/joint) or erythema >2 cm
  - severe = infection in a patient with systemic toxicity (fever, tachypnea, leukocytosis, tachycardia, hypotension)

Investigations
- curettage specimen from ulcer base, aspirate from an abscess or bone biopsy (results from superficial swabs do not represent organisms responsible for deeper infections)
- blood C&S if febrile
- assess for osteomyelitis by x-ray (although not sensitive in early stages) or MRI/bone scan if high clinical suspicion
- if initial x-ray normal, repeat 2-4 wk after initiating treatment to increase test sensitivity

Treatment
- mild to moderate: cefazolin or cephalexin
- severe: options include: 1. ceftriaxone + metronidazole; 2. piperacillin/tazobactam ± vancomycin; 3. meropenem ± vancomycin
- optimize glycemic control, pressure offloading, wound care, consider revascularization
  - this is empiric treatment, and specific treatment needs to be adjusted based on culture and response to therapy

Osteomyelitis

- see Orthopedic Surgery, OR11

Cardiac Infections

Infective Endocarditis

Definition
- infection of cardiac endothelium, most commonly the valves
- classifications: acute vs. subacute, native valve vs. prosthetic valve, right sided vs. left sided
- leaflet vegetations are made of platelet-fibrin thrombi, WBCs, and bacteria

Risk Factors and Etiology
- predisposing conditions
  - high-risk: prosthetic cardiac valve, previous infective endocarditis (IE), congenital heart disease (unrepaired, repaired within 6 mo, or repaired with defects), cardiac transplant with valve disease (surgically constructed systemic-to-pulmonary shunts or conduits)
  - moderate risk: other congenital cardiac defects, acquired valvular dysfunction, hypertrophic cardiomyopathy
  - low/no risk: secundum atrial septal defect (ASD) or surgically repaired ASD, ventricular septal defect (VSD), patent ductus arteriosus (PDA), mitral valve (MV) prolapse, ischemic heart disease, previous coronary artery bypass graft (CABG)
  - opportunistic bacteremia: IVDU, indwelling venous catheter, hemodialysis, poor dentition, DM, HIV
- frequency of valve involvement MV>>aortic valve (AV)>tricuspid valve (TV)>pulmonary valve (PV)
  - in 50% of IVDU-related IE the tricuspid valve is involved

Table 16. Microbial Etiology of Infective Endocarditis Based on Risk Factors

Native Valve	IVDU	Prosthetic Valve (recent surgery <2 mo)	Prosthetic Valve (remote surgery >2 mo)
***Streptococcus*[1] (36%)**	***S. aureus* (68%)**	***S. aureus* (36%)**	***Streptococcus* (20%)**
***S. aureus* (28%)**	***Streptococcus* (13%)**	***S. epidermidis* (17%)**	***S. aureus* (20%)**
***Enterococcus* (11%)**	*Enterococcus*	*Enterococcus*	***S. epidermidis* (20%)**
S. epidermidis	GNB	GNB	***Enterococcus* (13%)**
GNB	*Candida*	Other[2]	Other[2]
Other[2]	Other[3]		

Organisms in bold are the most common isolates
1. *Streptococcus* includes mainly viridans group streptococci
2. Other includes less common organisms such as:
   - *Streptococcus gallolyticus* (previously known as *S. bovis*; usually associated with underlying GI malignancy and cirrhosis)
   - Culture-negative organisms including *Abiotrophia, Granulicatella, Bartonella, Coxiella, Chlamydia, Legionella, Brucella*
   - *Haemophilus, Aggregatibacter, Cardiobacterium, Eikenella*, and *Kingella* (HACEK)
   - *Candida*
3. IVDU endocarditis pathogens depend on substance used to dilute the drugs (i.e. tap water = *Pseudomonas*, saliva = oral flora, toilet water = GI flora)

Clinical Features
- systemic
  - fever (80-90%), chills, weakness, rigors, night sweats, weight loss, anorexia

- cardiac
  - dyspnea, chest pain, clubbing (subacute)
  - regurgitant murmur (new onset or increased intensity)
  - signs of CHF (secondary to acute mitral regurgitation (MR), atrial regurgitation (AR))
- embolic/vascular
  - petechiae over legs, splinter hemorrhages (linear, reddish-brown lesion within nail bed)
  - Janeway lesions (painless, 5 mm, erythematous, hemorrhagic pustular lesions on soles/palms)
  - focal neurological signs (CNS emboli), headache (mycotic aneurysm)
  - splenomegaly (subacute)
  - microscopic hematuria, flank pain (renal emboli) ± active sediment
- immune complex
  - Osler's nodes (painful, raised, red/brown, 3-15 mm on digits)
  - glomerulonephritis
  - arthritis
  - Roth's spots (retinal hemorrhage with pale centre)

Clinical Features of Infective Endocarditis

FROM JANE
Fever
Roth's spots
Osler's nodes
Murmur
Janeway lesions
Anemia
Nail-bed hemorrhages (i.e. splinter hemorrhages)
Emboli

Diagnosis

- Modified Duke Criteria
  - definitive diagnosis if: 2 major, OR 1 major + 3 minor, OR 5 minor
  - possible diagnosis if: 1 major + 1 minor, OR 3 minor

Table 17. Modified Duke Criteria

Major Criteria (2)
1. Positive blood cultures for IE • Typical microorganisms for IE from 2 separate blood cultures (*Streptococcus viridans*, HACEK group, *Streptococcus gallolyticus, Staphylococcus aureus*, community-acquired enterococci) OR • Persistently positive blood culture, defined as recovery of a microorganism consistent with IE from blood drawn >12 h apart OR • All of 3 or a majority of 4 or more separate blood cultures, with first and last drawn >1 h apart OR • Single positive blood culture for *Coxiella burnetii* or antiphase 1 IgG antibody titer >1:800 2. Evidence of endocardial involvement • Positive echocardiogram for IE (oscillating intracardiac mass on valve or supporting structures, or in the path of regurgitant jets, or on implanted material in the absence of an alternative anatomic explanation OR abscess OR new partial dehiscence of prosthetic valve); and new valvular regurgitation (insufficient if increase or change in pre-existing murmur)
Minor Criteria (5)
1. Predisposing condition (abnormal heart valve, IVDU) 2. Fever (38.0°C/100.4°F) 3. Vascular phenomena: major arterial emboli, septic pulmonary infarcts, mycotic aneurysms, intracerebral hemorrhage (ICH), conjunctival hemorrhages, Janeway lesions 4. Immunologic phenomena: glomerulonephritis, rheumatoid factor, Osler's nodes, Roth's spots 5. Positive blood culture but not meeting major criteria OR serologic evidence of active infection with organism consistent with IE

TEE Transesophageal echo
TTE Transthoracic echo

Investigations

- serial blood cultures: 3 sets (each containing one aerobic and one anaerobic sample) collected from different sites >1 h apart
  - persistent bacteremia is the hallmark of an endovascular infection (e.g. IE)
- repeat blood cultures (at least 2 sets) after 48-72 h of appropriate antibiotics to confirm clearance
- blood work: CBC and differential (normochromic, normocytic anemia), erythrocyte sedimentation rate (ESR) (increased), rheumatoid factor (RF) (+), urea/Cr
- urinalysis (proteinuria, hematuria, red cell casts) and urine C&S
- ECG: prolonged PR interval may indicate perivalvular abscess
- echo findings: vegetations, regurgitation, abscess
  - TTE (poor sensitivity) indicated for all suspected IE, inadequate in 20% (obesity, COPD, chest wall deformities)
  - TEE indicated if TTE is non-diagnostic in patients with at least possible endocarditis or if suspect prosthetic valve endocarditis or complicated endocarditis (e.g. paravalvular abscess/perforation) (~90% sensitivity)

Treatment

- medical
  - usually non-urgent and can wait for confirmation of etiology before initiating treatment unless patient is septic
  - empiric antibiotic therapy if patient is unstable; administer ONLY after blood cultures have been taken. Generally, *S. aureus*, coagulase-negative *Staphylococcus* (CNST), and GN coverage is important
    - first line empiric treatment for native valve: vancomycin + ceftriaxone OR gentamicin
    - first line empiric treatment for prosthetic valve: vancomycin + gentamicin + rifampin
  - targeted antibiotic therapy: antibiotic and duration (usually 4-6 wk) adjusted based on valve, organism, and susceptibilities
  - monitor for complications of IE (e.g. heart failure (HF), conduction block, new emboli) and complications of antibiotics (e.g. renal disease)
  - post-treatment prophylaxis only recommended for high-risk individuals listed above with dental procedures that may lead to bleeding OR invasive procedure of the respiratory tract that involves incision or biopsy of the respiratory mucosa, such as tonsillectomy and adenoidectomy OR procedures on infected skin, skin structure, or musculoskeletal tissue

- dental/respiratory procedures: amoxicillin single dose 30-60 min prior; clindamycin if truly penicillin-allergic
- infected skin/soft tissue procedures: cephalexin single dose 30-60 min prior; clindamycin if truly penicillin-allergic (modify based on etiology of skin/soft tissue infection)

- surgical
  - most common indication is refractory CHF
  - other indications include: valve ring abscess, valve perforation, unstable prosthesis, large vegetation >1 cm, recurrent emboli despite adequate antimicrobial treatment, antimicrobial failure (persistently positive blood cultures), fungal etiology, *S. aureus* on a prosthetic valve

Prognosis

- adverse prognostic factors: CHF, prosthetic valve infection, valvular/myocardial abscess, embolization, persistent bacteremia, altered mental status
- mortality: prosthetic valve IE (25-50%), non-IVDU *S. aureus* IE (30-45%), IVDU *S. aureus* or streptococcal IE (10-15%)

CNS Infections

Meningitis

- see Pediatrics, P65

Definition

- inflammation of the meninges

Etiology

Table 18. Common Organisms in Meningitis

Bacterial			Viral	Fungal	Other
Age 0-4 wk	**Age 1-3 mo**	**Age >3 mo**			
GBS *E. coli* *L. monocytogenes* *Klebsiella*	GBS *E. coli* *S. pneumoniae* *N. meningitidis* *H. influenzae*	*S. pneumoniae* *N. meningitidis* *L. monocytogenes* (likely if age >50 and comorbidities)	HSV-1, 2 VZV Enteroviruses Parechoviruses West Nile	Cryptococcus Coccidioides	Lyme disease Neurosyphilis TB

Risk Factors

- lack of immunization against *H. influenzae* type B, *S. pneumoniae*, and *N. meningitidis* in children
- most cases of bacterial meningitis are due to hematogenous spread from a mucosal surface (nasopharynx)
- direct extension from a parameningeal focus (otitis media, sinusitis) less common
- penetrating head trauma or iatrogenic
- anatomical meningeal defects – CSF leaks
- immunodeficiency (e.g. corticosteroids, HIV, asplenia, hypogammaglobulinemia, complement deficiency, etc.)
- contact with colonized or infected persons

Clinical Features

- neonates and children: fever, lethargy, irritability, vomiting, poor feeding
- older children and adults: fever, headache, neck stiffness, confusion, lethargy, altered LOC, seizures, focal neurological signs, nausea/vomiting, photophobia, papilledema
- petechial rash in meningococcal meningitis (purpura fulminans), seen more frequently on trunk or lower extremities

Investigations

- blood work: CBC and differential, electrolytes (for SIADH), blood C&S
  - CSF: opening pressure, cell count + differential, glucose, protein, Gram stain, bacterial C&S
  - AFB, fungal C&S, cryptococcal antigen in immunocompromised patients, subacute illness, suggestive travel history or TB exposure
  - PCR for HSV, VZV, enteroviruses; in infants <6 mo, parechoviruses
  - West Nile virus serology in blood and CSF during summer and early fall if viral cause suspected
- imaging/neurologic studies: CT, MRI, EEG if focal neurological signs present

Table 19. Typical CSF Profiles for Meningitis

CSF Analysis	Bacterial	Viral
Glucose (mmol/L)	Decreased	Normal
Protein (g/L)	Markedly increased	Increased
WBC	500-10000/μL	10-500/μL
Predominant WBC	Neutrophils	Lymphocytes

See Landmark Infectious Diseases Trials for more information on the POET trial, which investigated the efficacy and safety of shifting from IV to oral antibiotics in patients with IE.

Corticosteroids for Acute Bacterial Meningitis
Cochrane DB Syst Rev 2015;CD004405
Purpose: To examine the effect of adjuvant corticosteroid therapy vs. placebo on mortality, hearing loss, and neurological sequelae with acute bacterial meningitis.
Methods: RCTs of corticosteroids for acute bacterial meningitis.
Results: 25 studies, 4121 participants. Corticosteroids were associated with non-significant mortality reductions (RR 0.90, 95% CI 0.80-1.01). Corticosteroids were associated with lower rates of hearing loss (RR 0.74, 95% CI 0.63-0.87) and neurological sequelae (RR 0.83, 95% CI 0.69-1.00). Corticosteroids were associated with increase in recurrent fever (RR 1.27, 95% CI 1.09-1.47).
Conclusions: Corticosteroids significantly reduced hearing loss and neurological sequelae but did not reduce mortality. Data supports use in high-income countries but no benefit in low-income countries.

Brudzinski's Sign
Passive neck flexion causes involuntary flexion of hips and knees

Kernig's Sign
Resistance to knee extension when hip is flexed to 90°

Jolt Accentuation of Headache
Headache worsens when head turned horizontally at 2-3 rotations; more sensitive than Brudzinski's and Kernig's

CSF Gram Stain Findings
- *S. pneumoniae* – GP diplococci
- *N. meningitidis* – GN diplococci
- *H. influenzae* – Pleomorphic GN coccobacilli
- *L. monocytogenes* – GP rods

Does this Adult Patient have Acute Meningitis?
JAMA 1999;281:175-181
Study: Systematic review of literature analyzing the accuracy and precision of the clinical examination in the diagnosis of adult meningitis.
Results: Clinical history items have a low accuracy for the diagnosis of meningitis in adults. The sensitivity for headaches is 50% and the sensitivity for nausea/vomiting is 30%. On physical examination, absence of fever, neck stiffness, and altered mental status eliminates meningitis with a sensitivity of 99%.
Conclusions: The clinical examination aids in excluding a diagnosis of meningitis in adults with a low-risk clinical presentation. In high-risk patients, clinicians need to proceed directly to lumbar puncture given the serious implications of the infection.

Treatment
- bacterial meningitis is a medical emergency: do not delay antibiotics for CT or LP
- empiric antibiotic therapy
  - age ≤28 d: ampicillin + cefotaxime
  - age 29 d-3 mo: ceftriaxone/cefotaxime + vancomycin ± ampicillin
  - age >3 mo: ceftriaxone + vancomycin
    - add ampicillin IV if risk factors for infection with L. monocytogenes present: age >50, alcohol use disorder, immunocompromised
- steroids in acute bacterial meningitis: dexamethasone IV within 20 min prior to or with first dose of antibiotics
  - continue in those patients with proven pneumococcal meningitis
  - not recommended for patients with suspected bacterial meningitis in some resource-limited countries
  - not recommended for neonatal meningitis

Prevention
- see Pediatrics, P65
- immunization
  - children: immunization against *H. influenzae* type B (Pentacel®), *S. pneumoniae* (Synflorix®, Prevnar-13®), *N. meningitidis* (Menjugate®, Menactra®, Nimenrix®, Menveo®, Bexsero®)
  - adults: immunization against *N. meningitidis* in selected circumstances (immunocompromised, outbreaks, travel, epidemics) and *S. pneumoniae* (Pneumovax®) for high-risk groups
- prophylaxis: close contacts of patients infected with H. influenzae type B should be treated with rifampin if they live with an inadequately immunized (<4 yr) or immunocompromised child (<18 yr); ciprofloxacin, rifampin, or ceftriaxone if close or household contact of a patient with *N. meningitidis*; meningococcal vaccines are also recommended for post-exposure prophylaxis for close contacts and in outbreak control

Prognosis
- complications
  - death, headache, seizures, cerebral edema, hydrocephalus, SIADH, residual neurological deficit (especially CN VIII), deafness
- mortality
  - *S. pneumoniae* 25%; *N. meningitidis* 5-10%; *H. influenzae* 5%
  - worse prognosis if: extremes of age, delays in diagnosis and treatment, stupor or coma, seizures, focal neurological signs, septic shock at presentation

Encephalitis

Definition
- inflammation of the brain parenchyma

Etiology
- identified in only 40-70% of cases
  - when cause is identified, the most common etiology is viral: HSV, VZV, EBV, CMV, enteroviruses, parechoviruses, West Nile and other arboviruses, influenza and other respiratory viruses, HIV, mumps, measles, rabies, polio
  - bacteria: *L. monocytogenes*, mycobacteria, spirochetes (Lyme, syphilis), *Mycoplasma pneumoniae*
  - parasites: protozoa (e.g. *Toxoplasma*) and helminths (rare)
  - fungi: e.g. *Cryptococcus*
  - post-infectious (e.g. acute disseminated encephalomyelitis (ADEM))

Pathophysiology
- acute inflammatory disease of the brain due to direct invasion or pathogen-initiated immune response viruses may reach the CNS via peripheral nerves (e.g. rabies, HSV)
- herpes simplex encephalitis
  - acute, necrotizing, asymmetrical hemorrhagic process with lymphocytic and plasma cell reaction which usually involves the medial, temporal, and inferior frontal lobes
  - associated with HSV-1, less likely caused by HSV-2
- influenza and other respiratory viruses are associated with acute necrotizing encephalopathy (ANE); likely mediated by pathogen-initiated immune response

Clinical Features
- constitutional: fever, chills, malaise, nausea/vomiting
- meningeal involvement (meningoencephalitis): headache, nuchal rigidity
- parenchymal involvement: seizures, altered mental status, focal neurological signs
- herpes simplex encephalitis
  - acute onset (<1 wk) of focal neurological signs: hemiparesis, ataxia, aphasia, focal or generalized seizures
  - temporal lobe involvement: behavioural disturbance
  - usually rapidly progressive over several days and may result in coma or death
  - common sequelae: memory and behavioural disturbances
  - rare complication: development of encephalopathy and Kluver-Bucy syndrome characteristics 1 mo after completion of treatment for HSV encephalopathy

Public Health Agency of Canada Indications for Adult Immunization

Pneumococcal Polysaccharide Vaccine (i.e. Pneumovax®)
≥65 yr (option to also give pneumococcal conjugate vaccine; if so, to give polysaccharide vaccine 8 wk after conjugate vaccine)

Pneumococcal Polysaccharide Vaccine (i.e. Pneumovax®) and Pneumococcal Conjugate Vaccine
Chronic cardiovascular/respiratory/hepatic/renal disorders, asplenia, sickle cell, or immunosuppression (polysaccharide vaccine to be given 8 wk after pneumococcal conjugate vaccine)

Meningococcal Quadrivalent Vaccine (Menactra® or Menomune®)
Healthy young adults
Asplenia
Travellers to high-risk areas
Military recruits or laboratory personnel
Complement, factor D, or properdin deficiency or acquired terminal complement deficiency through receipt of eculizumab

Multicomponent Meningococcal Serogroup B Vaccine (Bexsero®)
Asplenia
Military recruits or laboratory personnel
Complement, factor D, or properdin deficiency, or acquired terminal complement deficiency through receipt of eculizumab

Meningitis and encephalitis patients can be distinguished based on their cerebral function. Cerebral function is abnormal in encephalitis patients (e.g. altered mental status, motor or sensory deficits, altered behaviour, speech or movement disorders), but may be normal in patients with meningitis. Note however, that there is considerable overlap between the two syndromes ("meningoencephalitis")

Investigations
- CSF: opening pressure, cell count and differential, glucose, protein, Gram stain, bacterial C&S, PCR for HSV, VZV, EBV, enteroviruses/parechoviruses, *M. pneumoniae*, and selectively for other less common etiologies
- serology: may aid diagnosis of certain causes of encephalitis (e.g. EBV, West Nile virus, rabies, *Bartonella henselae*)
- imaging/neurologic studies: CT, MRI, EEG to define affected anatomical sites
- invasive testing: brain tissue biopsy may be required for culture, histological examination, and immunocytochemistry (if diagnosis not clear via non-invasive means)
- findings in herpes simplex encephalitis (must rule out due to high mortality)
  - CT/MRI: medial temporal lobe necrosis
  - EEG: early focal slowing, periodic discharges

Treatment
- general supportive care
- monitor vital signs carefully
- IV acyclovir empirically until HSV encephalitis ruled out

Generalized Tetanus

Etiology and Pathophysiology
- caused by *Clostridium tetani*: motile, spore forming, anaerobic GP bacillus
- found in soil, splinters, rusty nails, GI tract (humans and animals)
- traumatic implantation of spores into tissues with low oxygenation (e.g. puncture wounds, burns, non-sterile surgeries, or deliveries)
- upon inoculation, spores develop into *C. tetani* bacilli that produce tetanus toxins
  - toxin travels via retrograde axonal transport to the CNS where it irreversibly binds presynaptic neurons to prevent the release of inhibitory neurotransmitters (e.g. GABA)
  - net effect is the disinhibition of spinal motor reflexes which results in tetany and autonomic hyperactivity

Clinical Features
- generalized tetanus
  - initially present with painful spasms of masseters (trismus or "lockjaw")
  - sustained contraction of skeletal muscle with periodic painful muscle spasms (triggered by sensory stimuli, e.g. loud noises)
  - paralysis descends to involve large muscle groups (neck, abdomen)
  - apnea, respiratory failure, and death secondary to tonic contraction of pharyngeal and respiratory muscles
- autonomic hyperactivity
  - diaphoresis, tachycardia, HTN, fever as illness progresses

Antimicrobial therapy (e.g. metronidazole) may fail to treat C. tetani unless adequate wound debridement is performed

Investigations
- primarily a clinical diagnosis, often although not always with a history of a traumatic wound and lack of immunization
- culture wounds, CK may be elevated

Treatment
- stop toxin production
  - wound debridement to clear necrotic tissue and spores
  - antimicrobial therapy: IV metronidazole (effective alternative: IV penicillin G)
- neutralize unbound toxin with tetanus immune globulin (TIg)
- supportive therapy: intubation, spasmolytic medications (benzodiazepines), quiet environment, cooling blanket

control autonomic dysfunction: α- and β-blockade (e.g. labetalol), magnesium sulfate

Prevention
- infection with *C. tetani* does not produce immunity – vaccinate patients on diagnosis
- tetanus toxoid vaccination (see Pediatrics, P65 and Emergency Medicine, ER17)

Rabies

Definition
- acute progressive encephalitis caused by RNA virus (genus Lyssavirus of the Rhabdoviridae family)

Etiology and Pathophysiology
- any mammal can transmit the rabies virus
  - most commonly transmitted by raccoons, skunks, bats, foxes, cats, and dogs; monkeys also a risk in the tropics and sub-tropics
- transmission: breaching of skin by teeth or direct contact of infectious tissue (saliva, neural tissue) with skin or mucous membranes
  - almost all cases due to bites
  - animals can be carriers for several days before manifest signs of disease

- virus travels via retrograde axonal transport from PNS to CNS
- virus multiplies rapidly in brain, then spreads to other organs, including salivary glands
- development of clinical signs occurs simultaneously with excretion of rabies virus in saliva
  - infected animal can transmit rabies virus as soon as it shows signs of disease

Clinical Features
- five stages of disease
  1. incubation period
     - 1-3 mo on average (can range from days to years, depending on distance from bite site to CNS)
  2. prodrome (<1 wk)
     - low-grade fever, malaise, anorexia, nausea/vomiting, headache, sore throat
     - pain, pruritus, and paresthesia may occur at wound site
     - once prodromal symptoms develop, there is rapid, irreversible progression to death
       - progression from prodrome to coma and death may occur without an intervening acute neurologic syndrome
  3. acute neurologic syndrome: 2 types (<1 wk)
     a. encephalitic (most common): hyperactivity, fluctuating LOC, hydrophobia, aerophobia, hypersalivation, fever, seizures
       - painful pharyngeal spasms on encountering gust of air or swallowing water cause aerophobia and hydrophobia, respectively

     b. paralytic: quadriplegia, loss of anal sphincter tone, fever
  4. coma
     - complete flaccid paralysis, respiratory, and cardiovascular failure
  5. death (within days to weeks of initial symptoms)

Investigations
- purpose of diagnosis by investigations is to limit patient contact with others and to identify others exposed to the infectious source
- antemortem: direct immunofluorescence or PCR on multiple specimens: saliva, skin biopsy, serum, CSF
- post-mortem: direct immunofluorescence in nerve tissue, presence of Negri bodies (inclusion bodies in neurons)

Treatment
- post-exposure prophylaxis depends on regional prevalence and circumstances surrounding injury
- mandatory to report animal bite/contact that may result in rabies to Public Health Authority
- if not previously immunized:
  - wound care: clean wound promptly and thoroughly with soap and running water for 15 min
  - passive immunization: rabies immunoglobulin (RIG) infiltrated into wound site, with any remaining volume administered IM in anatomical site distant from vaccine administration
    - due to variable response rates, vaccine should not be administered into gluteal muscle
  - active immunization: inactivated human diploid cell rabies virus vaccine (HDCV) – series of 4 shots post-exposure on d 0, 3, 7, and 14
    - vaccine administered into deltoid
- if previously immunized:
  - wound care: clean wound promptly and thoroughly with soap and running water for 15 min
  - two doses of HDCV into deltoid on d 0 and 3
  - no RIG administered
- treatment is supportive once victim manifests signs and symptoms of disease

Prevention
- pre-exposure vaccination
  - recommended for high-risk persons: laboratory staff working with rabies, veterinarians, animal and wildlife control workers, long-term travellers to endemic areas

Systemic Infections

Sepsis and Septic Shock

- see Respirology, R32

Definitions
- bacteremia: bacteria in blood from primary bloodstream infection or secondary to infection of another body system
- sepsis: severe organ dysfunction resulting from dysregulated host response to infection
  - organ dysfunction identified via acute change in SOFA score ≥2 points
  - qSOFA score used initially to screen patients for suspected sepsis using three criteria:
    1. respiratory rate ≥22/min
    2. sBP ≤100 mmHg
    3. altered mentation (GCS <15)
- septic shock: subset of sepsis with circulatory and cellular/metabolic dysfunction; clinically defined in cases where despite adequate volume resuscitation there is both
    1. persistent hypotension requiring vasopressors to maintain MAP ≥65 mmHg AND
    2. serum lactate >2 mmol/L

SOFA score >2 = 10% mortality risk in patient with suspected infection
Hospital mortality with septic shock >40%

qSOFA score
1. Respiratory rate ≥22/min
2. sBP ≤100 mmHg
3. Altered mentation (GCS <15)

Pathophysiology
- causative agents are identified in only 50-70% of cases
- when organisms are identified, GP and GN organisms are the cause in 90% of cases
- bacteremia → local immune response → pro-inflammatory cytokine release → spread of immune response beyond local environment → unregulated, exaggerated systemic immune response → vasodilation and hypotension → distributive shock and reduced O_2 delivery to tissues → anaerobic metabolism and lactic acid production → metabolic acidosis → multiple organ failure

The Third International Consensus Definitions for Sepsis and Septic Shock (Sepsis-3) in 2016 re-defined sepsis using the Sequential Organ Failure Assessment (SOFA) score for diagnosis and Quick-SOFA (qSOFA) for screening of end-organ failure. The terms severe sepsis and systemic response inflammatory response syndrome (SIRS) are no longer part of the sepsis definition

Clinical Features
- history: symptoms and signs specific to an infectious source (e.g. cough, headache, dysuria, purulent exudate, rash)
- general symptoms of infection: fever, chills, pain, dyspnea, cool extremities, fatigue, malaise, anxiety, confusion
- physical: abnormal vitals (e.g. fever, tachypnea, tachycardia, hypotension), flushed skin, altered mental status, local signs of infection (e.g. pharyngitis, septic arthritis, neck stiffness, skin wounds/ulcers, or murmurs)

Investigations
- CBC and differential, electrolytes, urea, creatinine, liver enzymes, ABG, lactate, INR, PTT, troponin, blood C&S x2, urinalysis, urine C&S, and cultures of any wounds or lines
- CXR (other imaging depends on suspicion of focus of infection)
- nasopharyngeal swab/stool/sputum cultures, throat swabs, genital swab, LP as indicated

Treatment (see Respirology, R32)
- respiratory support: O_2 ± intubation
- cardiovascular support: IV fluids ± blood transfusion + vasopressors + ICU
- IV antibiotics (empirical, guided by suspected source)
  - consider broad spectrum antibiotics (e.g. piperacillin/tazobactam or meropenem) ± additional agents depending on patient risk factors, suspected etiology or focus of infection, and local microbial susceptibilities (± aminoglycoside for drug-resistant Gram-negatives or vancomycin for MRSA)
  - breadth of empiric coverage should take into account: i) estimated adequacy of spectrum of activity and ii) degree of instability or severity of infection
  - narrow once organism and susceptibilities are known
- source control: procedure to control focus of infection (catheter removal, abscess drainage)
- hydrocortisone IV may be added in patients with septic shock unresponsive to fluid resuscitation and vasopressors

Leprosy (Hansen's Disease)

Etiology
- *Mycobacterium leprae*: obligate intracellular bacteria, slow-growing (doubling time 12.5 d), survives in macrophages
- bacteria transmitted from nasal secretions, potentially via skin lesions
- invades skin and peripheral nerves leading to chronic granulomatous disease

Clinical Features
- lesions involve cooler body tissues (e.g. skin, superficial nerves, nose, eyes, larynx)
- spectrum of disease determined by host immune response to infection
  - i. paucibacillary "tuberculoid" leprosy (intact cell-mediated immune response)
    - ≤5 hypoesthetic lesions, usually hypopigmented, well-defined, dry
    - early nerve involvement, enlarged peripheral nerves, neuropathic pain
    - may be self-limited, stable, or progress over time to multibacillary "lepromatous" form
  - ii. multibacillary "lepromatous" leprosy (weak cell-mediated immune response)
    - ≥6 lesions, symmetrical distribution
    - leonine facies (nodular facial lesions, loss of eyebrows, thickened ear lobes)
    - extensive cutaneous involvement, late and insidious nerve involvement causing sensory loss at the face and extremities
  - iii. borderline leprosy
    - lesions and progression lie between tuberculoid and lepromatous forms

Investigations
- skin biopsy down to fat or slit skin smears for AFB staining, PCR
- histologic appearance: intracellular bacilli in spherical masses (lepra cells), granulomas involving cutaneous nerves

Treatment
- regimens based on WHO recommendations
- paucibacillary: dapsone daily + rifampin monthly + clofazimine monthly AND low dose clofazimine once daily x 6 mo
- multibacillary: dapsone daily + rifampin monthly + clofazimine monthly x 12 mo AND low dose clofazimine once daily for 12 mo

- treatment of leprosy (along with other precipitants of immune responsiveness such as viral illness, immunization, hormonal fluctuations of pregnancy, and parturition) can cause an immune reaction to killed or dying bacteria (e.g. erythema nodosum leprosum [a type of antigen-antibody complex deposition panniculitis] and reversal reaction [upgrading cell-mediated immune response]):
  - symptomatic management with NSAIDs if mild
  - prednisone with 12-24 wk taper if severe
  - thalidomide for erythema nodosum leprosum

Prognosis
- curable with WHO approved treatment regimens
- complications: muscle atrophy, contractures, blindness, trauma/superinfection of lesions, crippling/loss of digits and limbs, erythema nodosum leprosum, social stigmatization due to clofazimine hyperpigmentation
- long post-treatment follow-up warranted to monitor for relapse and immune

Lyme Disease

Etiology/Epidemiology
- spirochete bacteria: *Borrelia burgdorferi* (North America), *B. garinii, B. afzelii* (Europe and Asia)
- transmitted by *Ixodes* tick
- reported in 49 of the 50 U.S. states, but most cases occur in the Northeast, the Midwest, and Northern California
- as a result of climate change, Lyme disease has spread into higher latitudes. In Canada, reported in southern and southeastern Quebec, southern and eastern Ontario, southeastern Manitoba, New Brunswick, and Nova Scotia, as well as southern British Columbia
- small rodents (mice) serve as primary reservoir, while larger animals (white-tailed deer) serve as hosts for ticks
- human contact usually May-August in fields with low brush near wooded areas, but may start earlier in the spring or later in the fall as a result of warmer winters due to climate change
- infection usually requires >36 h tick attachment
- as a result of climate change, other tick-borne diseases are expected to increase in prevalence: Anaplasmosis, Babesiosis, Powassan virus, and B. miyamotoi disease

BAKE a Key Lyme Pie
Bell's palsy
Arthritis
Kardiac block
Lyme
Erythema chronicum migrans

Clinical Features
- stage 1 (early localized stage: 7-14 d post-bite)
  - malaise, fatigue, headache, myalgias
  - erythema migrans: expanding, non-pruritic bulls-eye (target) lesions (red with clear centre) at site of tick bite
- stage 2 (early disseminated stage: weeks post-infection)
  - CNS: aseptic meningitis, CN palsies (CN VII palsy), peripheral neuritis
  - cardiac: heart block or myocarditis
- stage 3 (late persistent stage: months to years post-infection)
  - may not have preceding history of early-stage infection
  - MSK: chronic monoarticular or oligoarticular arthritis
  - acrodermatitis chronicum atrophicans (due to B. afzelii)
  - neurologic: encephalopathy, meningitis, neuropathy

Investigations
- order Public-Health-Lab-approved Lyme disease testing and interpret results on basis of symptoms
- a negative test for Lyme disease does not preclude a tick-borne disease; further testing may be indicated if symptoms are present

Prevention
- early identification, investigation of symptoms, and reporting of tick-borne illnesses
- use of protective clothing (tuck pants into socks), insect repellent, inspection for ticks, and prompt removal of tick
- doxycycline single dose prophylaxis within 72 h of removal of an engorged Ixodes scapularis tick in hyperendemic area (local rate of infection of ticks ≥20%) for patients >8 yr who are not pregnant or lactating

Treatment
- stage 1: doxycycline/amoxicillin/cefuroxime
- stage 2-3: ceftriaxone or doxycycline

Toxic Shock Syndrome

Etiology
- superantigens produced by some strains of *S. aureus* or GAS cause widespread T-cell activation and pro-inflammatory cytokine release (IL-1, IL-6, TNF)
- course of disease is precipitous and leads to acute fever, shock, multiorgan failure
- staphylococcal Toxic Shock Syndrome (TSS) involves the production of superantigen toxic shock syndrome toxin 1 (TSST-1)
- streptococcal TSS involves the production of superantigens SPEA, SPEB, SPE

Risk Factors
- staphylococcal: tampon use, nasal packing, wound infections (e.g. postpartum vaginal or cesarean or surgical infections)
- streptococcal: minor trauma, surgical procedures, preceding viral illness (e.g. chickenpox), use of NSAIDs

Clinical Features and Investigations
- acute onset
- staphylococcal TSS
  - T >38.9°C
  - sBP ≤90 mmHg
  - diffuse erythroderma with subsequent desquamation, especially on palms and soles
  - involvement of 3 or more organ systems: GI (vomiting, diarrhea), muscular (myalgia, increased CK), mucous membranes (hyperemia), renal, hepatic, hematologic (thrombocytopenia), CNS (disorientation)
  - isolation of *S. aureus* is not required for diagnosis (*S. aureus* is rarely recovered from blood in TSS)
- streptococcal TSS
  - sBP ≤90 mmHg
  - isolation of GAS from a normally sterile site (e.g. blood, pleural, tissue biopsy, or surgical wound)
  - ≥2 of coagulopathy, liver involvement, ARDS, soft tissue necrosis (necrotizing fasciitis, myositis, gangrene), renal impairment, erythematous macular rash that may desquamate

Treatment
- supportive care, fluid resuscitation, surgical debridement of infected tissue
- streptococcal: IV penicillin and clindamycin ± IVIG
- staphylococcal: for methicillin-susceptible *S. aureus*: clindamycin + cloxacillin (IV); for MRSA: clindamycin + vancomycin x 10-14 d

Cat Scratch Disease

Etiology
- *Bartonella henselae*: intracellular bacteria
- cat-to-human transmission via cat scratch/bite

Clinical Features
- skin lesion appears 30 d post-inoculation
- may be followed by fever, malaise, tender regional lymphadenopathy
- usually self-limited
- in some patients, organism may disseminate causing FUO, hepatosplenomegaly, retinitis, encephalopathy, infective endocarditis, uveitis
- in patients with advanced HIV, can present with violacious nodular skin lesions + underlying bone involvement, known as "bacilliary angiomatosis"

Investigations
- serology, PCR, lymph node biopsy

Treatment
- the disease may be self-limited but treatment is recommended by the Infectious Disease Society of America with a 5 d course of azithromycin for immunocompetent patients with mild to moderate illness
- needle aspiration of painful suppurative lymph nodes may hasten the relief of symptoms
- combination therapy consisting of doxycycline or azithromycin plus rifampin often used for disseminated disease (neuroretinitis, hepatosplenic involvement)

Rocky Mountain Spotted Fever

Etiology
- Rickettsia rickettsii: obligate intracellular GN organism
- reservoir hosts: rodents, dogs
- vectors: *Dermacentor* ticks in North America; *Rhipicephalus* ticks in Mexico and Central America
- organisms cause inflammation of endothelial lining of small blood vessels, leading to small hemorrhages and thrombi
- can cause widespread vasculitis leading to headache, and CNS changes; can progress to death if treatment is delayed

Clinical Features
- usually occurs in summer following tick bite
- influenza-like prodrome: acute onset fever, headache, myalgia, nausea/vomiting, anorexia
- macular rash appearing on d 2-4 of fever
  - begins on wrists and ankles, then spreads centrally to arms/legs/trunk/palms/soles
  - occasionally "spotless" (10% of patients)

Investigations
- skin biopsy and serology (indirect fluorescent antibody test)

Treatment
- empiric doxycycline, usually 5-7 d (treat for 3 d after defervescence)

West Nile Virus

Epidemiology
- virus has been detected throughout the United States and much of southern Canada (Quebec, Ontario, Manitoba, Saskatechewan, Alberta)
- case-fatality rates in severe cases are ~10%

Transmission
- primarily from mosquitoes that have fed on infected birds (crows, blue jays)
- transplacental, blood products (rare), organ transplantation
- rising temperatures linked to increased mosquito survival and geographical range, increased biting rates, increased replication of virus within mosquitoes, shorter reproduction rates, and longer transmission seasons. Climate change also affects bird migration patterns and timing, causing changes in virus spread

Clinical Features
- 80% are asymptomatic
- most symptomatic cases are mild (West Nile fever): acute onset of headache, back pain, myalgia, anorexia, maculopapular non-pruritic rash involving chest, back, arms
- severe complications: encephalitis, meningoencephalitis, and acute flaccid paralysis (especially in those >60 yr)

Investigations
- IgM antibody in serum or CSF is the best test (cross reactivity with yellow fever and Japanese encephalitis vaccines, and with dengue fever and St. Louis virus infection); may not reflect current illness as IgM antibody can last for >6 mo
- viral isolation by PCR from CSF, tissue, blood, and fluids (all have low sensitivity due to transient viremia)
- CSF: elevated lymphocytes and protein if CNS involvement

Treatment and Prevention
- treatment: supportive
- prevention: mosquito repellant (DEET, picaridin), drain stagnant water, community mosquito control programs

Syphilis

Etiology
- *Treponema pallidum*: thick motile spirochetes historically detectable by dark-field microscopy
- transmitted sexually, vertically, or parenterally (rare)

Clinical Features
- see Dermatology, D38 and Gynecology, GY30
- multi-stage disease
  1. primary syphilis (3-90 d post-infection)
     - painless chancre at inoculation site (any mucosal surface)
     - regional lymphadenopathy
     - acute disease lasts 3-6 wk, 25% progress to secondary syphilis without treatment
  2. secondary syphilis = systemic infection (2-8 wk following chancre)
     - maculopapular non-pruritic rash including palms and soles
     - generalized lymphadenopathy, fever, malaise, headache, aseptic meningitis, ocular/otic syphilis
     - condylomata lata: painless, wart-like lesion on palate, vulva, or scrotum (highly infectious)
  3. latent syphilis
     - asymptomatic infection that follows untreated primary/secondary syphilis
     - early latent (<1 yr post-infection) or late latent/unknown duration (>1 yr post-infection)
     - increased transmission risk with early latent; longer treatment duration required for late latent
  4. tertiary syphilis (1-30 yr post-infection)
     - gummatous syphilis: nodular granulomas of skin, bone, liver, testes, brain
     - aortic aneurysm and aortic insufficiency
  5. congenital syphilis
     - causes spontaneous abortions, stillbirths, congenital malformations, developmental delay, deafness
     - most infected newborns are asymptomatic
     - clinical manifestations in early infancy include rhinitis (snuffles), lymphadenopathy, hepatosplenomegaly, pseudoparalysis (bone pain associated with osteitis), and rash (usually maculopapular and involving palms and soles)

Argyll Robertson Pupil
Accommodates but does not react to light

Those with Untreated 1° or 2° Syphilis
1/3 Cure
1/3 Latent indefinitely
1/3 3° syphilis

Causes of False Positive VDRL and RPR Tests

Viruses (mononucleosis, hepatitis)
Drugs and substance misuse
Rheumatic fever
Lupus and leprosy

- late onset manifestations (>2 yr of age) include saddle nose, saber shins, Clutton joints, Hutchinson's teeth, mulberry molars, rhagades, CN VIII deafness, interstitial keratitis, juvenile paresis

6. neurosyphilis
   - headache, dementia, difficulty in coordination, paralysis, sensory deficits, personality changes, Argyll-Robertson pupils, tabes dorsalis
   - can occur from secondary stage onward

Patients with 2° or 3° syphilis treated with penicillin may experience a Jarisch-Herxheimer reaction. Lysis of organisms releases pyrogens thought to cause fever, chills, myalgia, and flu-like symptoms that may last up to 24 h

Investigations

- syphilis tests are conducted by Public Health labs. Thus, order set for syphilis is simplified and does not require specification of which test to complete. Below are details on what tests are conducted at the Public Health lab
- initial screening tests: traditionally non-treponemal tests (RPR, VRDL), or treponemal tests in some jurisdictions (EIA, CMIA, CLIA)
- confirmatory tests: treponemal tests (TPPA, FTA-ABS, MHA-TP, TPI)
- LP for neurosyphilis if: seropositive and symptoms of neurosyphilis or treatment failure/other tertiary symptoms, or with HIV and late latent/unknown duration syphilis; consider in others
- for congenital syphilis, LP is essential; long bone x-rays may also be helpful

VDRL Venereal Disease Research Laboratory
RPR Rapid Plasma Reagin
EIA Enzyme Immunoassay
CLIA ChemiLuminescent ImmunoAssay
CMIA ChemiLuminescent Microparticle ImmunoAssay
FTA-ABS Fluorescent Treponema Antibody-Absorption
MHA-TP Microhemagglutination Assay *T. pallidum*
TPPA *T. pallidum* Particle Agglutination Assay
TPI *T. pallidum* immobilization test

Treatment

- for 1°, 2°, early latent: benzathine penicillin G 2.4 million units IM x 1
- for 3°, late latent: benzathine penicillin G 2.4 million units IM weekly x 3
- if truly allergic to penicillin: doxycycline 100 mg PO BID x 14 d is a second line therapy (x 28 d in late disease)
- for pregnant patients allergic to penicillin, oral desensitization techniques are considered safe
- neurosyphilis: aqueous penicillin G 16-24 million units/d IV x 14 d ± single dose of benzathine penicillin
- for congenital syphilis, penicillin G IV x 10 d
- see Family Medicine, FM47 for generalized STI workup

Tuberculosis

Etiology, Epidemiology, and Natural History

- 1/3 of the world's population is infected with TB
- contracted by aerosolized inhalation of *Mycobacterium tuberculosis*, a slow growing aerobe (doubling time = 18 h) that can evade innate host defenses, survive, and replicate in macrophages
- inhalation and deposition in the lung can lead to one of the following outcomes:
  1. immediate clearance of the pathogen
  2. latent TB: asymptomatic infection contained by host immune defenses (represents 90% of infected people)
  3. primary TB: symptomatic, active disease (represents 5% of infected people)
  4. secondary TB: symptomatic reactivation of previously dormant TB (represents 5-10% of those with latent TB, most often within the first 1-2 yr of initial infection) at a pulmonary or extra-pulmonary site

Tuberculous Polyserositis
Pleural + pericardial + peritoneal effusions (usually from granuloma breakdown that spills TB into pleural cavity – very rare)

Risk Factors

- social and environmental factors
  - birth in or extended travel to a country with high TB prevalence (e.g. Asia, Latin America, Sub-Saharan Africa, Eastern Europe)
  - the incidence of TB is 25 times higher in Canadian-born Indigenous peoples (highest in Inuit) compared to Canadian-born non-Indigenous peoples
  - personal/occupational contact, crowded living conditions, low socioeconomic status (SES), people experiencing homelessness, IDU
- host factors
  - immunocompromised (especially HIV), including extremes of age
  - immunosuppressed (TNF-α inhibitors, glucocorticoids)
  - silicosis
  - chronic kidney disease requiring dialysis
  - diabetes
  - malignancy and chemotherapy
  - substance use (e.g. drug use, alcohol use disorder, smoking)

Clinical Features

- primary infection usually asymptomatic, although progressive primary disease may occur, especially in children and immunosuppressed patients
- secondary infection/reactivation usually produces constitutional symptoms (fatigue, anorexia, night sweats, weight loss) and site-dependent symptoms
  1. pulmonary TB
     - chronic productive cough + hemoptysis, fever, night sweats, weight loss, chest pain, anorexia
     - CXR consolidation or cavitation, lymphadenopathy, predominantly upper lung findings but variable
     - non-resolving pneumonia despite standard antimicrobial therapy
  2. miliary TB
     - widely disseminated spread especially to lungs, abdominal organs, marrow, CNS
     - CXR: multiple small 1-5 mm millet seed-like lesions throughout lung

3. extra-pulmonary TB
    - can occur in any organ - lymphadenitis, pleurisy, pericarditis, hepatitis, peritonitis, meningitis, osteomyelitis (vertebral = Pott disease), adrenal (causing Addison disease), renal, ovarian

Investigations

- screening for latent TB may be done via TST or IFN-γ release assay (IGRA)
    - both can be used to diagnose prior TB infection. IGRA has fewer false positives as it does not detect antigens in BCG vaccine or most types of non-tuberculosis mycobacteria
        - neither should be used in adults for active TB diagnosis or monitoring anti-TB treatment response
        - TST preferred when repeat testing planned to assess risk of new infection (e.g. serial testing in healthcare)
- IGRA preferred when BCG vaccine after 1 y/o, vaccination more than once, or unable to return for reading
- diagnostic tests/investigations for active pulmonary TB
    - sputum specimens (either spontaneous or induced) should be collected for AFB smear and culture; the three specimens can be collected on the same day, a minimum of 1 h apart
    - BAL if other lung pathology (e.g. lung cancer) also suspected, or TB suspected despite negative sputum samples
    - CXR
        - classic triad: apical-posterior infiltrates, lung volume loss, cavitation
        - atypical features: hilar/mediastinal lymphadenopathy, non-cavitary infiltrates
        - signs of complications: endobronchial spread, pleural effusion, pneumothorax
        - Ghon complex: a parenchymal granuloma, indicating a previous tuberculosis infection, and a calcified hilar lymph node on the same side

Positive TST Test
If induration at 48-72 h
>5 mm if immunocompromised, close contact with active TB
>10 mm all others; positive PPD; CXR; decision to treat depends on individual risk factors
False(–): poor technique, anergy, immunosuppression, infection <10 wk or remotely
False(+): BCG after 12 mo of age in a low-risk individual, nontuberculous mycobacterial **(NTM)**
Booster effect: initially false(–) result boost to a true(+) result by the testing procedure itself (usually if patient was infected long ago so had diminished delayed type hypersensitivity reaction or if history of BCG)

Prevention

- primary prevention
    - airborne isolation for active pulmonary disease
    - BCG vaccine
        - ~80% effective against paediatric miliary and meningeal TB
        - effectiveness in adults debated (anywhere from 0-80%)
        - recommended in high-incidence communities in Canada for infants in whom there is no evidence of HIV infection of immunodeficiency; widely used in other countries
- prevention of reactivation of latent infection
    - rifampin (RIF) (10 mg/kg (600 mg maximum)) daily for 4 mo (active disease must be ruled out)
    - isoniazid (INH) (15 mg/kg (900 mg maximum)) + pyridoxine (B6) and rifapentine (RPT) (dose by weight) weekly for 3 mo
    - INH (5 mg/kg (300 mg maximum)) + pyridoxine (B6) daily for 9 mo (previous standard regimen, recommended when rifamycin regimens cannot be used)
    - INH (5 mg/kg (300 mg maximum)) + pyridoxine (B6) daily for 6 mo
    - INH (5 mg/kg (300 mg maximum)) + pyridoxine (B6) and RIF (10 mg/kg (600 mg maximum)) daily for 3 mo

TB Treatment

RIPE
Rifampin
INH
Pyrazinamide
Ethambutol

Treatment of Active Infection

- given the nuances of TB treatment, active TB infection should be managed by an experienced TB clinician

pulmonary TB: INH + rifampin + pyrazinamide + ethambutol x 2 mo (initiation phase), then INH + rifampin x 4 mo in fully susceptible TB (continuation phase), total 6 mo. Extend continuation phase to 7 mo if >65 y/o, pregnant, or risk of hepatotoxicity

- extrapulmonary TB: same regimen as pulmonary TB but increase to 12 mo in bone/joint, CNS, and miliary/disseminated TB + corticosteroids for meningitis, pericarditis
- for patients taking INH, pyridoxine should be added in cases of diabetes, renal failure, malnutrition, substance use disorders, seizure disorders, pregnancy/breastfeeding, risk of neuropathy
- empiric treatment of suspected MDR or extensively drug-resistant (XDR) TB requires referral to a specialist
    - MDR = resistance to INH and rifampin ± others
    - XDR = resistance to INH + rifampin + fluoroquinolone + >1 of injectable, second-line agents
        - very difficult to treat, global public health threat, 5 documented cases in Canada from 1997-2008
    - suspect MDR TB if previous treatment failed, exposure to known MDR index case, or immigration from a high-risk area
- note: TB is a reportable disease to Public Health (please see Public Health Agency of Canada website for more information)

HIV and AIDS

Epidemiology

Canadian Situation (Public Health Agency of Canada, 2016)
- estimated 65040 Canadians living with HIV infection at the end of 2016, 20% unaware of HIV-positive status
- 2090 new infections were reported in 2013: MSM account for 53% of cases, people who inject drugs (PWID) 19%%

Global Situation (WHO and UNAIDS Core Epidemiology Slides, July 2018)
- estimated 36.7 million people living with HIV/AIDS at the end of 2016
- estimated 1.8 million newly infected in 2016
- estimated 1 million AIDS-related deaths in 2016

Etiology

- HIV is a retrovirus that causes progressive immune system dysfunction, predisposing patients to various opportunistic infections and malignancies
- HIV virion includes an envelope (gp41 and gp120 glycoproteins), matrix (p17), and capsid (p24), enclosing 2 single-stranded copies of RNA plus enzymes in its core
- virion glycoproteins bind CD4 and CCR5/CXCR4 on CD4+ T lymphocytes (T-helper cells) to fuse and enter the cells
- RNA converted to dsDNA by viral reverse transcriptase; dsDNA is integrated into host genome by viral integrase
- virus DNA transcribed and translated using host cell machinery, post-translational modifications include proteolytic activity of virally encoded protease enzymes
- newly produced virions bud out of host cell, incorporating host cell membrane; additional maturation steps are required before virion is considered infectious
- exact mechanisms of CD4 depletion incompletely characterized but likely include direct viral cytopathic effects, apoptosis, and increased cell turnover

Modes of Transmission

Table 20. Modes of Transmission in Adolescents and Adults by Site and Medium

HIV Invasion Site	Sub-Location	Transmission Medium	Transmission Probability per Exposure Event
Female genital tract	Vagina, ectocervix, endocervix	Semen	1 in 200 to 1 in 2000
Male genital tract	Inner foreskin, penile urethra	Cervicovaginal and rectal secretions and desquamations	1 in 700 to 1 in 3000
Intestinal tract	Rectum	Semen	1 in 20 to 1 in 300
	Upper GI tract	Semen	1 in 2500
		Maternal blood/genital secretions (intrapartum)	1 in 5 to 1 in 10
		Breastmilk	1 in 5 to 1 in 10
Placenta	Chorionic villi	Maternal blood (intrauterine)	1 in 10 to 1 in 20
Blood stream		Contaminated blood products	95 in 100 to 1 in 150
		Sharp/needlestick injuries	

Adapted with permission from Macmillan Publishers Ltd., Hladik F, McElrath MJ. Setting the stage: host invasion by HIV. Nat Rev Immunol 2008;8:447-457.
NOTE: these estimates are for "all comers" i.e. they estimate transmission risk for anyone with HIV infection and do not take into account treatment status of the HIV+ person (in contrast to results of PARTNER study)

p24 = capsid protein
gp41 = fusion and entry
gp120 = attachment to host T-cell

Homozygosity for A32 mutation in CCR5 gene confers relative resistance to HIV infection
Heterozygosity for A32 mutation in CCR5 gene associated with slower disease course

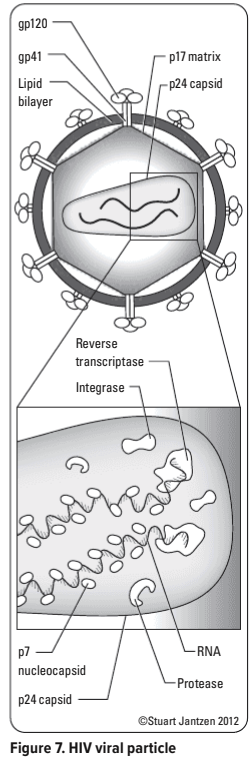

Figure 7. HIV viral particle

Natural History

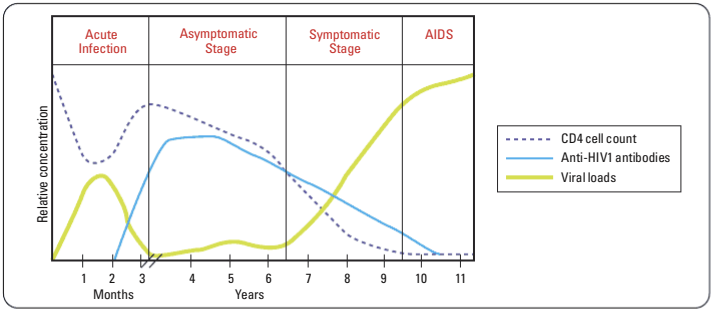

Figure 8. Relationships between CD4 T-cell count, viral load, and anti-HIV1 antibodies

Acute (Infection) Retroviral Syndrome

- 40-90% experience an acute non-specific illness (may include fever, pharyngitis, lymphadenopathy, rash, arthralgias, myalgias, headache, GI symptoms, oral ulcers, weight loss) 2-6 wk post-exposure lasting 10-15 d
- hematologic disturbances (lymphopenia, thrombocytopenia)
- 10-20% present with aseptic meningitis, CN palsies, or other neurological presentations; HIV RNA and/or p24 may be detected in CSF
- associated with a high level of plasma viremia and therefore high-risk of transmission

Asymptomatic (Latent) Stage

- during latent phase, HIV infects and replicates in CD4+ T lymphocytes (lymph nodes)
- normal CD4 count in adults: 500-1100 cells/mm ^{3}
- CD4 count drops 60-100 cells/mm ^{3}per yr but is variable
- by 10 yr post-infection, 50% have advanced HIV (i.e. AIDS), 30% demonstrate milder symptoms, and <20% are asymptomatic if untreated

Definition of AIDS

- HIV-positive AND one or more of the clinical illnesses that characterize AIDS, including: opportunistic infections (e.g. Pneumocystis jiroveci pneumonia (PJP, previously PCP), esophageal candidiasis, CMV, Mycobacterium avium complex (MAC), TB, toxoplasmosis), malignancy (Kaposi's sarcoma, invasive cervical cancer), wasting syndrome OR CD4 <200 (or <15%); this is largely historical because ART can reverse CD4 count decline

Table 21. Symptomatic Stage (CD4 count thresholds for classic clinical manifestations)

CD4 Counts	Possible Manifestations
<500 cells/mm^3	Often asymptomatic Constitutional symptoms: fever, night sweats, fatigue, weight loss Mucocutaneous lesions: seborrheic dermatitis, HSV, VZV (shingles), oral hairy leukoplakia (EBV), candidiasis (oral, esophageal, vaginal), KS Recurrent bacterial infections, especially pneumonia Pulmonary and extrapulmonary tuberculosis Lymphoma
<200 cells/mm^3	*Pneumocystis jiroveci* pneumonia (formerly PCP) KS Oral thrush Local and/or disseminated fungal infections: *Cryptococcus neoformans, Coccidioides immitis, Histoplasma capsulatum*
<100 cells/mm^3	Progressive multifocal leukoencephalopathy (PML) – JC virus CNS toxoplasmosis
<50 cells/mm^3	CMV infection: retinitis, colitis, cholangiopathy, CNS disease MAC Bacillary angiomatosis (disseminated *Bartonella*) Primary CNS lymphoma (PCNSL)

Laboratory Diagnosis

- anti-HIV antibodies detectable after a median of 3 wk, virtually all by 3 mo (therefore 3 mo window period)
- initial screening test (3rd generation antibody test): ELISA detects serum antibody to HIV; sensitivity >99.5%
- increasingly, combination p24 antigen/HIV antibody tests (4th generation) used for screening; improved sensitivity in early or acute infection and sensitivity/specificity approach 100% for chronic infection
- confirmatory test: if positive screen, Western blot confirmation by detection of antibodies to at least two different HIV protein bands (p24, gp41, gp120/160); specificity >99.99%

Sexual Activity without Condoms and Risk of HIV Transmission in Serodifferent Couples when the HIV-Positive Partner is using Suppressive Antiretroviral Therapy
JAMA 2016;316(2):171-181
Purpose: To evaluate the rate of within-couple HIV transmission (heterosexual and MSM) during periods of sex without condoms and when the HIV+ partner had HIV-1 RNA <200 copies/mL.
Methods: Prospective, observational PARTNER study, enrolled 1166 HIV serodifferent couples (in which the HIV+ partner was taking ART) who reported having condomless sex. Primary outcome was risk of within-couple HIV transmission to HIV- partner.
Results: Enrolled couples provided 1238 eligible couple-years of follow-up. Couples reported condomless sex for a median of 2 yr and condomless sex with other partners was reported by 108 HIV- MSM and 21 heterosexuals. While 11 HIV- partners became HIV+ (10 MSM; 1 heterosexual), no phylogenetically linked transmissions occurred over eligible couple-years of follow-up (within-couple HIV transmission = 0, 95% CI 0.30-0.71 per 100 couple-years).
Conclusions: Among serodifferent heterosexual and MSM couples in which HIV+ partner was using ART and who reported condomless sex, during median 1.3 yr/couple follow-up, there were no documented cases of within-couple transmission.

Seroconversion: Development of detectable anti-HIV antibodies

Window Period: Time between infection and development of anti-HIV antibodies; when serologic tests (ELISA, Western blot) are negative

All infants born to HIV-infected mothers have positive enzyme linked immunosorbent assay (ELISA) tests because of circulating maternal anti-HIV antibodies, which disappear by 18 mo; early diagnosis is made by detection of HIV RNA in plasma

HLA-B*5701 Testing
Abacavir hypersensitivity reactions usually only occur in individuals carrying this HLA allele (~5-7% of White individuals, lower prevalence in other ethnic groups)
Routine screening for HLA-B*5701 at baseline and definitely prior to abacavir use

HIV Status
CD4 count: progress and stage of disease
Viral load: rate of progression

HIV Non-disclosure Laws in Ontario
In 2017, Ontario changed HIV non-disclosure laws for people living with HIV, where non-disclosure of HIV status to a sexual partner is no longer considered a criminal offense if one of the following criteria is met:

- On antiretroviral therapy with a viral load <200 copies/mL for at least 6 mo
- Viral load between 200-1500 copies/mL and a condom is used properly and does not break

- rapid (point-of-care) antibody tests: higher false positives, therefore need to confirm positive results with traditional serology
- p24 antigen: detection by ELISA may be positive during "window period"

Management of the HIV-Positive Patient

- verify positive HIV test
- complete baseline history and physical exam, then follow-up every 3-6 mo
- laboratory evaluation
  - if non-stable and non-suppressed viral load, order routine CD4 count to measure status of the immune system
  - routine HIV-RNA levels (viral load) also important indicator of effect of ART
  - baseline HIV resistance testing to guide ARV therapy
  - HLA-B*5701 genetic test to screen for abacavir hypersensitivity if considering abacavir in treatment regimen
  - CCR5 tropism testing if considering CCR5 antagonist in treatment regimen
  - baseline tuberculin skin test (PPD): induration greater than 5 mm is positive
  - baseline serologies (hepatitis A, B, and C, syphilis, toxoplasmosis, CMV, VZV)
  - routine biochemistry and hematology, CXR, urinalysis
  - annual fasting lipid profile and fasting glucose (due to ART side effects)
- education
  - regular follow-up on viral loads (q3-6 mo) as well as strict adherence to ART improves prognosis; routine monitoring of CD4 counts until consistently over 500 cells/mm^{3}with suppressed viral load
  - prevention of further transmission through safer sex and clean needles for IDU
  - HIV superinfection (transmission of different HIV strains from another HIV+ person) can rarely occur so barrier protection during sex is still recommended
  - discuss importance of disclosing HIV status to partners including risk of criminal prosecution of non-disclosure in jurisdictions where applicable
  - connect to relevant community groups and resources
- health care maintenance
  - assessment of psychosocial concerns and referral to psychiatry or social work if appropriate
  - vaccines: influenza annually, 23-valent pneumococcal every 5 yr, HBV (if not immune), HAV (if seronegative), HPV
  - annual screening (PAP smear), regular STI screening
  - management of comorbid conditions and provision of general primary care

Table 22. Prophylaxis Against Opportunistic Infections in HIV-infected Patients

Pathogen	Indication for Prophylaxis	Preferred Prophylactic Regimen
Pneumocystis jirovecii	CD4 count <200 cells/mm^3	TMP/SMX 1 SS or DS once daily
Toxoplasma gondii	IgG antibody to *Toxoplasma* and CD4 count <100 cells/mm^3	TMP/SMX 1 DS once daily
Mycobacterium tuberculosis	PPD reaction >5 mm or contact with case of active TB	INH + pyridoxine daily x 9 mo
***Mycobacterium* avium complex**	CD4 count <50 cells/mm^3	No prophylaxis if patients are started on ARTs

SS = single strength; DS = double strength
See USPHS/IDSA guidelines for preventing opportunistic infections among HIV-infected persons (Relevant Sections updated 2013, 2015). Available from: http://aidsinfo.nih.gov/

Anti-Retroviral Treatment

Overall Treatment Principles

- recommended that all HIV-positive patients initiate combination ART to restore and preserve immune function, reduce morbidity, prolong survival, and prevent transmission
- patients starting ART should be committed to treatment and understand the importance of adherence; poor compliance can lead to viral resistance; may defer treatment on the basis of clinical and psychosocial factors on case-by-case basis
- consider results of baseline resistance testing and complete ART history before initiating or re-initiating ART
- goal: keep viral load below limit of detection i.e. <20 copies/mL (undetectable); viral load should decrease 10-fold within 4-8 wk, be undetectable by 6 mo, and restore immunological function
- strong evidence against intermittent ART or 'drug holidays'
- patient with undetectable viral load adhering to ART does not transmit HIV to sexual partners

ART Recommendations for Treatment of Naïve Patients

- 2 NRTIs + 1 INSTI or "boosted" PI (combined with ritonavir or cobicistat for improved pharmacokinetics)
- note: guidelines are subject to frequent change. Combination therapy is suggested, preferably with single pill regimens

Treatment Failure

- defined primarily by viral load (persistently >200 copies/mL)
- ensure that viral load >20 is not just a transient viremia or 'blip'; confirm medication adherence, assess drug interactions, perform resistance testing

1° and 2° prophylaxis may be discontinued if CD4 count is above threshold for ≥6 mo while on ART

Anti-Retroviral Pre-Exposure Prophylaxis for Preventing HIV in High-Risk Individuals
Cochrane DB Syst Rev 2012;7:CD007189
Purpose: To evaluate the efficacy of oral anti-retroviral prophylactic therapy in preventing HIV infection.
Study: Systematic review of 12 randomized controlled trials with 6 trials forming the core analysis.
Population: 9849 HIV-uninfected patients at high risk of contracting HIV including MSM, serodiscordant couples, and others.
Outcome: New infection with HIV.
Results: Daily oral tenofovir disoproxil fumarate (TDF) plus emtricitabine (FTC) reduced the risk of HIV acquisition compared to placebo (RR 0.49; 95% CI 0.28-0.85). TDF alone also showed significant risk reduction in trials with fewer patients (RR 0.33; 95% CI 0.20-0.55). There was no significant increase in adverse events in any of the treatment groups. Sexual practices and adherence did not differ between treatment and placebo arms.
Conclusions: Pre-exposure prophylaxis with TDF with or without FTC effectively reduces the risk of HIV acquisition in high-risk, HIV-uninfected patients without causing significant adverse effects.

Reasons for Deterioration of a Patient with HIV/AIDS

- Opportunistic infections
- Neoplasms
- Medication-related toxicities
- Co-infections (e.g. HBV, HCV, STIs)
- Non-AIDS-related comorbidities (e.g. cardiovascular, renal, hepatic, neurocognitive, bone disease)

Treatment Failure

- Assess adherence
- Assess drug interactions
- Resistance testing
- Rule out opportunistic infections
- Rule out marrow suppression
- Construct new combination drug regimen

Table 23. Anti-Retroviral Drugs

Class	Drugs	Mechanism	Adverse Effects
Nucleoside reverse transcriptase inhibitors (NRTIs)	abacavir (ABC) emtricitabine (FTC) lamivudine (3TC) tenofovir disoproxil fumarate (TDF) tenofovir alafenamide (TAF) zidovudine (AZT) didanosine (ddI) stavudine (d4T) **Combination Tablets:** AZT/3TC (Combivir®) AZT/3TC/ABC (Trizivir®) ABC/3TC (Kivexa®) TDF/FTC (Truvada®) TAF/FTC (Descovy®)	Incorporated into the growing viral DNA chain, thereby competitively inhibiting reverse transcriptase and terminating viral DNA growth	Lactic acidosis (often secondary to mitochondrial toxicity) Lipodystrophy Rash Nausea/vomiting/diarrhea Bone marrow suppression (AZT) Peripheral neuropathy (ddI, d4T) Drug-induced hypersensitivity (ABC) Pancreatitis (ddI/d4T) Myopathy (AZT)
Non-nucleoside reverse transcriptase inhibitors (NNRTIs)	delavirdine (DLV) doravirine (DOR) efavirenz (EFZ) etravirine (ETR) nevirapine (NVP) rilpivirine (RPV)	Non-competitively inhibit function of reverse transcriptase, thereby preventing viral RNA replication	Rash, Stevens-Johnson syndrome CNS: dizziness, insomnia, somnolence, abnormal dreams (EFZ) Hepatotoxicity (NVP – avoid in females with CD4 >250, men with CD4 >400) CYP3A4 interactions
Protease inhibitors (PIs)*	atazanavir (ATV) amprenavir (APV) darunavir (DRV) darunavir/cobicistat (DRV/c) lopinavir/ritonavir (LPV/r) nelfinavir (NFV) ritonavir (RTV) tipranavir (TPV) indinavir	Prevent maturation of infectious virions by inhibiting the cleavage of polyproteins	Lipodystrophy, metabolic syndrome Nausea/vomiting/diarrhea Nephrolithiasis (indinavir) Rash (APV) Hyperbilirubinemia (ATV, indinavir) CYP3A4 interactions Hyperlipidemia
Integrase strand transfer inhibitors (INSTIs)	bictegravir cabotegravir dolutegravir (DTG) elvitegravir (EVG) raltegravir (RAL)	Inhibits integration of HIV DNA into the human genome thus preventing HIV replication	
Fusion inhibitor (only used if resistance)	enfuvirtide (T-20)	Inhibit viral fusion with T-cells by inhibiting gp41, preventing cell infection	Injection site reactions, rash, infection, diarrhea, nausea, fatigue
CCR5 antagonist	maraviroc (MVC)	Inhibit viral entry by blocking host CCR5 co-receptor	Fever, cough, dizziness

*Standard of care is to pharmacologically boost most PIs with ritonavir to increase concentrations

Lactic Acidosis

Occurs secondary to mitochondrial toxicity

Symptoms include abdominal pain, fatigue, nausea/vomiting, muscle weakness

Lipodystrophy

Body fat redistribution (mainly with old ARVs)

Lipohypertrophy (e.g. dorsal fat pad, breast enlargement, increased abdominal girth) thought to be caused primarily by protease inhibitors

Lipoatrophy (e.g. facial thinning, decreased adipose tissue in the extremities) is thought to be caused by thymidine analogue NRTIs such as d4T and AZT

Metabolic abnormalities: lipids (increased LDL, increased TGs), glucose (insulin resistance, T2DM), increased risk of CVD

Single Tablet ART Regimens

- reduces pill burden and increases adherence
- generally better tolerated

Table 24. Single Tablet ART Regimens

Name	Contents	Common Side Effects
Biktarvy®	bictegravir/emtricitabine/tenofovir alafenamide	good side effect profile
Genvoya®	tenofovir/emtricitabine/elvitegravir/cobicistat	good side effect profile
Complera®	rilpivirine/emtricitabine/tenofovir	good side effect profile
Odefsey®	rilpivirine/emtricitabine/tenofovir alafenamide	good side effect profile
Stribild®	elvitegravir/cobicistat/emtricitabine/tenofovir	good side effect profile
Triumeq®	dolutegravir/abacavir/lamivudine	good side effect profile; use only in HLAB*5701 negative patients
Atripla®	efavirenz/tenofovir/emtricitabine	psychiatric events, vivid dreams

Recommended ARV Regimens for Treatment-Naïve HIV-infected Adults

- initial regimens for treatment (most include an integrase inhibitor and a pair of NRTIs):
  1. bictegravir/TAF/FTC
  2. DTG/ABC/3TC (in patients confirmed to be HLB*5701 negative)
  3. DTG + (TAF or TDF)/(FTC or 3TC)
  4. raltegravir + TAF (or TDF)/FTC
  5. DTG/3TC
- note: not all regimens are available in all regions

Recommended ARV Regimens for Individuals of Childbearing Potential

- there is an increased risk of neural tube defects in infants born to women on dolutegravir at time of conception
- it is not known if other INSTIs also increase risk of neural tube defects
- therefore, before beginning an INSTI-containing treatment regimen in individuals of childbearing potential, the following should be considered:
  - completing a pregnancy test
  - a discussion on risks and benefits of dolutegravir, and lack of information on other INSTIs
  - for individuals attempting to conceive: RAL + TDF/FTC, TDF/3TC, or ABC/3TC are preferred regimens; DTG regimens to be used as an alternative only
  - for individuals not attempting to conceive but are sexually active and not using contraception, consider effectiveness/tolerability, patient preferences in decision
  - for individuals using effective contraception, treatment approach is similar to that of individuals in the general population with HIV

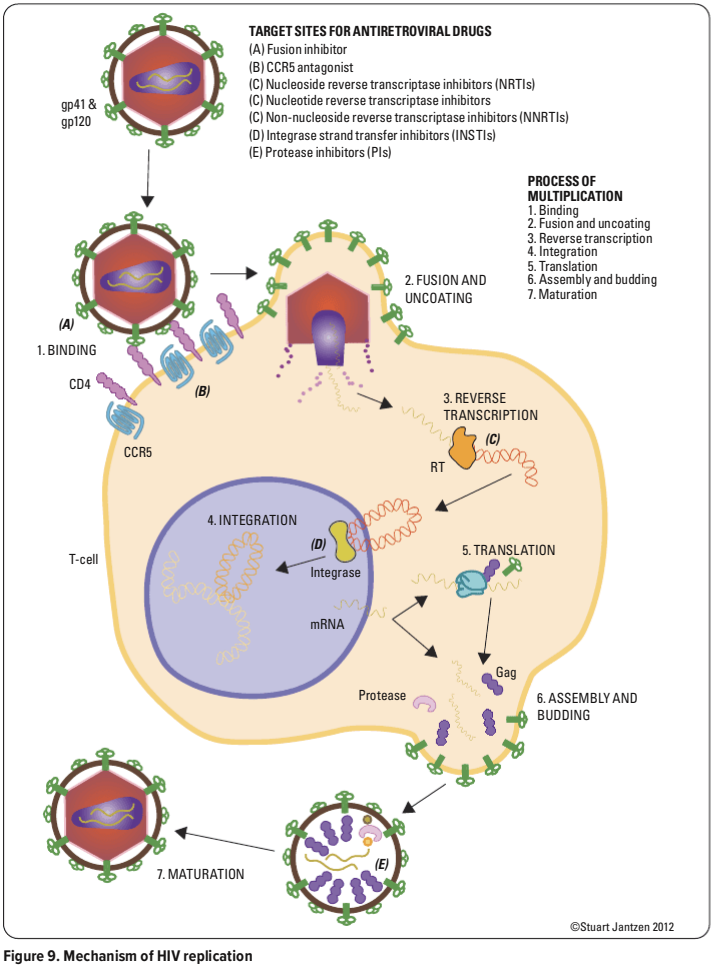

Figure 9. Mechanism of HIV replication

Prevention of HIV Infection

- education, including harm reduction
  - safer sexual practices: condoms for vaginal and anal sex, barriers for oral sex
  - harm reduction for IVDU: avoid sharing needles
- prevention of vertical HIV infection: treatment with ART should be initiated prior to pregnancy or as early as possible during pregnancy. The risk of vertical HIV transmission can be reduced to <1% if maternal ART is started in a timely manner and the maternal viral load is undetectable prior to delivery
- universal blood and body precautions for healthcare workers
  - post-exposure prophylaxis (PEP) after occupational (e.g. needle-stick injury) and non-occupational (e.g. consensual sex, sexual assault) exposure to HIV: 2- or 3-drug regimen initiated immediately (<72 h) after exposure and continuing for 4 wk
- recent data has demonstrated efficacy of pre-exposure prophylaxis (oral PrEP or topical microbicides) in preventing HIV
  - PrEP strategies include daily TDF/FTC or TAF/FTC and "PrEP on demand", where medication is taken as a double dose 12-24 h before anticipated exposure and then for 2 more doses 24 and 48 h later (i.e. 2-1-1 dosing)
- ART associated with 96% reduction in risk of transmitting HIV to sexual partners
- screening of blood and organ donation

Early identification of HIV is essential for patients to receive the maximal benefit from ART

Efficacy, Safety, and Effect on Sexual Behaviour of On-Demand Pre-Exposure Prophylaxis for HIV in Men who have Sex with Men: An Observational Cohort Study
Lancet HIV 2017;4:402-410
Purpose: Assess the efficacy, safety, and effect of on-demand pre-exposure prophylaxis (PrEP) on sexual behaviour.
Methods: Men and transgender women who have sex with men, previously enrolled in the placebo-controlled ANRS IPERGAU trial. On demand tenofovir disoproxil fumarate (300 mg) and emtricitabine (200 mg) to be taken before and after sexual intercourse and participants assessed for incidence of HIV, PrEP adherence, safety, and sexual behaviour.
Results: HIV incidence was 0.19/100 person-years (95% CI 0.01-1.08) vs. 6.60/100 person-years (95% CI 3.60-11.05) in the placebo group, relative risk reduction of 97%. Drug-related GI events were reported in 14% of participants but were self-limiting. Participants reporting condomless sex at their last receptive anal intercourse increased from 77 to 86% at 18 mo follow-up.
Conclusions: On-demand oral PrEP is highly effective at preventing HIV infection among high-risk MSM. This represents an alternative to daily PrEP.

Use of a Vaginal Ring Containing Dapivirine for HIV-1 Prevention in Women
NEJM 2016;375:2121-2132
Purpose: To evaluate whether longer-acting methods of anti-retroviral therapy (i.e. vaginal rings) may simplify use of medications and provide HIV-1 protection.
Methods: Phase 3, randomized, double-blind, placebo-controlled trial of monthly vaginal ring containing dapivirine in women (aged 18-45) in Malawi, South Africa, Uganda, and Zimbabwe.
Results: Among 2629 women enrolled, the incidence of HIV-1 infection was 3.3/100 person-years in dapivirine group and 4.5/100 person-years in placebo group. Post hoc analysis identified higher rates of HIV-1 protection in women >21 yr (56%, 95% CI 31-71) but not among those <21 yr (-27%, 95% CI -133-31), which correlated with reduced adherence.
Conclusions: Monthly vaginal ring containing dapivirine reduced risk of HIV-1 infection among African women.

Types of Testing

1. Nominal/Name-Based HIV Testing
- person ordering the test knows the identity of the person being tested for HIV
- HIV test is ordered using the name of the person being tested
- person ordering the test is legally obligated to notify Public Health officials if test results are positive for HIV
- test result is recorded in the healthcare record of the person being tested

2. Non-Nominal/Non-Identifying HIV Testing
- similar to nominal/name-based testing on all points except:
  - HIV test is ordered using a code or the initials of the person being tested

3. Anonymous Testing
- available at specialized clinics
- person ordering the HIV test does not know the identity of the person being tested
- HIV test is carried out using a unique non-identifying code that only the person being tested for HIV knows
- test results are not recorded on the healthcare record of the person being tested
- patient identification and notification of Public Health required to gain access to ART

HIV Pre- and Post-Test Counselling

- a diagnosis of HIV can be overwhelming and is often associated with stigma and discrimination
- consider pre- and post-test counselling, regardless of the results
- goals include: assessing risk, making informed decision to be tested, education to protect themselves and others from virus exposure, where to go for more information and support
- HIV-positive individuals should be connected with local support services

FUNGAL INFECTIONS

Skin and Subcutaneous Infections

Superficial Fungal Infections

- see Dermatology, D32, D33, D37, D45 D46, and D49

Dermatophytes

- see Dermatology, D31

Subcutaneous Fungal Infections

Etiology
- subcutaneous inoculation by fungi that naturally reside in the soil, including *Sporothrix schenckii*, which usually occurs in gardeners injured by a rose thorn or splinter

Clinical Features
- causes subcutaneous nodules at the point of entry, may develop into an ulcer
- fungi may migrate up lymphatic vessels creating nodules along the way – "nodular lymphangitis"

Treatment
- oral azole
- IV amphotericin B for severe or disseminated infection

Endemic Mycoses

Etiology

- fungal infection that occurs through the inhalation of spores (from soil, bird droppings, vegetation) or inoculation injury
- thermally dimorphic organisms: mould in cold temperature (e.g. soil), and yeast at higher temperature (e.g. tissue)
- in North America, the three major endemic mycoses are: histoplasmosis, blastomycosis, and coccidioidomycosis
- NB. Previously defined regions of endemicity are expanding and can no longer be used to definitively rule out infections with specific organisms

Histoplasmosis is commonly associated with exposure to chicken coops, bird roosts, and bat caves

Clinical Features

- may be asymptomatic
- all can cause pneumonia and may disseminate hematogenously
- may reactivate or disseminate during immunocompromised states

Table 25. Endemic Mycoses

Disease	Endemic Region	Clinical Features	Investigations
Histoplasma capsulatum	Ohio and Mississippi River valleys in central USA, Ontario, Quebec; widespread	Asymptomatic (in most people) Primary pulmonary Fever, cough, chest pain, headache, myalgia, anorexia CXR (acute): pulmonary infiltrates ± hilar lymphadenopathy CXR (chronic): pulmonary infiltrates, cavitary disease Disseminated (rare) Occurs primarily in immunocompromised patients Spread to bone marrow (pancytopenia), GI tract (ulcers), lymph nodes (lymphadenitis), skin, liver, adrenals, CNS	Fungal culture, fungal stain Antigen detection (urine and serum) Serology
Blastomyces dermatitidis	States east of Mississippi River, Northern Ontario, and along the Great Lakes	May be asymptomatic Primary: acute or chronic pneumonia Fever, cough, chest pain, chills, night sweats, weight loss CXR (acute): lobar or segmental pneumonia CXR (chronic): lobar infiltrates, fibronodular interstitial disease Disseminated Spread to skin (verrucous lesions that mimic skin cancer, ulcers, subcutaneous nodules), bones (osteomyelitis, osteolytic lesions), genitourinary tract (prostatitis, epididymitis)	Sputum smear and culture Direct examination of clinical specimens for characteristic broad-based budding yeast (sputum, tissue, purulent material)
Coccidioides immitis	Deserts in southwest USA, northwest Mexico	"Valley fever": subacute fever, chills, cough, chest pain, sore throat, fatigue that lasts for wk to mo Can develop hypersensitivity with arthralgias, erythema nodosum Disseminated Rare spread to skin (ulcers), joints (synovitis), bones (lytic lesions), meninges (meningitis) Common opportunistic infection in patients with HIV	Sputum culture Direct examination of clinical specimens for characteristic yeast (sputum, tissue, purulent material)

Opportunistic Fungi

Pneumocystis jirovecii (formerly *P. carinii*) Pneumonia: PJP or PCP

Etiology

- respiratory exposure to unicellular fungus (previously classified as a protozoan)
- can be transmitted from person to person
- without prophylaxis, HIV-positive patients with a CD4 count <200 cells/mm3 have an 80% lifetime risk of PJP
- most cases of PJP occur in patients who are unaware of their HIV infection, do not seek medical care for HIV, or who do not use prophylaxis
- in HIV-negative patients, PJP occurs almost exclusively in immunocompromised patients (e.g. organ transplant patients, inflammatory conditions, hematological malignancies)

CXR in *P. jirovecii*
Bilateral, diffuse opacities
CXR may be normal (20-30% cases)
CT shows cysts (hence the name Pneumocystis) but almost never pleural effusions

Clinical Features

- symptoms of pneumonia: fever, non-productive cough, progressive dyspnea (and hypoxia)
- classic CXR findings of interstitial pneumonia
- most clinical disease is due to reactivation of latent infection or reinfection by a different genotype in immunocompromised patients (steroid use, HIV)

Investigations

- CXR: bilateral symmetrical interstitial infiltrates
- ABG: reduced pO_2 and elevated alveolar-arterial (A-a) gradient
- serum LDH: elevated (>220 IU/L)
- induced sputum or lower airway sampling: positive for Pneumocystis, traditional test was immunofluorescence however many labs using quantitative PCR

Treatment and Prevention
- oxygen to keep SaO_2 >90%
- antimicrobial options
  - TMP/SMX (PO or IV) is preferred therapy, even for those taking this for prophylaxis
  - dapsone and TMP
  - clindamycin and primaquine
  - pentamidine (IV) is second line in severe disease
  - atovaquone
- corticosteroids used as adjuvant therapy in those with severe hypoxia (pO_2 <70 mmHg or A-a gradient O_2 >35 mmHg)
- prophylactic TMP/SMX for those at high-risk of infection (HIV patients when CD4 <200 cells/mm^3 or non-HIV immunocompromised patients under specific conditions)

Cryptococcus spp.

Etiology
- inhalation of airborne encapsulated yeast from soil contaminated with pigeon droppings (*C. neoformans*) or certain tree species such as Eucalyptus or Douglas fir (*C. gatti*)
- *C. neoformans* tends to affect immunocompromised hosts vs. *C. gatti* which tends to affect immunocompetent hosts

C. gattii has a limited geographical distribution including Vancouver Island, Northern Australia, and Papua New Guinea

Clinical Features
- asymptomatic
- pulmonary
  - usually asymptomatic or self-limited pneumonitis
  - only 2% of HIV+ patients present with pulmonary symptoms including productive cough, chest tightness, and fever
- disseminated
  - frequently disseminates in HIV+ population
  - CNS: meningitis (leading cause of meningitis in patients with HIV)
  - skin: umbilicated papules that resemble large lesions of *Molluscum contagiosum*
  - other: bone, lymph nodes, bone marrow, soft tissues, eyes, prostate

Investigations
- serum cryptococcal antigen
- CSF for meningitis: India-ink stain or cryptococcal antigen test, culture to confirm
- lateral flow cryptococcal antigen assay from serum and CSF
- LP with measurement of opening pressure

India-ink sensitivity for Cryptococcus is only 50% (higher in HIV patients); now replaced by cryptococcal antigen test in most laboratories

Treatment
- in patients with HIV who have cryptococcal meningitis or severe pulmonary disease:
  - amphotericin B (+ flucytosine) is used in the first 2 wk for induction therapy; limited duration due to side effects
  - switch to fluconazole for at least 8 wk as consolidation therapy, then continue at lower dose for prolonged maintenance
  - serial lumbar puncture or other method of managing increased ICP an important adjunct to therapy

Candida albicans

Etiology
- overgrowth of *C. albicans* (normally found as part of the microbiome of the skin, mouth, vagina, and GI tract)
- risk factors for overgrowth:
  - immunocompromised state (DM, corticosteroids)
  - critically ill patients (broad-spectrum antibiotic use, central venous catheters, total parenteral nutrition)
  - obesity: maceration and moisture in intertriginous areas, pannus, under breasts

Clinical Features
- mucocutaneous
  - oral thrush, esophagitis (chest pain, odynophagia), vulvovaginitis (see Gynecology, GY26), balanitis, cutaneous (diaper rash, skin folds, folliculitis), chronic mucocutaneous
  - small satellite lesions beyond the margin of the rash
- invasive
  - candidemia, endophthalmitis, endocarditis, UTI (upper tract), hepatosplenic disease

Treatment
- thrush: clotrimazole troches, miconazole mucoadhesive buccal tablets, or nystatin suspension or pastilles for mild disease, fluconazole for severe or refractory disease
- vulvovaginal candidiasis: topical agents (imidazole or nystatin), oral fluconazole for recurrent disease
- cutaneous infection: topical imidazole
- opportunistic infections in HIV, other systemic infections: fluconazole or echinocandin
- chronic mucocutaneous: azoles

Aspergillus spp.

Etiology
- infection with *Aspergillus* fungi (*A. fumigatus*, *A. flavus*) which is found ubiquitously in the air and the environment
- *Aspergillus* produces a toxin called aflatoxin that contaminates nuts, grains, and rice

Clinical Features
- allergic bronchopulmonary aspergillosis (ABPA)
  - IgE-mediated asthma-type reaction with dyspnea, high fever, and transient pulmonary infiltrates
  - occurs more frequently in patients with asthma and allergies
- aspergilloma (fungus ball)
  - ball of hyphae in a pre-existing lung cavity
  - symptoms range from asymptomatic to massive hemoptysis
  - CXR: round opacity surrounded by a thin lucent rim of air, often in upper lobes ("air crescent" sign)
- invasive aspergillosis
  - associated with prolonged and persistent neutropenia or transplantation
  - pneumonia – most common
  - may disseminate to other organs: brain, skin
  - severe symptoms with fever, cough, dyspnea, cavitation; fatal if not treated early and aggressively
  - CXR: local or diffuse infiltrates ± pulmonary infarction, pulmonary nodules with surrounding ground glass ("halo" sign)
- mycotoxicosis
  - aflatoxin produced by *A. flavus* (nuts, grains, rice)
  - results in liver hemorrhage, necrosis, and hepatocellular carcinoma formation

Treatment Options
- voriconazole or amphotericin B for invasive aspergillosis
- surgical resection for aspergilloma; a bronchial artery embolization for severe hemoptysis due to erosion of bronchial arteries from aspergilloma
- corticosteroids ± itraconazole for ABPA

See Landmark Infectious Disease Trials table for more information on the voriconazole vs. amphotericin B for invasive aspergillosis trial. It compared voriconazole with amphotericin B for primary therapy of invasive aspergillosis.

PARASITIC INFECTIONS

Protozoa – Intestinal/Genitourinary Infections

Entamoeba histolytica (Amoebiasis)

Etiology
- infection with *E. histolytica* occurs when the cysts are transmitted via the oral-fecal route in areas of poor sanitation that have been contaminated by other infected humans, or via sexual activity
- seen in migrants, travellers, institutionalized individuals, Indigenous peoples, MSM

Clinical Features
1. asymptomatic carriers
2. amoebic dysentery
   - abdominal pain, cramping, colitis, dysentery, low grade fever with bloody diarrhea secondary to local tissue destruction, and ulceration of large intestine
3. amoebic abscesses (liver abscesses, see General and Thoracic Surgery, GS52)
   - most common in liver (hematologic spread); presents with right upper quadrant pain, weight loss, fever, hepatomegaly
   - can also occur in lungs and brain

Investigations
- serology, fecal/serum antigen testing, stool microscopic exam (for cysts and trophozoites), colon biopsy, single stool for multiplex enteric parasite PCR
- *E. histolytica* indistinguishable microscopically from the non-pathogenic *E. dispar* (distinguish by specific stool antigen detection or multiplex stool PCR assay)

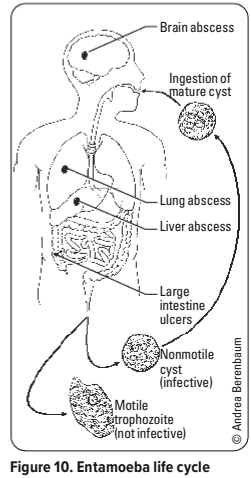

Figure 10. Entamoeba life cycle

Treatment and Prevention
- metronidazole
- for invasive disease or cyst elimination: follow with iodoquinol or paromomycin
- aspiration of hepatic abscess if risk of abscess rupture, poor response to medical therapy, or diagnostic uncertainty
- asymptomatic cyst shedding: iodoquinol or paromomycin alone
- good personal hygiene, purification of water supply by boiling, filtration (not chlorination)

Giardia lamblia

Etiology
- infection with G. lamblia occurs via the fecal-oral route with the ingestion of cysts from water/food contaminated by infected humans and other mammals (especially in the Rockies)
- risk factors: travel, camping, institutions, daycare centres, MSM

Clinical Features
- giardiasis ("beaver fever")
  - symptoms vary from asymptomatic to self-limited mild watery diarrhea to malabsorption syndrome (chronic giardiasis where the parasite coats the small intestine and thus prevents fat absorption)
  - nausea, malaise, abdominal cramps, bloating, flatulence, fatigue, weight loss, steatorrhea
  - no hematochezia (no invasion into intestinal wall), no mucous in stool

Investigations
- multiple stool samples (daily x 3 d) for microscopy; single stool for multiplex enteric parasite PCR; stool antigen used occasionally
- occasionally small bowel aspirate or biopsy

Treatment and Prevention
- metronidazole; nitazoxanide if symptomatic
- good personal hygiene and sanitation, water purification (iodine better than chlorination), outbreak investigation

Trichomonas vaginalis

Etiology
infection with *T. vaginalis* occurs via sexual contact

Trichomonas causes 25% of vaginitis

Clinical Features
- often asymptomatic (10-50%), especially males (occasionally urethritis, prostatitis)
- *Trichomonas* vaginitis (see Gynecology, GY26)
- vaginal discharge (profuse, malodorous, yellow-green or grey, frothy), pruritus, dysuria, dyspareunia

Investigations
- wet mount (motile parasites), antigen detection, culture
- urine PCR to detect in males

Treatment
- metronidazole for patient and partner(s)

Cryptosporidium spp.

Etiology
- infection with Cryptosporidium spp. via the fecal-oral route occurs with the ingestion of cysts from water contaminated by infected humans and other animals (including cows)
- risk factors: summer and fall, young children (daycare), MSM, contact with farm animals, immunodeficiency

Clinical Features
- range from self-limited watery diarrhea (immunocompetent) to chronic, severe, non-bloody diarrhea with nausea/vomiting, abdominal pain, and anorexia resulting in weight loss and death (immunocompromised)

Investigations
- modified acid-fast stain of stool specimen, microscopic identification of oocysts in stool or tissue, stool antigen detection by direct fluorescent antibody, single stool for multiplex enteric parasite PCR

Treatment and Prevention
- supportive care
- in HIV+ patients, (re)initiate ART and try to increase their CD4 count to >100; if fails, try nitazoxanide or macrolides
- good personal hygiene, water filtration

Blood and Tissue Infections

Plasmodium spp. (Malaria)

Etiology

- transmission of *Plasmodium* spp. (*P. falciparum, P. vivax, P. ovale, P. malariae, P. knowlesi*) primarily occurs during the blood meal of an infected female Anopheles mosquito
- sporozoites injected during the blood meal then infect human liver cells, where they multiply and are released as merozoites; merozoites infect red blood cells and cause disease
- infection with malaria parasites can also occur via vertical transmission (rare) or blood transfusion
- occurs in tropical/subtropical regions (sub-Saharan Africa, Oceania, South Asia, Central America, Southeast Asia, South America)

Clinical Features

- flu-like prodrome (may include fever, chills, fatigue, diaphoresis, cough, rash, arthralgias, myalgias, headache, GI symptoms)
- paroxysms of high spiking fever and shaking chills (due to synchronous systemic lysis of red blood cells) that can last several hours
  - *P. vivax* and *P. ovale*: chills and fever x 48 h but can be variable
  - *P. malariae*: chills and fever x 72 h but can be variable
  - *P. falciparum*: less predictable fever interval, can be highly variable
- abdominal pain, diarrhea, myalgia, headache, and cough
- hepatosplenomegaly and thrombocytopenia without leukocytosis
- >90% of patients infected with *P. falciparum* are ill within 30 d
- relapsing malarial attacks may occur after many months due to the reactivation (entering the erythrocytic cycle) of dormant liver hypnozoites of either *P. ovale* or *P. vivax*
- complications:
  - *P. falciparum* (most common and most lethal): CNS involvement (cerebral malaria = seizures and coma), severe anemia, acute kidney injury, ARDS, primarily responsible for fatal disease
  - *P. knowlesi*, and rarely *P. vivax*, can be fatal

Investigations

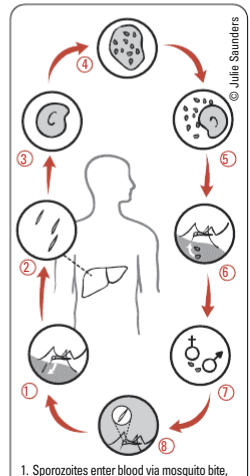
- CBC screen (assess for triad of: thrombocytopenia, elevated LDH, and anemia)
- microscopy: blood smear q12-24 h (x3) to rule out infection
  - thick smear (Giemsa stain) for presence of organisms
  - thin smear (Giemsa stain) for species identification and quantification of parasites
- rapid antigen detection tests
- PCR

Treatment and Prevention

- all spp. of malaria can lead to severe infection *(P. falciparum* most likely to cause severe disease and death)
  - markers of severity: clinical features + parasitemia
  - in any patient with clinical evidence of severe disease: parenteral treatment (artemisinin combination therapy)
- *P. falciparum*: most areas of the world show chloroquine resistance – check local resistance patterns
  - artemisinin combination therapy (e.g. artesunate + doxycycline or artemether-lumefantrine)
  - atovaquone/proguanil combination (Malarone®)
  - quinine + doxycycline or clindamycin
  - mefloquine and artemisinin resistance increasing in southeast Asia (check local resistance)
- *P. vivax, P. ovale*: chloroquine (and primaquine to eradicate liver forms)
- *P. vivax*, chloroquine resistant: atovaquone/proguanil + primaquine or quinine and doxycycline + primaquine
- *P. malariae, P. knowlesi*: chloroquine
- prevention with antimalarial prophylaxis (although quality may vary regionally), covering exposed skin, insecticide-treated bed nets, insect repellent
- prevention of relapse for *P. vivax*: primaquine or the newly FDA-licensed tafenoquine (in patients ≥16 yr who are receiving appropriate antimalarial therapy for acute P. vivax infection)

Mefloquine for Preventing Malaria during Travel to Endemic Areas
Cochrane DB Syst Rev 2017;CD006491
Purpose: To summarize efficacy and safety of mefloquine used as prophylaxis for malaria in travellers.
Methods: Randomized control trials (for efficacy and safety) and non-randomized cohort studies (for safety) to compare prophylactic mefloquine with placebo, no treatment, or alternative antimalarial agent.
Results: Participants were more likely to discontinue mefloquine (6%) vs. atovaquone-proguanil (3%) due to adverse effects (including nausea, vomiting, abnormal dreams, insomnia, anxiety, and depressed mood during travel). No difference in serious adverse effects or discontinuation due to adverse effects was found between mefloquine and doxycycline or mefloquine and chloroquine.
Conclusions: Absolute risk of malaria during short-term travel appears low with mefloquine, doxycycline, and atovaquone-proguanil therapy. Choice of agent depends on how individual travellers assess importance of specific adverse effects, pill burden, and cost.

Malaria is the most common fatal infectious disease worldwide



1. Sporozoites enter blood via mosquito bite, infect liver
2. Hepatic infiltration
3. Infect red blood cells
4. Trophozoite divides asexually many times to produce schizont (contains merozoites)
5. Red blood cell lyses and merozoites attack other red blood cells (chills and fever)
6. Male and female gametocytes (from merozoites) ingested by mosquito during bite
7. Male and female gametocytes (from merozoites) fuse in mosquito gut; produce ookinete
8. Ookinete matures into an oocyst which contains individual sporozoites; migrates to mosquito salivary glands

Figure 11. Life cycle of *Plasmodium* spp.

Trypanosoma cruzi

Etiology
- found in Mexico, South America, and Central America
- transmission by reduviid insect vector ("Kissing Bug"), which defecates on skin and trypomastigotes in the stool are rubbed into bite site or intact mucous membranes by host
- trypomastigotes can penetrate intact buccal mucosa when orally inoculated (e.g. via sugar cane-sweetened unpasteurized juices)
  - also transmitted via placental transfer, organ transplantation, blood transfusion, and ingestion of food or drink contaminated by an infected triatomine
  - congenital acquisition increasingly recognized as a risk factor for Chagas disease being detected in non-endemic areas

Clinical Features
- American trypanosomiasis (Chagas disease)
  - acute: usually asymptomatic, local swelling at site of inoculation (Chagoma) with variable fever, lymphadenopathy, cardiomegaly, and hepatosplenomegaly
  - if inoculation via conjunctiva: "Romana's sign;" usually unilateral
  - acute myocarditis, pericardial effusion, meningoencephalitis in severe cases
  - chronic indeterminate phase: asymptomatic but increasing levels of antibody in blood; most infected persons (60-70%) remain in this phase, and do not go on to manifest a determinate form of Chagas disease
  - chronic determinate: leads to chronic dilated cardiomyopathy, esophagomegaly, and megacolon 10-25 yr after acute infection in 30-40% of infected individuals

Investigations
- wet prep and Giemsa stain of thick and thin blood smear, serology, PCR

Treatment and Prevention
- acute: benznidazole or nifurtimox
- indeterminate: increasing trend to treat as acute infection for children and adults under age 50
- chronic determinate: symptomatic therapy, surgery as necessary including heart transplant, esophagectomy, and colectomy; there is unlikely a clinical benefit to antiparasitic treatment at the determinate stage of disease
- insect control, bed nets

Toxoplasma gondii

Etiology
- infection with *T. gondii* occurs through exposure to cat feces (oocysts), ingestion of undercooked meat (tissue cysts), transplacental transmission, organ transplantation, gardening without gloves (cat oocyst exposure), whole blood transfusions, contaminated water sources

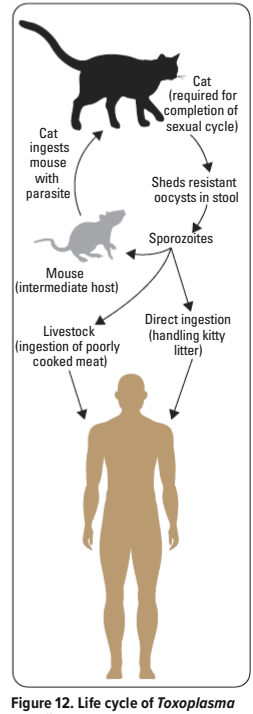
Clinical Features
- congenital
  - result of acute primary infection of mother during pregnancy (TORCH infection)
  - stillbirth (rare), chorioretinitis, blindness, seizures, severe developmental delay, microcephaly
  - initially asymptomatic infant may develop reactivation of chorioretinitis as adolescent or adult- blurred vision, scotoma, ocular pain, photophobia, epiphora, hearing loss, developmental delay
- acquired
  - usually asymptomatic or mononucleosis-like syndrome in immunocompetent patient
  - infection remains latent for life unless reactivation due to immunosuppression
- immunocompromised (most commonly AIDS with CD4 <200)
  - encephalitis with focal CNS lesions seen as single or multiple ring-enhancing masses on CT (headache and focal neurological signs)
  - lymph node, liver, spleen enlargement, and pneumonitis
  - chorioretinitis

Investigations
- serology, CSF Wright-Giemsa stain, antigen or DNA detection (PCR); pathology provides definitive diagnosis
- immunocompromised patients: consider CT scan (ring-enhancing lesion in cortex or deep nuclei) and ophthalmologic examination

Treatment and Prevention
- no treatment if: immunocompetent, not pregnant, no severe organ damage
- immunocompromised: pyrimethamine + sulfadiazine + folinic acid
- pregnancy: spiramycin if fetal status unknown, pyrimethamine + sulfadiazine + folinic acid if confirmed or highly suspected fetal infection, avoid undercooked meat and refrain from emptying cat litter boxes
- HIV: TMP/SMX
- proper hand hygiene, cook meat thoroughly to proper temperature

See Landmark Infectious Disease Trials table for more information on the BENEFIT trial. It details the role of trypanocidal therapy in patients with established Chagas cardiomyopathy.

Classic Triad of Congenital Toxoplasmosis
Chorioretinitis
Hydrocephalus
Intracranial calcifications



Cat
(required for completion of sexual cycle)
Sheds resistant oocysts in stool
Sporozoites
Direct ingestion (handling kitty litter)
Livestock (ingestion of poorly cooked meat)
Mouse (intermediate host)
Cat ingests mouse with parasite

Figure 12. Life cycle of *Toxoplasma gondii*

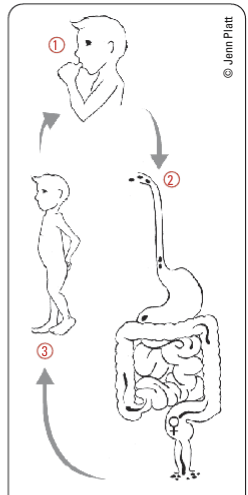
1/3 of Ontario's population is infected with *Toxoplasma gondii*

Helminths

Roundworms – Nematodes

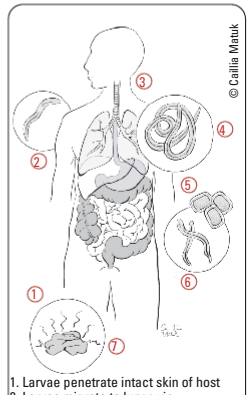
Table 26. Nematodes (Roundworms)

Nematode	Epidemiology	Transmission	Clinical Presentation	Management
Ascaris lumbricoides	Worldwide (most common in tropical and subtropical areas)	Human feces, ingestion of contaminated food or water containing eggs	Often asymptomatic, abdominal discomfort Heavy infections may cause intestinal blockage, growth impairment Cough, dyspnea, pulmonary infiltrates from larval migration through lungs (Löffler's syndrome)	Mebendazole OR albendazole OR pyrantel pamoate OR ivermectin
Trichuris trichiura (whipworm)	Worldwide (most common in tropical areas)	Ingestion of eggs in soil	Diarrhea (± mucous, blood), abdominal pain, rectal prolapse, stunted growth	Mebendazole OR albendazole
Onchocerca volvulus	Sub-Saharan Africa, Latin America	Blackfly bite	River blindness (onchocerciasis), dermatitis	Ivermectin + doxycycline
Wuchereria bancrofti	Tropics	Mosquito bite	Damage to lymphatics causes lymphadenopathy, lymphedema, lymphatic filariasis (elephantiasis), hydrocele Tropical pulmonary eosinophilia	Diethylcarbamazine + doxycycline
Loa loa	West and Central African rainforest (e.g. Cameroon, Central African Republic)	Deerfly bite	Loiasis mostly asymptomatic. Can have episodic angioedema (Calabar swellings), eye pain and itching from subconjunctival migration	Surgical removal of adult worms, diethylcarbamazine, albendazole
Enterobius vermicularis (pinworm)	Worldwide	Human host: fecal-oral self-inoculation and fomite person-to-person transfer Adult worms live in cecum and deposit eggs in peri-anal skin	Asymptomatic carriers or severe nocturnal peri-anal itching (pruritus ani) Occasional vaginitis, ectopic migration to appendix or other pelvic organs Abdominal pain, nausea/vomiting with high worm burden	Sticky tape test: eggs adhere to tape applied to perianal skin (need 5-7 tests to rule out) Examination of perianal skin at night may reveal adult worms Usually no eosinophilia as no tissue invasion Mebendazole, albendazole; pyrantel in pregnancy Change underwear, bathe in morning, pajamas to bed, wash hands, trim fingernails Treat all family members simultaneously Reinfection common
Strongyloides stercoralis (threadworm)	Subtropical, tropical, and temperate (including southern US)	Fecal contamination of soil: transmission via unbroken skin, walking barefoot Autoinfection: penetration of larvae through GI mucosa or perianal skin Adult worms live in mucosa of small intestine	One of few worms able to multiply in human host Mostly asymptomatic infection or can have pruritic dermatitis at site of larval penetration Transient pulmonary symptoms during pulmonary migration of larvae (eosinophilic pneumonitis = Löffler's syndrome) Abdominal pain, diarrhea, pruritus ani, larva currens (itchy rash) Hyperinfection: occasional fatal cases caused by massive auto-infection in immunocompromised host; immunoablative therapy, including high-dose corticosteroids, is the most common risk factor for disseminated infection	Ivermectin and/or albendazole



1. Embryonated eggs ingested by humans
2. Larvae hatch in small intestine
3. Females migrate out anus at night

Figure 13. Life cycle of Enterobius



1. Larvae penetrate intact skin of host
2. Larvae migrate to lungs via bloodstream
3. Larvae crawl up trachea and down to GI tract (cough/swallow)
4. Adult worms in intestine
5. Eggs produced in bowel
6. Larvae
7. Bowel movement containing larvae

Figure 14. Life cycle of Strongyloides

Flatworms – Cestodes/Trematode

Table 27. Cestodes/Trematodes (Flatworms)

	Epidemiology	Transmission	Clinical Presentation	Treatment
CESTODES				
***Taenia solium* (pork tapeworm)**	Worldwide, but more common in places with poor sanitation	Undercooked pork (larvae), human feces (eggs)	Taeniasis: mild GI symptoms Cysticercosis: mass lesions in CNS, eyes, skin, seizures	Corticosteroids + albendazole + praziquantel for most cysticercosis Antiepileptics if seizures Praziquantel for taeniasis
***Taenia saginata* (beef tapeworm)**	Worldwide, but more common wherever contaminated raw beef is eaten	Undercooked beef (larvae)	Taeniasis: mild GI symptoms	Praziquantel
Diphyllobothrium latum	Europe, North America, Asia	Raw fish	Vitamin B_{12} deficiency leading to macrocytic anemia and posterior column deficits	Praziquantel
Echinococcus granulosus	Rural areas, sheep-raising countries	Dog feces (eggs)	Liver/lung cysts (enlarge between 1-20 yr; may cause mass effect or rupture) Risk of anaphylaxis if cystic fluid released during surgical evacuation	Albendazole ± praziquantel alone Surgery + perioperative albendazole Percutaneous aspiration + perioperative albendazole
TREMATODES				
Clonorchis sinensis	Japan, Taiwan, China, Southeast Asia	Raw fish	Exists in bile ducts, causes inflammation and sometimes cholangiocarcinoma	Praziquantel
Schistosoma spp.	Africa, Southeast Asia, focal in Western Hemisphere	Fresh water exposure	Chronic sequelae secondary to long-term infection (e.g. chronic liver disease, squamous cell carcinoma (SCC) of the bladder)	Praziquantel

Schistosoma spp.

Etiology

infection with Schistosoma spp. (*S. mansoni, S. haematobium, S. japonicum*) occurs following penetration of unbroken skin by their larvae (cercariae) which are found in infested fresh water

- adult worms live in terminal venules of bladder/bowel passing eggs into urine/stool
- schistosomes cannot multiply in or pass between humans
- more common in individuals from sub-Saharan Africa, South America, Asia, Caribbean, Eastern Mediterranean/North Africa

Clinical Features

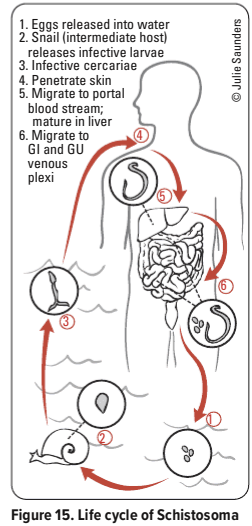
- most asymptomatic; symptoms seen in travellers (nonimmune)
- swimmer's itch: pruritic skin rash at site of penetration (cercarial dermatitis)
- acute schistosomiasis (Katayama fever): hypersensitivity to migrating parasites (4-8 wk after infection)
  - fever, hives, headache, weight loss, cough, abdominal pain, chronic diarrhea, high-grade eosinophilia
- chronic schistosomiasis (can persist for years):
  - *S. mansoni, S. japonicum*
  - worms in mesenteric vein, eggs in portal tracts of liver and bowel
  - heavy infections: intestinal polyps, portal and pulmonary HTN, splenomegaly (2° to portal HTN), hepatomegaly
  - *S. haematobium*
    - worms in vesical plexus, eggs in distal ureter and bladder induce granulomas and fibrosis
    - hematuria and obstructive uropathy; associated with squamous cell bladder cancer
  - neurologic complications: spinal cord neuroschistosomiasis (transverse myelitis), cerebral or cerebellar neuroschistosomiasis (increased ICP, focal CNS signs, seizures)
  - pulmonary complications: granulomatous pulmonary endarteritis, pulmonary HTN, cor pulmonale; especially in patients with hepatosplenic involvement

Investigations

- serology (high sensitivity and specificity), CBC (eosinophilia, anemia, thrombocytopenia), loop-mediated isothermal amplification, circulating serum antigen test
- *S. mansoni, S. japonicum*: eggs in stool, liver U/S shows peri-portal fibrosis, rectal biopsy
- *S. haematobium*: bladder biopsy, eggs in urine and occasionally stool, kidney and bladder U/S

Treatment and Prevention

- praziquantel
- add prednisone if acute schistosomiasis or neurologic complications develop
- proper disposal of human waste, molluscicide (pesticide against molluscs), avoidance of infested fresh water while travelling



1. Eggs released into water
2. Snail (intermediate host) releases infective larvae
3. Infective cercariae
4. Penetrate skin
5. Migrate to portal blood stream; mature in liver
6. Migrate to GI and GU venous plexi

Figure 15. Life cycle of Schistosoma

Ectoparasites

- scabies, lice
- see Dermatology, D33

Table 28. Important Exposures

Insect Bites	
Mosquito	*Plasmodium* spp. (malaria) Dengue Chikungunya *Wuchereria bancrofti* (lymphatic filariasis, aka elephantiasis) West Nile encephalitis Yellow Fever Japanese encephalitis Zika
Tick	*Borrelia burgdorferi* (Lyme disease) *Rickettsia rickettsii* (Rocky Mountain spotted fever)
Fly	*Trypanosoma brucei* spp. (human African trypanosomiasis (HAT), aka African sleeping sickness) *Leishmania* spp. (Leishmaniasis) *Bartonella bacilliformis* (bartonellosis)
Flea	*Yersinia* (Plague) *Tunga penetrans* (Tungiasis)
Mammal Bites	
Dog/Cat	Rabies, Pasteurella, anaerobes, *Streptococcus* spp., *S. aureus*, *Bartonella henselae*, *Clostridium tetani* (tetanus)
Human	*Streptococcus* spp., *S. aureus*, oral anaerobes, *Eikenella* spp.
Oral Exposures	
Unpasteurized Milk	*Brucella* spp., non-tuberculous Mycobacteria, *Salmonella* spp., *E. coli*, *Listeria* spp.
Undercooked Meat/Fish	Enteric bacteria, helminths, protozoa (e.g. Toxoplasma)
Water	Hepatitis A/E, norovirus, V. cholerae (cholera), *Salmonella*, *Shigella*, *Giardia*, poliovirus, *Cryptosporidium*, *Cyclospora*
Environmental Exposures	
Fresh Water	*Leptospira* spp., *Schistosoma* spp., *Acanthamoeba*, *Naegleria fowleri*
Soil	Hookworms, *Toxocara* spp. (visceral larva migrans), *Leptospira interrogans* (leptospirosis)

Travel Medicine

General Travel Precautions

- vector-borne: long sleeves, long pants, hats, insecticides (containing permethrin) applied to clothes, belongings, and bed nets; and skin repellents (e.g. DEET, icaridin) applied to exposed skin
- food/water: avoid eating raw meats/seafood, uncooked vegetables, and milk/dairy products; drink only bottled beverages, chlorinated water, boiled water
- recreation: caution when swimming in schistosomiasis-endemic regions (e.g. Lake Malawi), fresh-water rafting/kayaking, beaches that may contain human/animal waste products, near storm drains, after heavy rainfalls
- prophylaxis: malaria (chloroquine, mefloquine, atovaquone + proguanil, doxycycline), traveller's diarrhea (bismuth salicylate, rifaximin)
- standard vaccines up to date (hepatitis B, MMR, tetanus/diphtheria, varicella, pertussis, polio, influenza)
- travel vaccines: hepatitis A/B, Japanese encephalitis, typhoid fever, yellow fever, rabies, ETEC, cholera
- sexually transmitted and blood-borne infections: safe sex practices, avoidance of percutaneous injury through razors, tattoos, piercings

Infectious Diseases to Consider

- vector-borne: malaria, dengue fever, chikungunya, yellow fever, spotted fever rickettsioses, West Nile virus, trypanosomiasis, Japanese encephalitis, tick-borne encephalitis, leishmaniasis, Zika virus, filariasis
- sexually transmitted: HIV, HBV, acute HSV, syphilis, usual STIs, e.g. gonorrhea and chlamydia
- zoonotic: rabies, hantavirus, tularemia, Q fever, anthrax, brucellosis, Ebola
- airborne: TB, measles, varicella
- food/water: HAV, HEV, brucellosis, typhoid, paratyphoid, amoebiasis, dysentery, traveller's diarrhea, cholera, *Campylobacter* spp.
- soil/water: schistosomiasis, strongyloidiasis, leptospirosis, cutaneous larva migrans, histoplasmosis, paracoccidioidomycosis

Fever in the Returned Traveller

Etiology

- commonly identified causes of fever in the returned traveller
  - parasitic: malaria (20-30%)
  - viral: non-specific mononucleosis-like syndrome (4-25%), dengue (5%), viral hepatitis (3%)
  - bacterial: typhoid from Salmonella (2-7%), rickettsioses (3%)
  - diverse group of causative pathogens: traveller's diarrhea (10-20%), respiratory tract infection (10-15%), UTI/STI (2-3%)
  - Fever in a returned traveller from a malaria endemic area is considered malaria until proven otherwise
- can be caused by routine infections that are common in non-travellers (e.g. URTI, UTI)
- less commonly, fever can be due to non-infectious causes (e.g. DVT/PE, drug fever, inflammatory disorder unmasked by travel-acquired infection)

History

- pre-travel preparation
- travel itinerary: when, where, why, what, who, how?
  - dates of travel (determine incubation period)
  - season of travel: wet or dry
  - destination: country, region (urban or rural), environment (jungle, desert, etc.)
  - purpose of trip
- persons visiting friends and family are more likely to be exposed to local population and pathogens
  - style of travel: lodgings, camping, adventure travelling
  - local population: sick contacts
  - transportation: use of animals
- exposure history
  - street foods, untreated water: increased risk of traveller's diarrhea, enteric fever
  - uncooked meat/unpasteurized dairy: increased risk of parasitic infection
  - body fluids (sexual contacts, tattoos, piercings, IVDU, other injections)
  - increased risk of HBV, HCV, HIV, GC, *C. trachomatis*, syphilis
  - animal/insect bites: increased risk of malaria, dengue, rickettsioses, rabies
- fever pattern
- incubation period: use the earliest and latest possible dates of exposure to narrow the differential diagnosis and exclude serious infections
  - <21 d: consider malaria, typhoid fever, dengue fever, chikungunya, Zika, rickettsioses, traveller's diarrhea, respiratory tract infections (e.g. ILI, COVID-19); exclude HBV, TB
  - >21 d: consider malaria, TB, typhoid fever; exclude dengue fever, chikungunya, traveller's diarrhea, rickettsioses
- body systems affected: GI, respiratory, CNS, skin

Investigations

- all travellers with fever should undergo the following tests
  - blood work: CBC and differential, liver enzymes, electrolytes, creatinine, thick and thin blood smears x3 (for malaria), blood C&S
  - urine: urinalysis, urine C&S if dysuria or other localizing signs
- special tests based on symptoms, exposure history, and geography
  - stool: C&S, O&P
  - CXR
  - viral serology (hepatitis, HIV)
  - dengue serology for IgM, dengue PCR

Treatment

- empiric treatment if ongoing fever for 48-72 h and negative malaria smears and all cultures pending
- travelled to India, Southeast Asia: azithromycin ± doxycycline
- travelled elsewhere: ciprofloxacin ± doxycycline

Table 29. Fever in the Returned Traveller

Illness	Geography/ Timing	Pathogen	Incubation Period	Clinical Manifestations	Diagnosis	Treatment
Malaria	Africa, India, Central and South America, Southeast Asia Usually rural, night-biting mosquitoes	*P. falciparum* *P. vivax* *P. malariae* *P. ovale* *P. knowlesi*	7-30 d to mo or yr	Fever and flu-like illness (shaking chills, headache, muscle aches, and fatigue) Nausea/vomiting and diarrhea Anemia and jaundice *Plasmodium falciparum*: (severe) kidney failure, seizures, mental confusion, prostration, coma, death, respiratory failure	Blood smear (thick and thin) x3 Rapid diagnostic test (with smear or PCR confirmation) Antigen detection PCR	Artesunate (for severe disease) + Malarone®, doxycycline, or clindamycin Quinine sulfate + doxycycline or clindamycin Chloroquine + primaquine
Dengue	Southeast Asia, Caribbean Usually urban, day-biting mosquitoes	Dengue viruses 1-4	3 d to 2 wk	Sudden onset of fever, headache, retro-orbital pain, myalgias, and arthralgias Leukopenia Thrombocytopenia hemorrhagic manifestations (rare in travellers)	Anti-dengue IgM positivity PCR	Symptom relief: acetaminophen (avoid using NSAIDs and ASA because of antiplatelet properties)
Typhoid (enteric fever)	Global but mostly Indian subcontinent	*Salmonella enterica* serotype *Typhi* or serotype *Paratyphi*	3 to 60 d	Sustained fever 39°-40°C (103°-104°F) Abdominal pain, headache, loss of appetite, cough, constipation	Stool, urine, or blood culture positive for *S.* ser. Typhi or S. ser. Paratyphi	Quinolone antibiotic (e.g. ciprofloxacin), ceftriaxone, or macrolide
Tick Typhus	Mediterranean, South Africa, India	*Rickettsia*	1 to 2 wk	Fever, headache, myalgia, spotted rash Eschar at site of tick bite Thrombocytopenia Elevated liver enzymes	Serology Presence of classic tick eschar	Doxycycline
TB	Global	*M. tuberculosis*	Variable	Fever, cough, hemoptysis	CXR Sputum culture and acid-fast stain Nucleic Acid Amplification Test (NAAT)	Isoniazid (INH), rifampin (RIF), Pyrazinamide (PZA), Ethambutol (EMB) + Vitamin B6
Mononucleosis	Caribbean, Central and South America	EBV or CMV	30 to 50 d	Malaise, fatigue, pharyngitis, lymphadenopathy, splenomegaly	Atypical lymphocytes on blood smear and positive heterophilic antibody (monospot) test	Acetaminophen or NSAIDs, fluids
Zika Virus Disease	Africa, Southeast Asia, South America; spreading	Zika virus	Unknown, likely 3 to 12 d	Headache, malaise, myalgia, arthralgia, mild fever, rash, conjunctivitis	RT-PCR Serology	Rest, fluids, analgesics/ antipyretics (avoid NSAIDs until dengue ruled out), condom use, avoid pregnancy

Fever of Unknown Origin

Table 30. Classification of Fever of Unknown Origin (FUO) – Temp >38.3°C/101°F on Several Occasions

Classical FUO	Nosocomial FUO	Neutropenic FUO	HIV-associated FUO
Duration >3 wk	Hospitalized patient Infection not present/incubating on admission	Neutrophil count <500/mL or is expected to fall to that level in 1-2 d	HIV infections Duration >4 wk for outpatients, >3 d for hospitalized patients
Diagnosis uncertain after 3 outpatient visits or 3 d in hospital or 1 wk of intensive ambulatory investigation	Diagnosis uncertain after 3 d of investigation, including at least 2 d incubation of cultures	Diagnosis uncertain after 3 d of investigation, including at least 2 d incubation of cultures	Diagnosis uncertain after 3 d of investigation, including at least 2 d incubation of cultures

Causes of Nosocomial FUO
B, C, D, E

Bacterial and fungal infections of respiratory tract and surgical sites
Catheters (intravascular and urinary)
Drugs
Emboli

Etiology of Classic FUO

- infectious causes (~30%)
  - TB: extrapulmonary (most common), miliary, pulmonary (if pre-existing disease)
  - abscess: subphrenic, liver, splenic, pancreatic, perinephric, diverticular, pelvic, psoas
  - osteomyelitis
  - bacterial endocarditis (culture negative)
  - other: viral (CMV, EBV, HIV), bacterial (brucellosis, bartonellosis), fungal (histoplasmosis, cryptococcosis), parasitic (toxoplasmosis, leishmaniasis, amoebiasis, malaria)
- neoplastic causes (~20%)
  - most commonly lymphomas (especially non-Hodgkin) and leukemias, multiple myeloma, myelodysplastic syndrome
  - solid tumours: renal cell carcinoma (most common), breast, liver (hepatocellular carcinoma), colon, pancreas, or liver metastases
- collagen vascular diseases (~30%)
  - SLE, RA, rheumatic fever, vasculitis (temporal arteritis, polyarteritis nodosa), juvenile RA, Still disease
- miscellaneous (~20%)
  - drugs (e.g. antimicrobials, anti-arrhythmics), factitious fever
  - sarcoidosis, granulomatous hepatitis, IBD
  - hereditary periodic fever syndromes (e.g. familial Mediterranean fever)
  - venous thromboembolic disease: PE, DVT
  - endocrine: thyroiditis, thyroid storm, adrenal insufficiency, pheochromocytoma
  - unknown in 30-50% despite detailed workup

Approach to Classic FUO

- careful and repeated history: travel, environmental/occupational exposures, infectious contacts, medication history, immunizations, TB history, sexual history, past medical history, comprehensive review of systems (including symptoms that resolved before interview)
- thorough physical exam: fever pattern, rashes (skin, mucous membranes), murmurs, arthritis, lymphadenopathy, organomegaly
- initial investigations as appropriate
  - blood work: CBC and differential, electrolytes, urea, Cr, calcium profile, liver enzymes, erythrocyte sedimentation rate (ESR), C-reactive protein (CRP), ferritin, muscle enzymes, rheumatoid factor (RF), antinuclear antibody (ANA), serum protein electrophoresis (SPEP), blood film
  - cultures: blood (x3 sets), urine, sputum, stool C&S and O&P, other fluids as appropriate
  - serology: HIV, Monospot, CMV IgM, syphilis
  - imaging: CXR, abdominal imaging
- if there are diagnostic clues from any of the above steps, proceed with directed exam, biopsies or invasive testing as required, followed by directed treatment once a diagnosis is established

if no diagnosis with the above, consider empiric therapy vs. watchful waiting

  - without intervention: patients that remain undiagnosed despite extensive workup have good prognosis
- immunocompromised hosts have increased susceptibility to infections from pathogens that are typically low virulence, commensal, or latent

Infections in the Immunocompromised Host

Factors that Compromise the Immune System

- general: age (very young or elderly), malnutrition
- immune disease: HIV, malignancies, asplenia (functional or anatomic), hypogammaglobulinemia, neutropenia
- DM
- iatrogenic: corticosteroids, chemotherapy, radiation treatment, anti-TNF therapy, other immunosuppressive drugs (e.g. in transplant patients)

Table 31. Types of Immunodeficiency

Type	Conditions	Vulnerable To
Cell-Mediated Immunity	HIV, Hodgkin, hairy cell leukemia, cytotoxic drugs, SCID, DiGeorge syndrome	Latent viruses Fungi Parasites Non-tuberculosis *mycobacterium* (NTM)
Humoral Immunity	CLL, lymphosarcoma, multiple myeloma, nephrotic syndrome, protein-losing enteropathy, burns, sickle cell anemia, asplenia, splenectomy, selective Ig deficiencies, Wiskott-Aldrich syndrome	Encapsulated organisms (*S. pneumoniae, H. influenzae, N. meningitidis, Salmonella enterica* serotype *Typhi*, GBS)
Neutrophil Function	Chemotherapy, myelodysplasia, paroxysmal nocturnal hemoglobinuria, radiation, cytotoxic drug therapy, C3 or C5 deficiencies, chronic granulomatous disease	Catalase-producing organisms (*Staphylococcus, Serratia, Nocardia, Aspergillus*)

Febrile Neutropenia

Definition

- fever (≥38.3°C/101°F or ≥38.0°C/100.4°F for ≥1 h)
- neutropenia: ANC (absolute neutrophil count) <1.0
- ANC = WBC x (%neutrophils + %bands)
- severe neutropenia: ANC <0.5

Pathophysiology

- decreased neutrophil production
  - marrow: infection, aplastic/myelophthisic anemia, leukemia, lymphoma, myelodysplastic syndromes
  - iatrogenic: cancer chemotherapy, radiation, drugs
  - deficiencies: vitamin B_{12}, folate
- increased peripheral neutrophil destruction
  - autoimmune: Felty's syndrome, SLE, antineutrophil antibodies
  - splenic sequestration

Epidemiology/Etiology

- most common life-threatening complication of cancer therapy
- 8 cases per 1000 cancer patients per yr in the U.S.
- causative organism identified only 1/3 of the time
- GN (especially *Pseudomonas*) historically most common
- GP more common now
- fungal superinfection if neutropenia prolonged or if concurrent antibiotic use (especially *Candida, Aspergillus*)
- frequently associated with IV lines, mucosal or GI infection. Typhlitis (inflammation of cecum) is a rare complication, but can lead to serious infection and poor outcomes

Investigations
- examine for potential sites of infection: mucositis and line infections are most common
- do NOT perform DRE; examine perianal region for perianal abscess
- blood C&S (x2 sets), urine C&S, culture all indwelling catheter ports, ± sputum C&S and nasopharyngeal swab for respiratory viruses, stool for testing if diarrhea
- CBC and differential, Cr, urea, electrolytes, AST/ALT, total bilirubin, chest imaging (CXR or CT)

Treatment
- most hospitals have their own specific protocol so check local guidelines first (see *Figure 16*)
- prophylaxis against febrile neutropenia (FN) with granulocyte colony-stimulating factor (G-CSF) and granulocyte-macrophage colony-stimulating factor (GM-CSF) decreases hospitalization without affecting mortality (indicated if risk of FN ≥20% or if FN has occurred in a previous chemotherapy cycle)

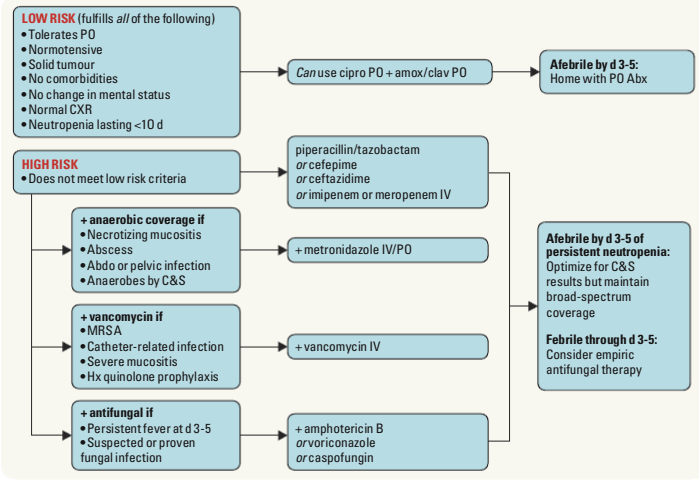

Figure 16. Example of treatment protocol for febrile neutropenia

Infections in Solid Organ Transplant Recipients

- infection is a leading cause of early morbidity/mortality in transplant recipients
- infection depends on degree of immunosuppression
- common infections <1 mo post-transplant
  - donor-derived infections
  - bacterial infection of wound/lines/lungs, herpetic stomatitis
- common infections >1 mo post-transplant
  - viral (especially CMV, EBV, VZV)
  - fungal (especially *Aspergillus, Cryptococcus, P. jirovecii*)
  - protozoan (especially *Toxoplasma*)
  - unusual bacterial/mycobacterial infections (especially TB, *Nocardia, Listeria*)

Prophylactic Vaccinations Given Before Transplant
- to all transplant patients: DTaP, pneumococcal, influenza, hepatitis A and B, COVID-19
- in select patients: MMR, varicella, HPV, herpes zoster

Immune Reconstitution Inflammatory Syndrome

Definition
- a harmful inflammatory response directed against a previously acquired infection following a recovery of the immune system

Etiology
- paradoxical worsening of a successfully or partially treated opportunistic infection
- new onset response to a previously unidentified opportunistic infection
- the majority of cases are in patients with advanced HIV or immunosuppressed patients starting anti-retroviral therapy or discontinuing immunosuppressive therapy; sudden recovery from an immunosuppressive state towards a pro-inflammatory state directed towards subclinical infection results in fever and inflammation

- can occur in response to multiple infections
  - Mycobacteria (*tuberculosis, avium complex*)
  - *Cryptococcus*
  - *Pneumocystis*
  - *Toxoplasma*
  - HBV and HCV
  - herpes viruses (VZV reactivation, HSV, CMV)
  - JC virus (progressive multifocal leukoencephalopathy)
  - Molluscum contagiosum
  - COVID-19
- clinical features are dependent on the type and location of the pre-existing infection
- thought to be worse with quick increase in CD4 count and with lower pre-treatment CD4 count
- non-HIV conditions with documented immune reconstitution inflammatory syndrome (IRIS): solid organ transplant recipients, post-partum women, neutropenic patients, anti-TNF therapy

Epidemiology
- in HIV-positive patients starting ART, IRIS reported to affect ~10%

Investigations
- IRIS is a diagnosis of exclusion
- rule out drug reaction, medication non-adherence, drug resistance

Treatment
- continue ARV therapy in HIV-positive patients with mild-moderate symptoms, but consider discontinuation if symptoms are life-threatening or potentially irreversible
- treat underlying infection; initiate treatment for some infections prior to ARV initiation
- consider starting corticosteroids/NSAIDs to decrease inflammatory response

A Simplified Look at Antibiotics

- general overview, see *Table 33, ID49* for more details

Table 32. Antibiotics Overview

Class and Drugs	GP							Anaerobes	GN					Atypicals	Other		
	Streptococcus spp.	*Staphylococcus* spp.			*Enterococcus* spp.		*C. difficile*		*H. influenzae*	*Neisseria* spp.		*Bacilli* (e.g. *E. coli, Klebsiella* spp.)	*Pseudomonas*	*Legionella, Chlamydia pneumoniae, Mycoplasma*	Rickettsia	*Chlamydia trachomatis*	*Syphilis*

Antimicrobials

Antibiotics

- empiric antibiotic therapy
  - choose antibiotic(s) to cover for most likely and lethal organisms for the type of infection prior to obtaining laboratory results (usually reserved for serious infections)
  - adjust antibiotic(s) based on C&S and clinical response
- if causative organism identified, use antibiotic to which organism is susceptible
- if causative organism not identified, re-evaluate need for ongoing antimicrobial therapy (and continue with empiric antibiotic(s) if indicated)

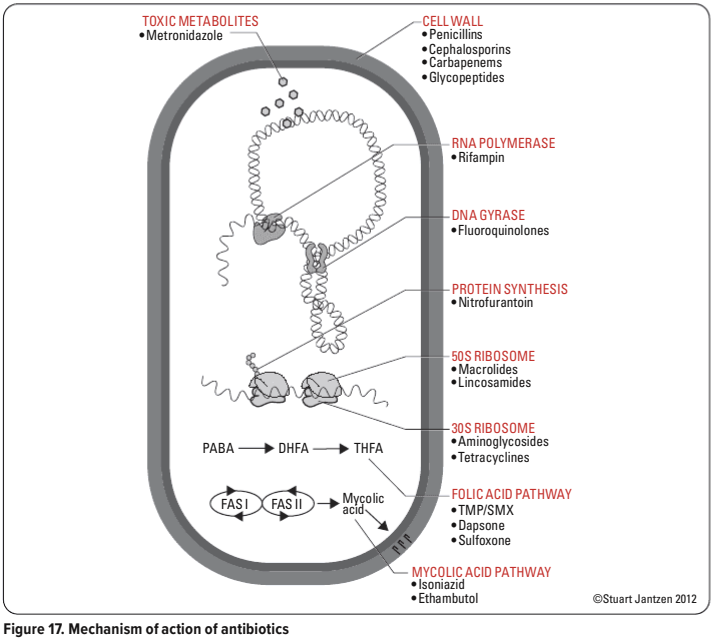

Figure 17. Mechanism of action of antibiotics

Reasons for Combination Therapy

- Polymicrobial infection
- Empiric therapy pending culture results
- Synergy for difficult to treat pathogens (e.g. *Enterococcus* spp. causing endocarditis)
- To prevent emergence of resistance

Bactericidal Antibiotics	Bacteriostatic Antibiotics

Table 33. Antibiotics

Class and Drugs	Coverage	Mechanism of Action	Adverse Effects	Indications	Contraindications
CELL WALL INHIBITORS					
Penicillins					
Benzyl penicillin - penicillin G IV/IM - penicillin V PO	GP except Staphylococcus, Enterococcus, N. meningitidis, Oral anaerobes Syphilis	Bactericidal: β-lactam inhibits cell wall synthesis by binding penicillin binding protein (PBP) preventing cross-linking of peptidoglycan	Immediate allergy (IgE): anaphylaxis, urticaria Late-onset allergy (IgG): urticaria, rash, serum sickness Interstitial nephritis Dose related toxicity: seizures Diarrhea	Mild to moderately severe infections caused by susceptible organisms including: actinomycosis, streptococcal pharyngitis, streptococcal skin and soft tissue infections, pneumococcal pneumonia, syphilis	Hypersensitivity to penicillin
Aminopenicillin - ampicillin IV - amoxicillin PO (Amoxil®)	Same as penicillin AND *Enterococcus* *Listeria* Some strains of: *H. influenzae, E. coli, K. pneumoniae*	See above	See above	Bacterial meningitis and endocarditis (IV ampicillin), acute otitis media (AOM), streptococcal pharyngitis, sinusitis, acute exacerbations of COPD, part of multidrug therapy for *H. pylori* treatment, Lyme disease, pneumococcal pneumonia, UTI (amoxicillin and ampicillin) for most enterococci and susceptible GN pathogens	Hypersensitivity to penicillin or β-lactam antibiotics
Isoxazolyl penicillin - cloxacillin - methicillin - nafcillin - oxacillin	Methicillin-sensitive *Staphylococcus aureus*; streptococci	See above	See above	Bacterial infections caused by staphylococci and streptococci including skin and soft-tissue infections	Hypersensitivity to cloxacillin or any penicillin
β-lactam combinations - amoxicillin-clavulanate (Clavulin®, Augmentin®) - piperacillin/tazobactam (Tazocin®) -ceftolozane/tazobactam	Same as penicillin AND *Staphylococcus* *H. influenzae* *Enterococcus* Anaerobes (oral and gut) *P. aeruginosa* (piperacillin-tazobactam) Ceftolozane/tazobactam primarily used for resistant GN	β-lactamase produced by certain bacteria inactivate β-lactams Lactamase inhibitors prevent this process, preserving antibacterial effect of β-lactams	See above	Various β-lactamase producing bacteria, amoxicillin-clavulanate-sensitive bacteria including URTI, sinusitis, AOM, skin and soft tissue infections, UTI, and severe intra-abdominal and pelvic infections Ceftolozane-tazobactam, ceftazidime-avibactam, meroepenem-vaborbactam, and imipenem-relebacatam used to treat resistant GN infections	Hypersensitivity to penicillin or cephalosporin History of amoxicillin-clavulate-associated jaundice or hepatic dysfunction
Cephalosporins					
PO 1° cephalexin (Keflex®)	IV cefazolin (Ancef®)	GP Good with the exception of *Enterococcus* and MRSA	GN *E. coli, Klebsiella, Proteus, H. influenzae* (not all isolates)	Bactericidal: β-lactam inhibits PBP, prevents cross-linking of peptidoglycan, less susceptible to penicillinases	10% penicillin allergy cross-reactivity	Skin and soft tissue infections, prevention of surgical site infections (cefazolin); infections caused by susceptible organisms (especially *Staphylococcus* and *Streptococcus* infections)	Hypersensitivity to cephalosporins or other β-lactam antibiotics
2° cefuroxime (Ceftin®) cefprozil (Cefzil®)	cefuroxime (Zinacef®) cefoxitin	Weaker activity than 1°	More coverage than 1° (includes anaerobes)	See above	See above	Upper and lower RTI, pneumococcal pneumonia, soft tissue infections	See above
3° cefixime (Suprax®)	ceftriaxone (Rocephin®) cefotaxime (Claforan®) ceftazidime (Fortaz®)	*S. aureus* + streptococcal coverage (cefotaxime and ceftriaxone) especially *S. pneumoniae*	Broad coverage (includes *Pseudomonas* for ceftazidime only)	See above	~1% penicillin allergy cross-reactivity	Community-acquired pneumonia (cefotaxime, ceftriaxone), gonorrhea (ceftriaxone), community-acquired bacterial meningitis (ceftriaxone, cefotaxime), abdominal and pelvic infections (cefotaxime or ceftriaxone in combination with metronidazole), once-daily administration makes ceftriaxone convenient for outpatient IV therapy	Severe hypersensitivity (Type I) to other β-lactam antibiotics
4°	cefepime (Maxipime®)	Broad spectrum	Broad coverage including *Pseudomonas*	See above	See above	Empiric therapy for febrile neutropenia	See above
5°	Ceftobiprole (Zevtara ®) ceftaroline (Teflaro®)*	Broad coverage including MRSA	Broad coverage (except *Pseudomonas*)	See above	See above	Acute bacterial skin and skin structure infections, community-acquired pneumonia	See above
Other	Cefiderocol*	Broad spectrum	Broad coverage including Pseudomonas	See above	See above	Used to treat resistant GN infections	See above
Carbapenems							
imipenem (Primaxin®)	GP except MRSA GN including *Pseudomonas + Enterobacter*, extended-spectrum β-lactamases (ESBLs), anaerobes			β-lactam inhibits PBP and prevents cross-linking of peptidoglycan	Penicillin allergy cross-reactivity Seizures	Treatment of infections caused by GNB producing extended-spectrum β-lactamases, serious infections caused by susceptible organisms	Hypersensitivity to imipenem Lowers seizure threshold
meropenem (Merrem®)	See above; does not cover *Enterococcus*			See above	See above	See above	Hypersensitivity to carbapenems
ertapenem (Invanz®)	GP except *Enterococcus*, MRSA GN including *Enterobacter* (but not *Pseudomonas*), anaerobes			See above	See above	See above; once-daily administration makes it convenient for outpatient IV therapy	Hypersensitivity to carbapenems

*Available in Canada through the Special Access Program

Table 33. Antibiotics

Class and Drugs	Coverage	Mechanism of Action	Adverse Effects	Indications	Contraindications
CELL WALL INHIBITORS					
Glycopeptides					
vancomycin (Vancocin®)	GP including MRSA, not VRE *C. difficile* if PO	Glycopeptide sterically inhibits cell wall synthesis	Red Man syndrome Nephrotoxicity Ototoxicity Thrombocytopenia	Severe or life-threatening GP infections, patients with β-lactam allergy May only be taken orally for severe *C. difficile* infection	Hypersensitivity to vancomycin
Other					
fosfomycin	GN (some coverage for *Pseudomonas* but lower compared to *Enterobacterales*) and GP (including *Enterococcus*)	Inhibiting cell wall synthesis at the initial step involving phosphoenolpyruvate synthase	PO – mild nausea, diarrhea possible IV – hypokalemia, hypernatremia, liver function test abnormalities	PO – uncomplicated urinary tract infections IV - complicated urinary tract infections, nosocomial lower RTI, osteomyelitis; bacterial meningitis	Hypersensitivity to fosfomycin
PROTEIN SYNTHESIS INHIBITORS (50S RIBOSOME)					
Macrolides					
erythromycin (Erybid®, Eryc®) †This agent is rarely used due to GI upset	GP except *Enterococcus* GN: *Legionella, B. pertussis* "Atypicals": *Chlamydophila, Mycoplasma*	Binds to 50S ribosomal subunit inhibiting protein synthesis	GI upset Acute cholestatic hepatitis Prolonged QT	Susceptible RTI, pertussis, diphtheria, Legionnaires' disease, skin and soft tissue infections	Hypersensitivity to erythromycin Concurrent therapy with astemizole, terfenadine
clarithromycin (Biaxin®)	See above, some mycobacteria	See above	See above	Susceptible RTI, skin infections, non-tuberculous mycobacterial infections, part of multidrug therapy for *H. pylori* treatment	Hypersensitivity to macrolides
azithromycin (Zithromax®)	See above, some mycobacteria	See above	See above	Susceptible RTI, acute exacerbations of COPD, community-acquired pneumonia, skin infections, *Campylobacter* infections if treatment indicated, chlamydia	Hypersensitivity to macrolides
Lincosamides					
clindamycin (Dalacin®)	GP except *Enterococcus*, most community-acquired MRSA anaerobes	Inhibits peptide bond formation at 50S ribosome	Pseudomembranous colitis and *C. difficile* GI upset	Treatment of suspected or proven infections caused by GP, anaerobes including skin and skin structure infections, oropharyngeal infections, in combination with GN coverage for intra-abdominal and pelvic infections	Hypersensitivity to clindamycin Infants <30 d Concurrent use or within 2 wk of monoamine oxidase (MAO) inhibitors
chloramphenicol	GP GN Anaerobes	Inhibits peptidyl transferase action of tRNA at 50S ribosome	Aplastic anemia Grey Baby syndrome	Serious infections by susceptible organisms when suitable alternatives are not available including meningococcal disease in patients with anaphylaxis to β-lactams	Hypersensitivity to chloramphenicol
linezolid (Zyvoxam®)	GP including VRE + MRSA	Binds 50S ribosome and prevents functional 70S initiation complex	HTN (acts as MAO inhibitor) Risks with prolonged use: myelosuppression, optic neuropathy, peripheral neuropathy	Vancomycin-resistant *Enterococcus faecium* infections including intra-abdominal, skin and skin structure, and urinary tract infections, MRSA infections as outpatient therapy	Hypersensitivity to linezolid, concurrent use or within 2 wk of MAO inhibitors
PROTEIN SYNTHESIS INHIBITORS (30S RIBOSOME)					
Aminoglycosides					
gentamicin tobramycin amikacin (Amikin®) plazomicin*	GN (includes *Pseudomonas*)	Binds 30S subunit of ribosome inhibiting protein synthesis	Nephrotoxicity (reversible) Vestibular and ototoxicity (irreversible) Vestibular toxicity is the most important aminoglycoside toxicity	GN infections when alternatives do not exist, UTIs, used in low doses for synergy with β-lactams or with vancomycin for the treatment of serious enterococcal infections	Pre-existing hearing loss and renal dysfunction
Tetracyclines					
tetracycline (Apo-Tetra®, Nu-TetraT®) minocycline (MinocinT®) doxycycline (Doxycin®) tigecycline (Tygacil®)	GP Anaerobes "Atypicals": *Chlamydophila, Mycoplasma, Rickettsia, Borrelia burgdorferi* *Treponema* Malaria prophylaxis (doxycycline) Tigecycline has activity against MRSA, VRE, and ESBL-producing *E. coli/K. pneumoniae*	Binds 30S subunit of ribosome inhibiting protein synthesis	GI upset Hepatotoxicity Fanconi's syndrome Photosensitivity Teratogenic Yellow teeth and stunted bone growth in children	*Rickettsial* infections, *Chlamydophila,* acne (tetracycline, minocycline), Pelvic Inflammatory Disease (PID) (step-down), malaria prophylaxis (doxycycline)	Severe renal or hepatic dysfunction Pregnancy or lactation Children under 12 yr

*Available in Canada through the Special Access Program

Table 33. Antibiotics

Class and Drugs	Coverage	Mechanism of Action	Adverse Effects	Indications	Contraindications
TOPOISOMERASE INHIBITORS					
Fluoroquinolones (FQs)					
ciprofloxacin (Cipro®) norfloxacin (Apo-Norflox®) ofloxacin (Floxin®) Respiratory FQs: levofloxacin (Levaquin®) moxifloxacin (Avelox®)	Variable GP activity GN (includes *Pseudomonas*) "Atypicals" levofloxacin and moxifloxacin cover *S. pneumoniae* moxifloxacin also has additional anaerobic coverage	Inhibits DNA gyrase	Headache, dizziness Allergy Seizures Prolonged QT Dysglycemia (levofloxacin, moxifloxacin) Tendonitis Tendon rupture	Upper and lower RTI (not ciprofloxacin unless susceptible organism isolated), UTI, prostatitis (not moxifloxacin), bone and joint infections for susceptible organisms, skin and soft tissue infections (levofloxacin, moxifloxacin), infectious diarrhea, meningococcal prophylaxis, intra-abdominal infections (moxifloxacin, ciprofloxacin in combination with metronidazole or clindamycin), febrile neutropenia prophylaxis (ciprofloxacin, levofloxacin) or management of "low-risk" febrile neutropenia (ciprofloxacin in combination with amoxicillin-clavulanate)	Pregnancy or lactation Children under 18 yr Concomitant use of medications that prolong QT interval
OTHER					
rifampin	GP cocci *N. meningitidis* *H. influenzae* Mycobacteria	Inhibits RNA polymerase	Hepatic dysfunction, P450 enzyme induction Orange tears/saliva/urine	Part of multidrug treatment for active TB, alone for treatment of latent TB, part of multidrug treatment for other mycobacterial infections, endocarditis involving prosthetic valve or other prosthetic device infections in combination with other antibiotic agents, prophylaxis for those exposed to people with *N. meningitidis* or HiB meningitis	Jaundice Not to be used as monotherapy (except for prophylaxis)
metronidazole (Flagyl®)	Anaerobes, protozoa	Forms toxic metabolites in bacterial cell which damage microbial DNA	Disulfiram-type reaction with EtOH Seizures Peripheral neuropathy	Protozoal infections (trichomoniasis, amebiasis, giardiasis), bacterial vaginosis, anaerobic bacterial infections	Pregnancy with trichomoniasis Disulfiram within 2 wk, alcohol within 3 d Active neurological disorders Hypothyroidism Hypoadrenalism
daptomycin	GP, including MRSA and VRE	Binds to cell wall and forms channels leading to intracellular K depletion	Skeletal muscle injury at high doses (elevated creatine phosphokinase) Peripheral neuropathy	Bacteremia, endocarditis, skin and soft tissue, and other infections due to resistant GP infections including MRSA and VRE	Known hypersensitivity Inactivated by surfactant, therefore not used in MRSA pneumonia Tx
colistin	GN	Disrupts bacterial cell membranes	Renal toxicity	Bacteremia, pneumoniae	Hypersensitivity, renal failure
ANTI-METABOLITE					
trimethoprim-sulfamethoxazole (TMP/SMX) (Septra®, Bactrim®)	GP, especially *S. aureus* (including most MRSA) GN: enteric *Nocardia* Other: *Pneumocystis*, *Toxoplasma*	Inhibits folic acid pathway (TMP inhibits dihydrofolate reductase (DHFR) and SMX competes with (para-aminobenzoic acid) PABA)	Hepatitis Stevens-Johnson syndrome Bone marrow suppression Hyperkalemia Drug toxicity (increases free levels of many drugs, including glyburide, warfarin)	Susceptible UTI, RTI, GI infections, skin and soft tissue infections caused by staphylococcal species, treatment and prophylaxis of *P. jirovecii* pneumonia	Hypersensitivity to TMP-SMX, sulfa drugs Infants <4 wk Hepatic or renal dysfunction Pregnancy and lactation
nitrofurantoin (MacroBID®, (Macrodantin®)	*Enterococcus*, *S. saprophyticus* GN (coliforms)	Reactive metabolites inhibit ribosomal protein synthesis	Cholestasis, hepatitis Hemolysis if G6PD deficiency Interstitial lung disease with chronic use	Lower UTI; not pyelonephritis or bacteremia	Anuria, oliguria, or significant renal impairment During or imminent labour Infants <1 mo of age
ANTI-MYCOBACTERIALS					
isoniazid (INH)	Mycobacteria	Inhibits mycolic acid synthesis	Hepatotoxicity Hepatitis Drug-induced SLE Peripheral neuropathy	Part of multidrug treatment for active TB, alone for treatment of latent TB	Drug-induced hepatitis or acute liver disease
rifampin (RIF)	Mycobacteria	Inhibits RNA polymerase	Hepatotoxicity P450 enzyme inducer Orange tears, saliva, urine	Part of multidrug treatment for active TB, alone for treatment of latent TB, part of multidrug treatment for other mycobacterial infections, adjunct for treating prosthetic device infection (bacterial biofilm), always use in combination with other antimicrobials to reduce emergence of resistance	Jaundice Not to be used as monotherapy (except for prophylaxis)
ethambutol	Mycobacteria	Inhibits mycolic acid synthesis	Loss of central and colour vision Neuropathy	Part of multidrug treatment for active TB and other mycobacterial infections	Renal failure
pyrazinamide (PZA)	Mycobacteria	Unknown	Hepatotoxicity Gout Gastric irritation	Part of multidrug treatment for active TB	Severe hepatic damage or acute liver disease Patients with acute gout
SULFONES					
dapsone sulfoxone	*M. leprae*, *P. jirovecii*, Toxoplasma	Inhibit folic acid synthesis by competition with PABA	Rash Drug fever Agranulocytosis	Part of multidrug treatment for *M. leprae*, part of treatment for *P. jirovecii* pneumonia (with TMP), *P. jirovecii* pneumonia prophylaxis, toxoplasmosis prophylaxis with pyrimethamine	G6PD Deficiency

*Available in Canada through the Special Access Program

Table 34. Antibiotics for Selected Bacteria

Pseudomonas	*S. aureus*	*Enterococcus*	*H. influenzae*	Anaerobes
ciprofloxacin	cloxacillin (MSSA)	ampicillin	amoxicillin-clavulanate	metronidazole
gentamicin tobramycin amikacin	1º cephalosporin (MSSA)	amoxicillin	2º/3º cephalosporin	clindamycin
piperacillin/ tazobactam	clindamycin	vancomycin	macrolides (clarithromycin, azithromycin)	amoxicillin-clavulanate
ceftazidime	cotrimoxazole (including MRSA)	nitrofurantoin (lower UTI)	levofloxacin	cefoxitin
cefepime	vancomycin (including MRSA)	linezolid for VRE	moxifloxacin	piperacillin/tazobactam
imipenem	linezolid (including MRSA)	daptomycin for VRE		moxifloxacin
	daptomycin (including MRSA)	tigecycline for VRE		ertapenem, imipenem, meropenem
	tigecycline (including MRSA)	penicillin		
	doxycycline (MSSA/MRSA)	imipenem		

Antivirals

Table 35. Antivirals

Class and Drugs	Coverage	Mechanism of Action	Adverse Effects	Contraindications
ANTI-HERPESVIRUS				
acyclovir valacyclovir (Valtrex®) (prodrug of acyclovir)	HSV-1,2 VZV	Guanosine analogue inhibits viral DNA polymerase	PO: well-tolerated IV: nephrotoxicity, CNS	Hypersensitivity to acyclovir or valacyclovir
famciclovir (Famvir®) penciclovir	HSV-1,2 VZV	See above	Headache, nausea	Hypersensitivity to famciclovir or penciclovir
ganciclovir (Cytovene®) valganciclovir (prodrug of ganciclovir)	CMV HSV-1,2, VZV, HHV-6, EBV	See above	Hematologic: neutropenia, thrombocytopenia, anemia	Hypersensitivity to ganciclovir or valganciclovir Possible cross-hypersensitivity between acyclovir and valacyclovir
foscarnet	CMV Acyclovir-resistant HSV, VZV	Pyrophosphate analogue inhibits viral DNA polymerase	Nephrotoxicity Anemia Electrolyte disturbance	Hypersensitivity to foscarnet
OTHER ANTIVIRALS				
(pegylated) interferon-α-2a or-2b	Chronic hepatitis B	Inhibits viral protein synthesis	"Flu-like" syndrome Depression Bone marrow suppression	Hypersensitivity to any interferon Cannot use in combination with ribavirin if renal impairment
lamivudine (Epivir®)	Chronic hepatitis B, HIV	See *HIV and AIDS, ID27*	See *HIV and AIDS, ID27*	See *HIV and AIDS, ID27*
tenofovir	Chronic hepatitis B, HIV	See *HIV and AIDS, ID27*	See *HIV and AIDS, ID27*	See *HIV and AIDS, ID27*
entecavir	Chronic hepatitis B	Deoxyguanosine analogue Inhibits viral DNA polymerase reducing viral DNA synthesis	Increased serum ALT, bilirubin Skin rash Glycosuria, hyperglycemia GI Hematuria Fatigue, headache Increased serum Cr	Hypersensitivity to entecavir or any component of the formulation HIV co-infection (if monotherapy)
glecaprevir and pibrentasvir	Chronic hepatitis C	glecaprevir: HCV NS3/4A protease inhibitor pibrentasvir: HCV Nonstructural protein 5A inhibitor (NS5A) that is essential for viral RNA replication and virion assembly	Nausea, diarrhea Fatigue, headache Pruritus Increased serum bilirubin	Moderate/severe hepatic impairment or history of hepatic decompensation Coadministration: atazanavir, rifampin, atorvastatin, dabigatran, ethinyl estradiol, or simvastatin
sofosbuvir and velpatasvir	Chronic hepatitis C	velpatasvir: HCV NS5A protein inhibitor sofosbuvir: prodrug, inhibits NS5B RNA-dependent RNA polymerase	Fatigue, headache Increased serum creatine kinase Skin rash Increased serum lipase Nausea Insomnia, irritability Asthenia HBV reactivation (in HBV/HCV coinfection)	Hypersensitivity to sofosbuvir, velpatasvir, or any component of the formulation
ribavirin (Virazole®)	Chronic hepatitis C (in combination with direct-acting antivirals), RSV Lassa fever	Guanosine analog with multiple postulated mechanisms of action	Hemolytic anemia Rash, conjunctivitis Highly teratogenic	Pregnant women and partners Hemoglobinopathies Concomitant α interferon use
cidofovir	Adenovirus CMV retinitis Acyclovir and foscarnet resistant HSV	Deoxycytidine analogue Inhibits DNA synthesis	Nephrotoxicity (proximal tubule dysfunction)	Renal failure: probenecid can reduce renal toxicity

Table 35. Antivirals

Class and Drugs	Coverage	Mechanism of Action	Adverse Effects	Contraindications
Neuraminidase inhibitors: zanamivir (Relenza®) oseltamivir (Tamiflu®)	Influenza A and B: treatment and prophylaxis	Inhibits neuraminidase, an enzyme required for release of virus from infected cells leading to prevention of viral aggregation	GI: nausea/vomiting, diarrhea Bronchospasm with zanamivir	Hypersensitivity to the neuraminidase inhibitors
remdesivir	Hospitalized COVID-19	Adenosine triphosphate analog Inhibitor of the SARS-CoV-2 RNA-dependent RNA polymerase Inhibits viral RNA synthesis	Bradycardia, hypotension Increased serum ALT, AST Hypersensitivity reactions (e.g. anaphylaxis, angioedema) Skin rash GI Prolonged prothrombin time Seizure	Hypersensitivity to remdesivir or any component of the formulation
nirmatrelvir/ritonavir (Paxlovid®)	COVID-19 infection within 5 days of symptom onset	nirmatrelvir: Peptidomimetic inhibitor of SARS-CoV-2 protease ritonavir: CYP3A inhibitor, increasing concentrations of nirmatrelvir	Hypertension Diarrhea, Dysgeusia Myalgia	Hypersensitivity to nirmatrelvir, ritonavir or any component of the formulation Co-administration of highly dependent CYP3A substrates or potent CYP3A inducers

Antifungals

Table 36. Antifungals

Class and Drugs	Coverage	Mechanism of Action	Adverse Effects	Contraindications
POLYENES				
amphotericin B (liposomal formulation is less toxic)	Endemic mycoses: Histoplasmosis Blastomycosis Coccidioidomycosis Pulmonary: Aspergillosis CNS: Cryptococcus	A polyene antimicrobial: inserts into fungal cytoplasmic membrane causing altered membrane permeability and cell death	Nephrotoxicity Hypo/hyperkalemia Infusion reactions: chills, fevers, headache Peripheral phlebitis	Hypersensitivity to amphotericin or any component of the formulation
nystatin (oral, topical)	Candidiasis: mucocutaneous, GI, oral (thrush), vaginal	See above Not absorbed from the GI tract	GI: nausea/vomiting, diarrhea Highly toxic if given IV	Hypersensitivity to nystatin or any component of formulation
IMIDAZOLES				
clotrimazole (Canesten®)	Oral and vulvovaginal candidiasis Dermatomycoses	All azoles: inhibit ergosterol synthesis and thereby alter fungal cell membrane permeability	Pruritus, skin irritation	Hypersensitivity to clotrimazole or any component of formulation
miconazole (Monistat®, Micozole®)	Vulvovaginal candidiasis Dermatomycoses		Vaginal burning Nausea/vomiting	Hypersensitivity to miconazole, milk protein concentrate, or any component of formulation
ketoconazole (Nizoral®)	Dermatomycoses Seborrheic dermatitis		Pruritus, skin irritation, GI nonspecific Results in decreased androgen and testosterone synthesis	Cross-sensitivity with other azoles possible Hepatic dysfunction Pregnant women or those that may become pregnant
TRIAZOLES				
fluconazole (Diflucan®)	*Candida* infections (mucosal and invasive) Cryptococcal meningitis (step-down therapy)	All azoles: inhibit ergosterol synthesis and thereby alter fungal cell membrane permeability	Elevated liver enzymes GI nonspecific	Cross-sensitivity with other azoles unknown Terfenadine of multiple doses ≥400 mg CYP3A4 substrates (QTc prolongation risk)
itraconazole (Sporanox®)	Sporotrichosis Onychomycoses Endemic mycoses: Histoplasmosis Blastomycosis Coccidioidomycosis		Elevated liver enzymes Rash GI Nonspecific HTN Hyperkalemia Peripheral edema	Cross-sensitivity with other azoles unknown Severe ventricular dysfunction Pregnant women or planning CYP2D6 inhibitors or eliglustat Hepatic and renal impairment
voriconazole (Vfend®)	Aspergillosis Candidiasis		Visual disturbance (30%) Hepatotoxicity Cutaneous photosensitivity Cutaneous squamous cell carcinoma with long-term use in immunosuppressed patients Prolonged QT Periostitis Neurologic toxicity	Cross-sensitivity with other azoles unknown May avoid or alter doses if co-administered with other CYP3A4 substrates, rifampin, carbamazepine, long-acting barbiturates, ritonavir, efavirenz, sirolimus, rifabutin, ergot alkaloids, St. John's wort, venetoclax, ivabradine
posaconazole (Posanol®, Noxafil®)	Candidiasis Aspergillosis Mucormycosis		Elevated liver enzymes Headache Prolonged QT	Coadministration of cisapride, ergot alkaloids, or sirolimus CYP3A4 substrates: HMG-CoA reductase inhibitors (e.g. atorvastatin, lovastatin, simvastatin) QT interval prolonging (e.g. pimozide, quinidine)
isavuconazole	Candidiasis (esophageal) - off label for HIV patients Aspergillosis Mucormycosis		Peripheral edema Headache, fatigue, insomnia Hypokalemia GI Elevated liver enzymes Dyspnea, cough	Hypersensitivity to isavuconazole or any component of the formulation Strong CYP3A4 inhibitors (e.g. ketoconazole, ritonavir) Strong CYP3A4 inducers (e.g. rifampin, carbamazepine, St. John's wort, long acting barbiturates) Moderate CYP3A4/5 inducers (e.g. efavirenz, etravirine) Familial short QT syndrome Pregnant women or planning

Table 36. Antifungals

Class and Drugs	Coverage	Mechanism of Action	Adverse Effects	Contraindications
ALLYLAMINES				
terbinafine (Lamisil®)	Dermatomycoses Onychomycoses	Inhibits enzyme needed for ergosterol synthesis	Rash, local irritation GI nonspecific Transaminitis	Active liver disease
ECHINOCANDINS				
caspofungin micafungin anidulafungin	Refractory aspergillosis Candidemia (azole-resistant)	Inhibits 1-3 β-D-glucan synthesis (needed for fungal cell wall)	Hepatotoxicity infusion and injection site reactions	

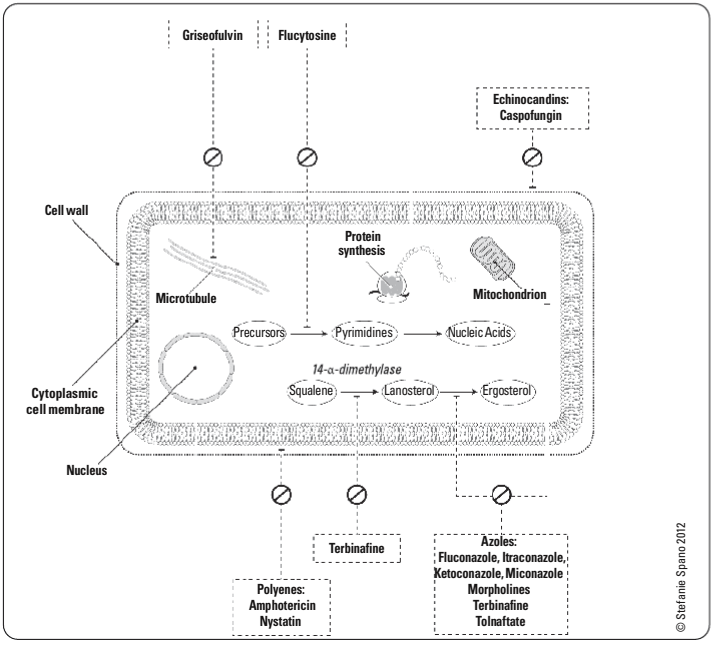

Figure 18. Mechanism of action of antifungals

Antiparasitics

Table 37. Antiparasitics

Class and Drugs	Coverage	Mechanism of Action	Adverse Effects	Contraindications
ANTIMALARIALS				
chloroquine	Malaria: treatment of erythrocytic phase of all five species of *Plasmodium* that infect humans Note: High resistance of *P. falciparum and P. vivax* in certain geographic areas	Inhibits parasite heme polymerase	CNS: blurred vision, retinopathy, dizziness Nonspecific GI (rare with prophylaxis)	Hypersensitivity to chloroquine or other 4-aminoquinoline Retinal or visual field changes
quinine	Malaria: treatment of all five species of *Plasmodium* that infect humans, including chloroquine-resistant *P. falciparum*		Cinchonism: ears (tinnitus, vertigo), eyes (visual disturbance), GI (nausea/vomiting, diarrhea), CNS (headache, fever) Hypoglycemia	Hypersensitivity to quinine, may have cross-sensitivity with quinidine Tinnitus, optic neuritis, hypoglycemia, history of blackwater fever or thrombocytopenic purpura due to quinine use Prolonged QT Myasthenia gravis
mefloquine (Lariam®)	Malaria: prophylaxis		CNS/Psych: irritability, nightmares, psychoses, suicide, depression, seizures, headache	History of seizures, psychosis, anxiety, depression, or other mental health diagnoses
primaquine	Malaria: treatment of liver hypnozoites of *P. vivax* and *P. ovale*; prophylaxis of all *Plasmodium* spp. *Pneumocystis jirovecii* (with clindamycin)	Interferes with mitochondrial function	Hemolytic anemia in G6PD deficient GI upset (take with food)	G6PD deficiency Concurrent or recent use of quinacrine Pregnancy
atovaquone/proguanil (Malarone®)	Malaria: treatment and prophylaxis of *P. falciparum*	Inhibits mitochondrial electron transport and dihydrofolate reductase	Nausea/vomiting, anorexia, diarrhea, abdominal pain (take with food)	Hypersensitivity to atovaquone or proguanil Severe renal impairment
artemisinin derivatives (artemether, artesunate, etc.) Note: marketed throughout the word in both endemic and non-endemic countries; neither licensed nor marketed in Canada, therefore available only via Health Canada Special Access Program	Malaria: treatment of all *Plasmodium* spp. Severe malaria (IV artesunate) Typically used in combination with a longer-acting agent from above	Binds iron, leading to formation of free radicals that damage parasite proteins	Transient neurologic deficits (nystagmus, balance disturbance) Transient neutropenia (at high doses of oral artesunate) Delayed hemolysis	Hypersensitivity to artemisinins
OTHER ANTI-PROTOZOAL				
iodoquinol (Diodoquin®)	Amebiasis: *E. histolytica, Dientamoeba fragilis, Balantidium coli, Blastocystis hominis*	Contact amebicide that acts in intestinal lumen by uncertain mechanism	GI: nausea/vomiting, diarrhea, abdominal pain CNS: headache, seizures, encephalitis	Hypersensitivity to any 8-hydroxyquinoline or iodine Patients with hepatic damage or optic neuropathy Pregnancy
metronidazole	Amebiasis: *E. histolytica*, *T. vaginalis, giardiasis, D. fragilis*	See *Antibiotics, ID50*		
nitazoxanide	*Cryptosporidium*, giardiasis, cyclosporiasis	Interferes with parasite anaerobic metabolism	Nausea/vomiting, diarrhea, abdominal pain, headache	Hypersensitivity to nitazoxanide
ANTI-HELMINTHICS				
praziquantel	*Schistosomiasis* and other flukes Tapeworms	Increases Ca^{2+} permeability of helminth cell membrane, causing paralysis and detachment	Nausea/vomiting, fever, dizziness	Ocular cysticercosis Concomitant use with strong CYP450 inducers
albendazole	Intestinal roundworms *Neurocysticercosis* *Echinococcus* Hydatid disease	Inhibits glucose uptake into susceptible parasites Microtubule inhibitor	Elevated liver enzymes Alopecia GI nonspecific Agranulocytosis	Pregnancy Ocular cysticercosis or intraventricular cysticercosis
mebendazole (Vermox®)	Intestinal roundworms: pinworm, whipworm, hookworm, roundworm (e.g. *Ascaris*)	Inhibits microtubule formation and glucose uptake	Nonspecific GI	Pregnancy Infants
ivermectin	*Strongyloidiasis* *Onchocerciasis* Scabies	Interferes with polarization of nerve and muscles cells in susceptible parasites leading to paralysis	Nausea, bloating, diarrhea, myalgias, lightheadedness, headache	Hypersensitivity to ivermectin Pregnancy
diethylcarbamazine	Wuchereria bancrofti Loa loa	Thought to immobilize microfilariae and disrupt surface membrane to enhance killing by host immune system	Anorexia, nausea/vomiting, headache, drowsiness, encephalitis, retinal hemorrhage Mazzotti reaction if coinfected with onchocerciasis	Pregnancy Onchocerciasis High-grade microfilaremia due to *Loa loa*

Landmark Infectious Diseases Trials

Trial Name	Reference	Clinical Trial Details
Respiratory Infections		
EPIC-HR	NEJM 2022;386:1397-1408	**Title:** Oral Nirmatrelvir for High-Risk, Non-hospitalized Adults with COVID-19 **Purpose:** To determine whether nirmatrelvir/ritonavir is safe and effective for the treatment of adults who are ill with COVID-19 and do not need to be in the hospital but are at an increased risk of developing severe illness. **Methods:** 2246 participants with confirmed diagnosis of SARS-CoV-2 infection were randomized (1:1) to receive nirmatrelvir/ritonavir or placebo orally every 12 h for 5 d (10 doses total). **Results:** Primary outcome measure was proportion of participants with COVID-19 related hospitalization or death from any cause; incidence was lower on day 28 by 6.32% in nirmatelvir group compared to placebo (relative risk reduction of 89.1%; P<0.0001). **Conclusions:** In early treatment of patients with both symptomatic COVID-19 and at high risk of progressing to severe illness, nirmatrelvir/ritonavir significantly reduces hospitalization and death.
PINETREE	NEJM 2022;386:305-315	**Title**: Early Remdesivir to Prevent Progression to Severe Covid-19 in Outpatients **Purpose**: To determine whether remdesivir in symptomatic, nonhospitalized patients with COVID-19 who are at high risk of disease progress prevents hospitalization. **Methods**: 562 patients were randomized within 7 d of symptoms onset to IV remdesivir (200 mg on day q1 and 100 mg on days 2 and 3) or placebo. Primary efficacy was a composite of COVID-19-reslated hospitalization or death from any cause by day 28. **Results**: COVID-19-related hospitalization or death from any cause occurred in 2 patients (0.7%) in the remdesivir group and in 15 (5.3%) in the placebo group. **Conclusions**: Among non-hospitalized patients who were at high risk for COVID-19 progression, a 3-day course of remdesivir resulted in an 87% lower risk of hospitalization or death than placebo.
ACTT-1	NEJM 2020;383:1813-26	**Title**: Remdesivir for the Treatment of Covid-19 — Final Report **Purpose**: To determine if remdesivir is effective against patients hospitalized with COVID-19 lower respiratory tract infection **Methods**: 1062 patients were randomized to either remdesivir (200 mg loading dose on day 1, followed by q100 mg daily for up to 9 additional days) or placebo for up to 10 d. Primary outcome: time to recovery define as either discharge from hospital or hospitalization for infection control purposes only. **Results**: Mean time to recovery for those randomized to remdesivir was 10 d compared to 15 d among those with placebo. Kaplan-Meier estimates of mortality were 6.7% with remdesivir and 11.9% with placebo by day 15. **Conclusions**: Remdesivir was superior to placebo in shortening time to recovery in adults who were hospitalized with COVID-19 and had evidence of lower respiratory tract infection.
RECOVERY	NEJM 2021;384:693-704	**Title:** Dexamethasone in Hospitalized Patients with COVID-19 **Purpose:** To assess if glucocorticoids can protect against inflammation-mediated lung injury and reduce progression to respiratory failure and death. **Methods:** 6425 hospitalized SARS-CoV-2 patients were randomized to receive either (1) dexamethasone (oral or IV, 6 mg daily) for up to 10 d or (2) usual standard of care alone. **Results:** Dexamethasone significantly reduced incidence of death as compared to usual care alone in patients receiving invasive mechanical ventilation (29.3% vs. 41.4%; RR 0.64; 95% CI 0.51-0.81) and among those receiving oxygen (23.3% vs. 26.2%; RR 0.82; 95% CI 0.72-0.94) but not among those without respiratory support (17.8% vs. 14.0%; RR 1.19; 95% CI 0.92-1.55). **Conclusion:** In patients hospitalized with COVID-19, dexamethasone lowers 28-d mortality in those receiving invasive mechanical ventilation or oxygen alone.
PneumA	JAMA 2003;290:2588-98	**Title:** Comparison of 8 vs. 15 Days of Antibiotic Therapy for Ventilator-Associated Pneumonia in Adults: A Randomized Trial **Purpose:** To identify the optimal duration of antimicrobial treatment for ventilator-associated pneumonia (VAP). **Methods:** 401 patients with VAP diagnosed by quantitative culture of bronchoscopic specimens who had received initial empiric antibiotic therapy were randomly assigned to receive either 8 d or 15 d of antibiotic therapy (regimen selected by treating physician). **Results:** As compared to 15-d therapy, 8-d therapy did not result in a significant difference in mortality (18.8% vs. 17.2% in 8-d and 15-d group, respectively; difference, 1.6%; 90% CI, -3.7% to 6.9%) or recurrent infections (28.9% vs. 26.0%; difference, 2.9%; 90% CI, -3.2% to 9.1%). 8-d therapy was associated with more mean antibiotic-free days (13.1 vs. 8.7; P<0.001). **Conclusion:** 8- and 15-d antibiotic treatment regimens demonstrated comparable clinical efficacy against VAP among patients who had received appropriate initial empiric therapy.
Meningitis		
Dexamethasone in Adults with Bacterial Meningitis. Gans et al. 2002	NEJM 2002;347:1549-56	**Title:** Dexamethasone in Adults with Bacterial Meningitis **Purpose:** To assess the efficacy of corticosteroids as an adjuvant treatment of acute bacterial meningitis in adults. **Methods:** 301 patients were randomly assigned to receive dexamethasone (10 mg) or placebo 15-20 min before or with the first dose of antibiotics and subsequently every 6 h for 4 d. **Results:** Dexamethasone treatment was associated with a significant reduction in the risk of an unfavourable outcome, defined as a score of 1-4 on the Glasgow Outcome Scale at 8 wk (relative risk (RR), 0.59; 95% CI, 0.37-0.94; P=0.03), as well as a significant reduction in in mortality (RR, 0.48, 95% CI, 0.24-0.96; P=0.04). **Conclusion:** In adults with acute bacterial meningitis, early treatment with dexamethasone significantly improves outcomes and does not increase the risk of GI bleeding.
Infective Endocarditis		
POET	NEJM 2019;380:415-24	**Title:** Partial Oral versus Intravenous Antibiotic Treatment of Endocarditis **Purpose:** To investigate whether a change from IV to oral antibiotics in stable left-sided IE would result in efficacy and safety profiles similar to those with continued IV treatment. **Methods:** 400 adults with IE on the left side of the heart, in stable condition, being treated with IV antibiotics (minimum 10 d) were randomized to continue IV treatment or to switch to oral antibiotics. Primary Outcome: Composite of all-cause mortality, embolic events, unplanned cardiac surgery, or relapse of bacteremia with the primary pathogen, from the time of randomization until 6 mo following completion of antibiotics. **Results:** The primary composite outcome occurred in 12.1% in the IV group and 9.0% in the oral group (between-group difference, 3.1 percentage points; 95% CI, -3.4 to 9.6; P=0.40), thus meeting noninferiority. **Conclusion:** Shifting to oral antibiotics was noninferior to continued IV antibiotics in patients with IE on the left side of the heart in stable condition.

Trial Name	Reference	Clinical Trial Details
Intraabdominal Infections		
STOP-IT	NEJM 2015;372:1996-2005	**Title:** Trial of Short-Course Antimicrobial Therapy for Intraabdominal Infection **Purpose:** To determine the appropriate duration of antimicrobial therapy for intraabdominal infection. **Methods:** 518 patients with complicated intraabdominal infection and adequate source control were randomly assigned to receive a fixed course of antibiotics for 4±1 d (experimental group) or until 2 d following the resolution of fever, leukocytosis, and ileus, up to maximum 10 d (control group). **Results:** There were no significant differences in the rates of surgical-site infection, recurrent intraabdominal infection, or death between treatment groups (21.8% vs. 22.3% in the experimental and control groups, respectively; absolute difference, -0.5; 95% CI, -7.0 to 8.0; P=0.92). The experimental group experienced a significantly shorter median duration of antibiotic therapy (4.0 d vs. 8.0 d; absolute difference, -4.0; 95% CI, -4.7 to -3.3; P<0.001). **Conclusion:** The outcomes after fixed-duration antibiotic therapy were similar to those after a longer course of antibiotics in patients with intraabdominal infections with adequate source control.
HIV and AIDS		
iPrEx	NEJM 2010;363:2587-99	**Title:** Preexposure Chemoprophylaxis for HIV Prevention in Men Who Have Sex With Men **Purpose:** To investigate the efficacy and safety of antiretroviral chemoprophylaxis for the prevention of HIV acquisition. **Methods:** 2499 HIV-seronegative men or transgender women who have sex with men were randomly assigned to receive emtricitabine plus tenofovir disoproxil fumarate (FTC-TDF), or placebo daily. **Results:** During median 1.2 yr follow-up, 100 participants became infected (36 in the FTC-TDF group vs. 64 in the placebo group), representing a 44% reduction in the incidence of HIV (95% CI, 15-63; P=0.005). Similar rates of serious adverse events were observed in both groups (P=0.57). **Conclusion:** Preexposure prophylaxis with antiretrovirals significantly reduced HIV infection risk in HIV-negative men and transgender women who have sex with men.
Prevention of HIV-1 Infection With Early Antiretroviral Therapy. Cohen et al. 2011	NEJM 2011;365:493-505	**Title:** Prevention of HIV-1 Infection With Early Antiretroviral Therapy **Purpose:** To investigate if immediate antiretroviral therapy could limit the transmission of HIV in serodiscordant couples. **Methods:** 1763 HIV-1-positive adults with an HIV-negative partner were randomly assigned to receive antiretroviral therapy either immediately or after a decline in the CD4 count or the onset of HIV-1-related symptoms. **Results:** Of the 39 HIV-1 transmissions observed, 28 were virologically linked to the infected partner (incidence rate, 0.9 per 100 person-years, 95% CI, 0.6-1.3). Of the 28 linked transmissions, 1 occurred in the early-therapy group (hazard ratio, 0.04; 95% CI, 0.01-0.27; P<0.001). **Conclusion:** Rates of HIV-1 transmission and clinical events were reduced by early initiation of antiretroviral therapy, suggesting personal and public health benefits.
Sepsis and Septic Shock		
CORTICUS	NEJM 2008;358:111-24	**Title:** Hydrocortisone Therapy for Patients With Septic Shock **Purpose:** To investigate the efficacy of hydrocortisone administration in patients with septic shock who were either responsive or unresponsive to corticotropin. **Methods:** 499 patients were randomly assigned to receive 50 mg IV hydrocortisone or placebo every 6 h for 5 d with dose tapering over the following 6 d. **Results:** No significant difference in mortality at 28 d between patients in groups that did not respond to corticotropin (39.2% in the hydrocortisone group and 36.1% in the placebo group, P=0.69) or between those that did response to corticotropin (28.8% and 28.7%, P=1.00). **Conclusion:** Survival was not improved by hydrocortisone in patients with septic shock.
Intensive Insulin Therapy and Pentastarch Resuscitation in Severe Sepsis. Brunkhorst et al. 2008	NEJM 2008;358:125-39	**Title:** Intensive Insulin Therapy and Pentastarch Resuscitation in Severe Sepsis **Purpose:** To investigate the role of intensive insulin therapy and the choice of either crystalloids or colloids in patients with severe sepsis. **Methods:** Patients received either intensive insulin therapy to maintain euglycemia or conventional insulin therapy and either 10% pentastarch or modified Ringer's lactate for fluid resuscitation. **Results:** Trial stopped for safety reasons. Intensive insulin therapy was associated with increased rates of hypoglycemia (17.0% vs. 4.1%, P<0.001) and serious adverse events (10.9% vs. 5.2%, P=0.01). Higher rates of acute renal failure and renal-replacement were seen in pentastarch as compared to Ringer's lactate. **Conclusion:** In critically ill patients with sepsis, intensive insulin therapy increased the risk of serious adverse events related to hypoglycemia. Pentastarch was harmful.
Bone and Joint Infections		
OVIVA	NEJM 2019;380:425-36	**Title:** Oral versus Intravenous Antibiotics for Bone and Joint Infection **Purpose:** To assess if oral antibiotics are noninferior to IV antibiotic treatment for managing complex orthopaedic infections. **Methods:** Within 1 wk post-surgery, 1054 patients were randomly assigned to receive IV or oral antibiotics for 6 wk. Both groups were permitted follow-on oral antibiotics. **Results:** There was no significant difference in risk of treatment failure between oral and IV groups (-1.4%; 95% CI, -5.6-2.9), indicating noninferiority. There was no significant difference in the rates of serious adverse events between groups. **Conclusion:** Oral antibiotics were noninferior to IV antibiotics for the treatment of complex orthopaedic infections when used for 6 wk.
DATIPO	NEJM 2021;384:1991-2001	**Title:** Antibiotic Therapy for 6 or 12 Weeks for Prosthetic Joint Infection **Purpose:** To identify the appropriate duration of antimicrobial therapy for the management of prosthetic joint infection. **Methods:** 410 patients with microbiologically confirmed prosthetic joint infection that had been managed with an appropriate surgical procedure were randomly assigned to receive either 6 wk or 12 wk of antibiotic therapy as soon as possible after surgery. **Results:** Rates of persistent infection were significantly higher in the 6-wk group as compared to the 12 wk group (18.1% vs. 9.4%; risk difference, 8.7%; 95% CI, 1.8%-15.6%). **Conclusion:** Antibiotic therapy for 6 wk was not noninferior to 12-wk therapy and resulted in more unfavourable outcomes in patients with prosthetic joint infections managed with standard surgical procedures.

Trial Name	Reference	Clinical Trial Details
Blood and Tissue Infections		
Seasonal Malaria Vaccination with or without Seasonal Malaria Chemoprevention. Zongo et al. 2021	NEJM 2021; 385:1005-1017	**Title:** Seasonal Malaria Vaccination with or without Seasonal Malaria Chemoprevention **Purpose:** The study compared the efficacy of RTS,S to that of SMC, which is the standard treatment for children in areas with highly seasonal malaria transmission. **Methods**: Randomly assigned 6861 children 5 to 17 mo of age to receive sulfadoxine-pyrimethamine and amodiaquine (2287 children [chemoprevention-alone group]), RTS,S/AS01E (2288 children [vaccine-alone group]), or chemoprevention and RTS,S/AS01E (2286 children [combination group]) **Results:** Demonstrated that not only is RTS,S comparable to SMC in preventing malaria, but that combining the two interventions is markedly superior to either intervention alone. **Conclusion:** Use of the two interventions together resulted in an approximately 70 percent further reduction in malaria deaths and hospitalizations, and a 60 percent reduction in uncomplicated malaria over use of SMC alone.
BENEFIT	NEJM 2015;373:1295-306	**Title:** Randomized Trial of Benznidazole for Chronic Chagas' Cardiomyopathy **Purpose:** To investigate the efficacy of trypanocidal therapy in patients with Chagas' cardiomyopathy. **Methods:** 2854 patients with Chagas' cardiomyopathy were randomly assigned to receive benznidazole or placebo for up to 80 d. **Results:** Rates of conversion to negative *Trypanosoma cruzi* PCR results were 66.2% in the benznidazole group and 33.5% in the placebo group at the end of treatment, 55.4% and 35.3% at 2 yr, and 46.7% and 33.1% at >5 yr (P<0.001 for all). PCR conversion rates did not correspond to clinical outcomes. **Conclusion:** In patients with Chagas' cardiomyopathy, trypanocidal therapy reduced serum parasite levels but did not improve cardiac deterioration.
Fungal Infections		
Voriconazole Versus Amphotericin B for Primary Therapy of Invasive Aspergillosis. Herbrecht et al. 2002	NEJM 2002;347:408-15	**Title:** Voriconazole Versus Amphotericin B for Primary Therapy of Invasive Aspergillosis **Purpose:** To compare voriconazole vs. amphotericin B for primary therapy of invasive aspergillosis. **Methods:** 277 patients randomly assigned to receive IV voriconazole followed by oral voriconazole BID or IV amphotericin B deoxycholate. **Results:** Successful outcomes occurred in 52.8% of patients on voriconazole and 31.6% on amphotericin B at wk 12 (absolute difference, 21.2%; 95% CI, 10.4-32.9). Rate of survival was 70.8% in the voriconazole group and 57.9% in the amphotericin B group (hazard ratio, 0.59; 95% CI, 0.40-0.88). Voriconazole was associated with significantly fewer severe adverse events. **Conclusion:** Initial therapy with voriconazole is more clinically effective with fewer side effects than the standard approach with amphotericin B.

Acronyms

CF	cystic fibrosis	GA	gestational age	MCADD	medium chain acyl-CoA dehydrogenase deficiency	NGS	next generation sequencing
CNV	copy number variant	GS	genome sequencing	MLPA	multiplex ligation-dependent probe assay	PKU	phenylketonuria
(W)ES	(whole) exome sequencing	GSD	glycogen storage disease	MSUD	maple syrup urine disease	SNP	single nucleotide polymorphism
(W)GS	(whole) genome sequencing	LCHAD	long chain 3-hydroxyacyl-CoA dehydrogenase deficiency			VLCAD	very long chain acyl-CoA dehydrogenase deficiency
FISH	fluorescence in situ hybridization						

Introduction to Genetics

Common Terms

- **penetrance**: probability that a gene variant is observably expressed in an individual who carries it
- **expressivity**: extent of gene expression – refers to the range of variation seen in a phenotype for a certain genotype
- **genetic heterogeneity**: when a phenotype/genetic disorder can be caused by different genotypes, due to genetic variation within the same gene (allelic heterogeneity) or in different genes (locus heterogeneity)
- **phenotypic heterogeneity**: pathogenic variants in the same gene result in multiple clinical manifestations and varying degrees of severity
- **mosaicism**: presence of two or more genotypes (e.g. chromosome patterns or gene variants) in the cells of the same person
- **nondisjunction**: a cell division error in which chromosomes fail to segregate, resulting in daughter cells with fewer or more chromosomes than expected
- **uniparental disomy**: inheritance of two full or partial copies of a chromosome from one parent and no corresponding full/partial chromosome from the other parent
- **allele**: an abnormal number of chromosomes in the cell due to loss or duplication

Genetic Variation

- a variant is a permanent change in the nucleotide sequence that differs from the most common nucleotide sequence (reference sequence)
- variants are classified based on their likelihood of disrupting the function of the gene product. The American College of Medical Genetics and Genomics has created a commonly used method for classifying variants for single gene disorders:
  - benign: not associated with genetic disease
  - likely benign: probably not associated with genetic disease, but insufficient evidence to classify as benign
  - variant of uncertain significance (VUS): insufficient evidence to classify variant as benign or pathogenic
  - likely pathogenic: 90% likely to be pathogenic, and clinically treated as a pathogenic variant
  - pathogenic: known to be associated with genetic disease
- nomenclature no longer used in clinical genetics:
  - mutation: previously synonymous with pathogenic variant. Now this term is only used to describe the actual process of genetic change
  - polymorphism: a variant that is relatively common in the population and not typically associated with a genetic disease. This term is used only in the context of population genetics

Types of Genetic Variation

- deletions or duplications of a whole gene(s) caused by aneuploidy, unbalanced chromosome rearrangements, or copy number variants (e.g. 22q11.2 deletion or DiGeorge syndrome; 17p11.2 duplication or Potocki-Lupski syndrome)
- disruption of a gene: inversions, balanced chromosome rearrangements
- variants that cause alteration in the protein coding sequence: missense (encodes for a different amino acid), nonsense (encodes for a premature stop codon), frameshift (deletion/insertion of a number of nucleotides that is not a multiple of 3, thus shifting the reading frame)
- variants that affect the transcription of a gene
- variants that affect splicing

Single Gene Disorders

- traits or disorders determined by variation occurring in a specific gene, which often follow a Mendelian inheritance pattern
- autosomal inheritance: disorder is caused by pathogenic variants in a gene located on chromosomes 1-22 (the autosomes)
  - autosomal dominant: one copy of a gene with a pathogenic variant is sufficient to cause a trait/disorder
  - autosomal recessive: both copies of a gene must have pathogenic variants to cause a trait/disorder; an individual with one copy of a pathogenic gene variant is a carrier
- sex-linked inheritance: when disease is caused by pathogenic variants in a gene on the X or the Y chromosome. Because the X chromosome contains more genes than the Y chromosome, almost all sex-linked traits are X-linked. X-linked inheritance generally results in a trait/disorder that is seen more commonly or with greater severity in males than females
  - e.g. Hemophilia A, Duchenne muscular dystrophy

Triplet Repeat Expansions

- disorders where the number of trinucleotide repeats in certain genes exceeds the normal number and results in altered gene expression or production of an abnormal protein
  - these disorders can demonstrate genetic anticipation, where signs and symptoms are more severe and appear at an earlier age from one generation to the next due to expansion of the triplet repeat number
  - length of expansion segment is often proportional to severity of clinical phenotype
- e.g. Fragile X syndrome, Huntington disease

Imprinting Disorders

- imprinted genes are expressed entirely from either the maternal or paternal allele, depending on the gene (parent-of-origin gene expression)
- imprinting is determined by allele-specific epigenetic mechanisms (i.e. modifications to DNA other than a change in the underlying sequence, such as DNA methylation and/or histone modifications)
- disorders occur when a pathogenic variant disrupts the normally expressed allele of an imprinted gene or through uniparental disomy of the normally silenced allele
- e.g. Prader-Willi syndrome, Angelman syndrome, Beckwith-Wiedemann syndrome

Mitochondrial Disorders

- disorders caused by pathogenic variants in mitochondrial DNA or in nuclear genes whose protein products are important for mitochondrial function
- high phenotypic heterogeneity
- mitochondrial disorders caused by pathogenic variants in nuclear genes demonstrate Mendelian inheritance (e.g. Alpers syndrome caused by autosomal recessive pathogenic variants in *POLG*)
- disorders caused by pathogenic variants in mitochondrial DNA are maternally inherited by all offspring as all mitochondria and associated mitochondrial DNA in the embryo comes from the maternal ovum, with no paternal contribution of mitochondria
- e.g. mitochondrial encephalomyopathy and lactic acidosis with stroke-like episodes syndrome (MELAS)

Common Indications for Genetic Referrals

- preconception and prenatal: abnormal prenatal screening test, fetal anomaly, recurrent pregnancy loss, personal or family history of a genetic condition, positive carrier screening test, consanguinity
- pediatric: major and/or multiple minor congenital anomalies, developmental delay, abnormal newborn screen, unusual growth pattern, abnormal pubertal development, connective tissue disorders, congenital hypo- or hypertonia
- adult: family history of adult-onset genetic condition (e.g. Huntington disease), personal or family history of cancer concerning for genetic cause, bleeding or clotting disorder, early onset vision or hearing loss, intellectual disability, leukodystrophies, muscular dystrophy, movement disorders (e.g. ataxia, dystonia, chorea), and metabolic diseases

Pedigrees

- diagrams of a family tree that show the pattern/distribution of phenotypes for a genetic disorder within that family, often across multiple generations
- pedigrees generally indicate sex assigned at birth, with or without genetic confirmation of sex chromosomes; when counselling gender diverse patients (including transgender and non-binary patients), physicians should affirm the patient's gender identity, while clarifying the role of sex assigned at birth or chromosomal sex in determining genetic features for the pedigree

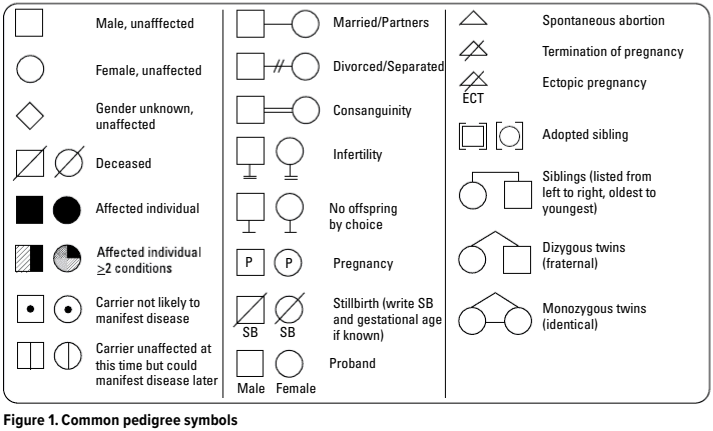

Figure 1. Common pedigree symbols

Meta-analysis of the Diagnostic and Clinical Utility of Genome and Exome Sequencing and Chromosomal Microarray in Children
Genomic Med 2018;3:16
Purpose: To compare the diagnostic and clinical utility of WGS and WES to that of chromosomal microarray.
Methods: A systematic review and meta-analysis of the literature.
Results: 37 studies were included (20068 children). Diagnostic utility of WGS (0.41, 95% CI 0.34-0.48) and WES (0.36, 95% CI 0.33-0.40) were greater than chromosomal microarray (0.10, 95% CI 0.08-0.12). The clinical utility of WGS (0.27, 95% CI 0.17-0.40) and WES (0.17, 95% CI 0.12-0.24) were higher than chromosomal microarray (0.06, 95% CI 0.05-0.07) and this difference was significant for WGS vs. chromosomal microarray (P<0.0001).
Conclusion: The diagnostic and clinical utility of WGS and WES is greater than that of chromosomal microarray.

Genetic Testing and Counselling

Common Terms

- presymptomatic genetic testing: used to determine whether individuals without current symptoms, but with a known family history of a genetic disease, carry the familial pathogenic variant associated with the disease
- newborn screening: performed within the first few days of life to detect treatable and potentially fatal disorders before symptoms arise to allow for early therapy
- preconception genetic counselling: pre-pregnancy evaluation to assess the risk of having a child with an inherited condition
- preimplantation genetic diagnosis: genetic testing of in vitro fertilized embryos for specific genetic conditions before uterine transfer

Table 1. Common Genetic Tests

Test	Karyotype	FISH	Microarray Analysis	Sanger Sequencing	NGS	MLPA	Repeat-Primed PCR
Technique	Microscopic analysis of chromosomes with a nucleic acid stain that shows large changes in the number or structure of chromosomes; can detect large CNVs	A fluorescent-tagged DNA probe used to identify a gain, loss, or rearrangement of chromosomal material or specific DNA sequence	A collection of DNA probes attached to a solid surface to which test DNA hybridize in order to determine copy number of DNA regions	A method of DNA sequencing which is based on the selective incorporation of chain-terminating nucleotides during replication	High-throughput method used to sequence multiple genes in parallel; NGS is the technology used for panel sequencing, (W)ES, and (W)GS	High-throughput multiplex PCR assay, which uses probes to evaluate the relative copy number of each DNA sequence	PCR amplification method which uses paired primers to generate different sized amplicons, due to multiple annealing sites on the template
Uses/Indications	Useful in identification of major aneuploidies, structural chromosomal rearrangements, chromosomal changes related to hematological conditions, or other genetic diseases related to chromosome structure	Can confirm the presence or absence of specific DNA sequences and localize them. It has good resolution for microdeletions and small translocations May be used to detect aneuploidies, perform gene mapping, identify oncogenes, and identify circulating tumour cells	Microarray analysis can identify small deletions or duplications of genetic material anywhere in the genome. Commonly indicated when there is developmental delay/ autism or two or more congenital anomalies	The "gold-standard" method for identification of single nucleotide variants in the gene(s) known to cause a suspected syndrome	Limited indications (vary by province) but may include: limit further invasive diagnostics and facilitate early intervention when there is multisystem involvement, or when the differential diagnosis includes ≥2 conditions that would require separate genetic tests	Can detect small copy number variants, at an exon-level resolution Widely used due to low cost, simplicity, and broad availability of commercially developed assays	Used to determine the number of repeats. Used in diagnostic or predictive testing in symptomatic or at-risk individuals

- see Obstetrics, OB7 for information on prenatal screening tests

Differences in Morphology

Congenital Anomalies

Minor and Major Anomalies

- minor anomaly: physical difference that is of no significant medical or cosmetic consequence to the patient (e.g. ear pit/tag, single palmar crease)
- major anomaly: physical difference that creates significant medical, surgical, or cosmetic problems for the patient (e.g. ventricular septal defect, cleft lip)

Mechanisms for Anomalies

- malformation: results from an intrinsically abnormal developmental process (e.g. polydactyly)
- disruption: results from the extrinsic breakdown of, or interference with, an originally normal developmental process (e.g. amniotic band disruption sequence)
- deformation: alteration of the final form of a structure by mechanical forces (e.g. Potter deformation sequence)
- dysplasia: abnormal development that results in abnormal organization of cells into tissues (e.g. skeletal dysplasia)

Multiple Anomalies

- association: non-random occurrence of multiple independent anomalies that appear together more often than would be predicted by chance, but are not known to have a single underlying etiology (e.g. VACTERL association)
- sequence: related anomalies that originate from a single initial major anomaly or precipitating factor that changes the development of other surrounding or related tissues or structures (e.g. Potter sequence or Pierre-Robin sequence)
- syndrome: a pattern of anomalies that occur together and are known or thought to have a single cause (e.g. CHARGE syndrome)

VACTERL Association
Vertebral dysgenesis
Anal atresia (imperforate anus) ± fistula
Cardiac anomalies
Tracheo**E**sophageal fistula ± esophageal atresia
Renal anomalies
Limb anomalies

Approach to the Patient with Physical Differences

Check the umbilical cord for 2 arteries and 1 vein. The presence of a single umbilical artery may be associated with other congenital anomalies

General Approach

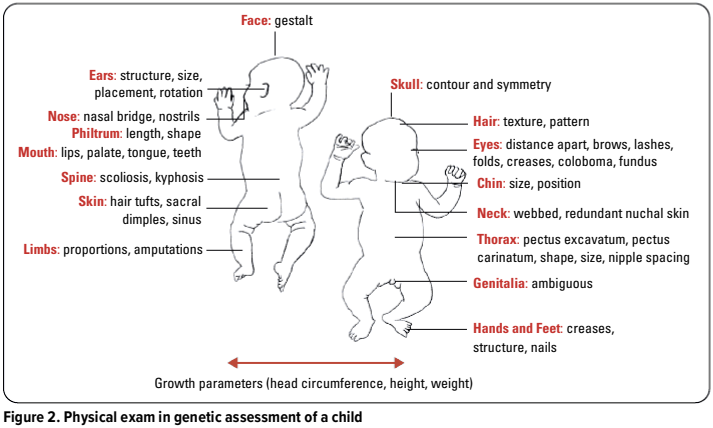
- are the anomalies major or minor?
- what is the mechanism underlying the anomaly?
- do the anomalies fit as part of an association, sequence, or syndrome?
- are the anomalies seen in other family members?

History

- prenatal/obstetrical history (see Obstetrics, OB4) with particular attention to potential teratogenic exposures, developmental history (see Pediatrics, P26), and past medical history
- complete three generation family pedigree: health history, consanguinity, multiple miscarriages/stillbirths, neonatal deaths, congenital defects, developmental delay/autism, ethnicity

Physical Exam

- compare features with other family members



Face: gestalt
Ears: structure, size, placement, rotation
Nose: nasal bridge, nostrils
Philtrum: length, shape
Mouth: lips, palate, tongue, teeth
Spine: scoliosis, kyphosis
Skin: hair tufts, sacral dimples, sinus
Limbs: proportions, amputations
Skull: contour and symmetry
Hair: texture, pattern
Eyes: distance apart, brows, lashes, folds, creases, coloboma, fundus
Chin: size, position
Neck: webbed, redundant nuchal skin
Thorax: pectus excavatum, pectus carinatum, shape, size, nipple spacing
Genitalia: ambiguous
Hands and Feet: creases, structure, nails
Growth parameters (head circumference, height, weight)

Figure 2. Physical exam in genetic assessment of a child

Investigations

- screening for TORCH infections (toxoplasmosis, syphilis, varicella-zoster, parvovirus B19, rubella, cytomegalovirus, herpes infection)
- serial photographs
- x-rays for bony abnormalities
- abdominal U/S and echocardiography to rule out structural abnormalities of organs
- brain imaging, especially if neurodevelopmental/neurological findings
- cytogenetic studies
  - chromosomal microarray analysis (SNP array) if developmental delay/autism or two or more congenital anomalies
  - FISH if aneuploidy syndrome (e.g. trisomy 13, 18, or 21) suspected
  - consider karyotype if a known aneuploidy syndrome is recognized or if there is a family history of a chromosomal rearrangement such as a translocation
- biochemistry: various biochemical tests, specific enzyme assays (e.g. for lysosomal storage diseases)
- single gene testing, gene panel testing, ES, GS
- sensory evaluations including audiology, ophthalmology or optometry

Management

- recurrence risk and prenatal counselling
- referral for specialized medical care or genetic care for symptomatic management
- patient education, connect to social and psychological support services

Genetic Conditions

Table 2. Common Chromosomal Aneuploidy Syndromes

	Trisomy 21	Trisomy 18	Trisomy 13
Disease	Down syndrome	Edwards syndrome	Patau syndrome
Incidence	1 in 600-800 births Most common abnormality of autosomal chromosomes Rises with advanced maternal age from 1 in 1500 at age 20 to 1 in 20 by age 45	1 in 6000 live births F:M=3:1	1 in 10000 live births
Cranium/Brain	Mild microcephaly, flat occiput, third fontanelle, brachycephaly	Microcephaly, prominent occiput	Microcephaly, sloping forehead, scalp defect, holoprosencephaly
Eyes	Upslanting palpebral fissures, epicanthal folds, speckled iris (Brushfield spots), refractive errors (myopia), acquired cataracts, nystagmus, strabismus	Microphthalmia, hypotelorism, iris coloboma, retinal anomalies	Microphthalmia, corneal abnormalities
Ears	Low-set, small, overfolded upper helix, frequent acute otitis media, hearing loss	Low-set, malformed	Low-set, malformed
Facial Features	Protruding tongue, large cheeks, low flat nasal bridge, small nose	Cleft lip/palate Small mouth, micrognathia	60-80% cleft lip and palate
Musculoskeletal (MSK)	Short stature Excess nuchal skin Joint hyperflexibility (80%) including dysplastic hips, vertebral anomalies, atlantoaxial instability	Intrauterine growth restriction Clenched fist with overlapping digits, hypoplastic nails, clinodactyly	Small head size Polydactyly
Cardiac Defect	50% (particularly atrioventricular septal defect)	60% (ventricular septal defect, patent ductus arteriosus, atrial septal defect)	80% (atrial septal defect, patent ductus arteriosus, ventricular septal defect)
Gastrointestinal (GI)	Duodenal/esophageal/anal atresia, tracheoesophageal fistula, Hirschsprung's disease, chronic constipation	Hernia, tracheoesophageal fistula	None known
Genitourinary (GU)	Cryptorchidism, rarely fertile	Polycystic kidneys, cryptorchidism	Polycystic kidneys
Central Nervous System (CNS)	Hypotonia at birth Low IQ, developmental delay, hearing problems Onset of Alzheimer's disease in 40s	Hypertonia	Hypo- or hypertonia Seizures, deafness
Other Features	Single transverse palmar crease, clinodactyly, and absent middle phalanx of the 5th finger 1% lifetime risk of leukemia Polycythemia Hypothyroidism	Small for GA Rocker-bottom feet	Single umbilical artery Midline anomalies: scalp, holoprosencephaly, palate, heart, umbilicus, anus
Prognosis/Management	78% 1 yr survival for patients with congenital heart defect, 96% 1yr survival for patients without anomalies Long-term management per AAP Guidelines: Health Supervision of Children with Down Syndrome	13% 1 yr survival, 10% 10 yr survival Profound intellectual disability in survivors	20% 1 yr survival, 13% 10 yr survival Profound intellectual disability in survivors

Table 3. Common Genetic Disorders Involving the Sex Chromosomes

	Fragile X Syndrome	Klinefelter Syndrome	Turner Syndrome
Genotype	CGG trinucleotide repeat expansion in *FMR1* gene on X chromosome; ~55-~200 repeats is considered a premutation, whereas >200 repeats is considered a full mutation	47,XXY (most common) 48,XXXY, 49,XXXXY	45,X0 (50% of cases), 45,X/46,XX mosaic (15% of cases)
Incidence	1 in 3600 males, 1 in 6000 females Most common heritable cause of intellectual disability in males	1 in 1000 live male births Increased risk with advanced maternal age	1 in 2000-2500 live female births No increased risk with advanced maternal age
Phenotype	Overgrowth: macrocephaly, prominent jaw, forehead, and nasal bridge with long and thin face, large protuberant ears, macroorchidism, hyperextensibility, and high arched palate Complications: seizures, scoliosis, mitral valve prolapse Premutation carriers (males more often than females) may demonstrate tremor/ataxia syndrome in later life Female permutation carriers have a higher probability of having a child with FXS, because repeats in the permutation range are more likely to expand to pathogenic repeat length	Tall, slim, underweight No features pre-puberty Post-puberty: variable learning/behavioural difficulties, long limbs, gynecomastia, lack of facial hair	Short stature, short webbed neck, low posterior hairline, wide carrying angle Broad chest, widely spaced nipples Lymphedema of hands and/or feet, cystic hygroma in newborn with polyhydramnios, lung hypoplasia Coarctation of aorta, bicuspid aortic valve Renal and cardiovascular abnormalities, increased risk of hypertension Less severe spectrum with mosaic
IQ and Behaviour	Mild to moderate intellectual disability, 20% of affected males have normal IQ Attention deficit hyperactivity disorder (ADHD) and/or autism Females with full mutation may show milder intellectual impairment Premutation carriers have a normal IQ	Mild intellectual disability or learning difficulties Behavioural or psychiatric disorders: anxiety, shyness, aggressive, and impulsive behaviour acts	Typically normal intelligence
Gonad and Reproductive Function	Premutation carrier females at risk of developing premature ovarian failure	Infertility due to hypergonadotropic hypogonadism	Streak ovaries with deficient follicles, infertility, primary amenorrhea, impaired development of secondary sexual characteristics
Diagnosis	Molecular testing of *FMR1* gene: PCR and/or Southern blot analysis of trinucleotide repeat length, methylation analysis	Karyotype	Karyotype

Table 4. Examples of Other Genetic Syndromes

	22q11.2 Deletion Syndrome (DiGeorge syndrome)	Prader-Willi Syndrome	Angelman Syndrome	Noonan Syndrome	CHARGE Syndrome
Genotype	Autosomal dominant; microdeletions of chromosome region 22q11.2	Lack of gene expression on paternal chromosome 15q11-13 due to deletion, maternal uniparental disomy of chromosome 15, or imprinting defect	Lack of gene expression on maternal chromosome 15q11-13 due to deletion, paternal uniparental disomy of chromosome 15, or an imprinting defect Rarely due to pathogenic variants in *UBE3A*	Autosomal dominant with variable expression, pathogenic variants in RAS/MAPK pathway genes ("RASopathies"); autosomal recessive with pathogenic variants in *LZTR1*	2/3 of children with CHARGE have been found to have a pathogenic variant in *CHD7*
Incidence	1 in 4000; second most common genetic diagnosis (next to Down syndrome)	1 in 15000	1 in 10000	1 in 2000	1 in 10000
Clinical Features	**"CATCH 22"** **C**yanotic suggesting congenital heart disease (CHD) **A**nomalies: craniofacial anomalies, micrognathia, and low set ears **T**hymic hypoplasia: immunodeficiency **C**ognitive impairment **H**ypoparathyroidism, hypocalcemia **22**q11 microdeletions High-risk for schizophrenia and other psychiatric disorders	**"H3O"** **H**ypotonia and weakness **H**ypogonadism, obsessive **H**yperphagia **O**besity Short stature, almond-shaped eyes, small hands and feet with tapering of fingers Hypopigmentation, T2DM	Ataxia with severe intellectual disability, seizures, tremulousness, midface hypoplasia, large mouth, fair hair, inappropriately happy demeanour/laughter, fascination with water	Short stature, webbed neck, hypertelorism, low-set ears, epicanthal folds, ptosis, pectus excavatum Right-sided CHD, pulmonary stenosis Increased risk of hematological cancers, cardiomyopathy, moderate intellectual disability, delayed puberty	**"CHARGE"** **C**oloboma **H**eart disease **A**tresia of choanae **R**estriction of growth and mental development **G**U anomalies **E**ar malformations and hearing loss

Table 5. Examples of Familial Cancer Syndromes

Syndrome	Gene	Associated Cancers	Screening and Monitoring
Li-Fraumeni Syndrome	*TP53*	Breast, osteosarcoma, leukemia, soft tissue sarcoma, brain, adrenocortical carcinoma, and numerous other cancers	**Children:** From birth: abdominal/pelvic U/S every 3-4 mo; annual brain MRI and whole-body MRI, if with high-risk TP53 variant **Adults:** Women age 20-75: annual breast MRI Age 18: annual dermatologic examination, abdominal/pelvic U/S, brain MRI, and WBMRI Age 25: colonoscopy and upper endoscopy every 2-5 yr *(Moderate recommendation)*
Lynch Syndrome (HNPCC)	*MSH2, MLH1, MSH6, PMS2, EPCAM*	Colorectal, endometrial, ovarian, renal, pancreatic, liver/biliary duct, stomach, brain, breast	Age 20-25 (or 2-5 yr younger than earliest age of colorectal cancer diagnosis in family): colonoscopy every 1-2 yr Age 30 yr (*MSH6*) and 35 (*PMS2*): colonoscopy every 1-2 yr *(Strong recommendation)*
Familial Adenomatous Polyposis (FAP)	*APC*	Colorectal, small intestine/stomach tumours	Age 10: sigmoidoscopy or colonoscopy every 1-2 yr, colonoscopy once polyps develop *(Strong recommendation)*
Hereditary Breast and Ovarian Cancer Syndrome	*BRCA1, BRCA2*	Female: breast, ovarian, pancreatic Male: prostate, breast, pancreatic	Age 25-65: annual breast MRI Age 30: annual breast MRI and mammograms *(Strong recommendation)*
Von Hippel-Lindau Syndrome	*VHL*	Hemangioblastomas of the brain, spinal cord, and retina; renal cell carcinoma; pheochromocytoma; kidney cysts; pancreatic neuroendocrine tumour; and endolymphatic sac tumour	Age 2: annual physical examination, annual ophthalmologic examination, consider annual catecholamine assessment Consider baseline audiometry at age of school entry Ages 12, 15, and 18: MRI of brain stem, spine, and abdomen, with abdominal U/S in alternating years Age 20: MRI every 2 yr *(Expert opinion)*
Cowden Syndrome	*PTEN*	Breast, thyroid, endometrial	Women: Age 30 (or 5-10 yr before earliest breast cancer in the family): annual mammography Age 30: consider random annual endometrial biopsy and/or U/S Men and Women: At diagnosis: annual thyroid U/S Children: evaluation for neurodevelopmental disorders Age 18: annual comprehensive physical exam Age 30-35: colonoscopy every 5 yr *(Moderate recommendation)*
Neurofibromatosis (NF)			
Type 1	*NF1*	Astrocytoma, optic glioma, neurofibroma, leukemia	Children: evaluation for neurodevelopmental disorders Annual physical exam including evaluation of growth, blood pressure, skin examination, bone examination, neurological examination, and vision screening *(Expert opinion)*
Type 2	*NF2*	Vestibular schwannoma, meningioma, ependymoma, astrocytoma	Annual physical exam including audiology assessment Age 10: annual brain MRI, spinal MRI every 2-3 yr *(Expert opinion)*

Table 6. Examples of Heritable Connective Tissue Disorders

	Loeys-Dietz Syndrome	Classical Ehlers-Danlos Syndrome	Vascular Ehlers-Danlos Syndrome	Marfan Syndrome
Inheritance	Autosomal dominant	Autosomal dominant	Autosomal dominant	Autosomal dominant
Pathophysiology	Pathogenic variants in *TGFBR1, TGFBR2, SMAD3, TGFB2* genes affecting the TGF-β pathway	Pathogenic variants in *COL5A1* or *COL5A2* genes affecting Type V collagen	Pathogenic variants in *COL3A1* gene that affect Type III collagen, which is most abundant type of collagen in aortic extracellular matrix	Pathogenic variants in *FBN1* gene
Incidence	Unknown	1 in 20000-40000	1 in 100000-250000	1 in 3000-5000
Clinical Features	Vascular findings (aortic aneurysms and dissections, generalized arterial tortuosity), craniofacial features (cleft palate, hypertelorism), skeletal features, easy bruising, allergic/inflammatory disease	Clinical features vary: generalized joint hypermobility, skin hyperextensibility and atrophic scarring, fragile skin, easy bruising, subcutaneous spheroids (fat cysts) on forearms and shins	Arterial fragility and/or rupture, aortic dilatation, intestinal rupture, uterine rupture in pregnancy, characteristic facies (translucent skin, thin lips, pinched nose, prominent ears)	Tall and slender build, disproportionately long limbs and digits, aortic dilatation, lens detachment, pneumothoraces

Table 7. Examples of Intracellular/Extracellular Transport Receptor Disorders

	Hereditary Hemochromatosis	Wilson Disease	CF
Inheritance	Autosomal recessive	Autosomal recessive	Autosomal recessive
Pathophysiology	Pathogenic variants in *HFE* gene (rarely *HJV, HAMP, TFR2*, and *SLC40A1* genes), disrupting regulation of iron	Pathogenic variants in *ATP7B* gene, leading to the impairment of cellular copper transport	Pathogenic variants in *CFTR* gene, which predominantly affects the lungs, but also the GI tract
Incidence	1 in 300	1 in 30000	1 in 3200-15000
Clinical Features	Iron overload (elevated transferrin saturation and ferritin), bronze skin, arthralgia, hormone disturbance (DM, hypogonadism), cirrhosis, cardiomyopathy	Liver disease (acute and/or chronic), movement disorders, psychiatric disturbance, Kayser-Fleischer rings	Severe to mild: Malabsorption, failure to thrive, pancreatic insufficiency Bronchiectasis, male infertility More information found in other chapters*
Management	Phlebotomy for elevated serum ferritin and transferrin saturation	Chelating agents (e.g. penicillamine, trientine)	More information found in other chapters*

*See Respirology, R12 and Pediatrics, P92

Other Single Gene Disorders

SICKLE CELL DISEASE

- autosomal recessive disease caused by pathogenic variants in the HBB gene, resulting in the production of an abnormal version of β-globin and subsequently distorted red blood cells
- see Hematology, H21

DUCHENNE MUSCULAR DYSTROPHY

Incidence

- 1 in 4000 males

Etiology

- one type of muscular dystrophy characterized by progressive skeletal and cardiac muscle degeneration
- X-linked recessive: 1/3 de novo pathogenic variants, 2/3 inherited pathogenic variants
- missing structural protein (dystrophin) → muscle fibre fragility → fibre breakdown → necrosis and degeneration

Clinical Features

- proximal muscle weakness by age 3, positive Gowers' sign, waddling gait, toe walking
- pseudohypertrophy of calf muscles (muscle replaced by fat) and wasting of thigh muscles
- decreased reflexes
- non-progressive delayed motor and cognitive development (dysfunctional dystrophin in brain)
- cardiomyopathy

Diagnosis

- molecular genetic studies of dystrophin gene (*DMD*) (first line)
- genotype-phenotype correlations: different variants in the gene will cause some dystrophin production and a milder muscular dystrophy, Becker muscular dystrophy
- family history (pedigree analysis demonstrating X-linked inheritance)
- increased creatine kinase (50-100x normal) and lactate dehydrogenase
- muscle biopsy, EMG

See Landmark Medical Genetics Trials table for more information on the C-type natriuretic peptide analogue therapy (vosoritide) RCT, which assesses the safety and efficacy of vosoritide in the treatment of achondroplasia in children

Gene Therapy for Spinal Muscular Atrophy (SMA): A Review of Current Challenges and Safety Considerations for Onasemnogene Abeparvovec (Zolgensma)
Cureus 2023;15(3):e36197
Purpose: To review the safety, efficacy, and current challenges of the gene therapy onasemnogene abeparvovec (Zolgensma) in the treatment of the autosomal recessive disorder SMA.
Methods: Narrative literature review of PubMed, MEDLINE, and Ovid databases for articles that provided pertinent information about Zolgensma as a gene therapy for SMA.
Results: 10 articles met the inclusion criteria. There is evidence that Zolgensma is an efficacious therapy for SMA type 1 (the most severe form of the disorder), especially when administered to patients under 3 months of age. Hepatotoxicity is a major concern, but can be managed through close monitoring of liver enzyme levels and prophylactic medications. Zolgensma is more cost-effective than comparable therapies.
Conclusion: Due to its effectiveness, safety profile, and cost, Zolgensma is a good treatment option for SMA type 1. More data is needed to evaluate long-term risks and benefits.

See Landmark Medical Genetics Trials table for more information on the FLAURA trial, which compares Osimertinib against other EGFR inhibitors in patients with EGFR positive NSCLC

Corticosteroids for the Treatment of Duchenne Muscular Dystrophy (DMD)
Cochrane DB Syst Rev 2016;5:CD003725
Purpose: To assess the effects of corticosteroids on prolongation of walking ability, muscle strength, functional ability, and quality of life in DMD and address whether benefit is maintained over long term, assess adverse events, and compare efficacy of different regimens.
Methods: Systematic review including RCTs or quasi-RCTs of corticosteroids given to patients with definitive DMD diagnosis for at least 3 mo.
Results: 12 studies with 667 participants included. Meta-analyses showed that corticosteroids improved muscle strength and function vs. placebo over 6 mo. Evidence from single trials showed 0.75 mg/kg/d superior to 0.3 mg/kg/d on most strength and function measures, with little evidence of further benefit at 1.5 mg/kg/d. Improvements were seen in time taken to rise from the floor, timed walk, four-stair climbing time, ability to lift weights, leg function grade, and forced vital capacity. Moderate quality evidence of adverse effects: excessive weight gain, behavioural abnormalities, cushingoid appearance, and excessive hair growth.
Conclusions: Moderate quality evidence from RCTs indicates that corticosteroid therapy in DMD improves muscle strength and function in the short term (12 mo), and strength (up to 2 yr.) Dose of 0.75 mg/kg/d should be enough. Adverse effects were common but not clinically severe.

Gowers' Sign
Child uses hands to "climb up" the legs to move from a sitting to a standing position. Observed in individuals with weakness of the pelvic and proximal lower limb muscles

Management
- supportive (e.g. physiotherapy, wheelchairs, braces); prevent obesity
- cardiac health monitoring and early intervention (annually if male, every 3-5 years if female)
- bone health monitoring and intervention (vitamin D, bisphosphonates), at baseline and annually
- steroids (e.g. prednisone or deflazacort)
- surgical (for scoliosis)
- gene therapy trials underway

Complications
- patient usually wheelchair-bound by age 12
- early flexion contractures, scoliosis, osteopenia of immobility, increased risk of fracture
- death due to pneumonia/respiratory failure or CHF in second-third decade

Genetic and Metabolic Investigations for Neurodevelopmental Disorders: Position Statement of the Canadian College of Medical Geneticists (CCMG)
J Med Genet 2023;jmg-2022-108962
Purpose: To provide recommendations for genetic and metabolic investigations for patients with neurodevelopmental disorders (NDD), specifically, patients with global developmental delay (GDD), intellectual disability (ID), and/or autism spectrum disorder (ASD).
Methods: A multidisciplinary group, composed of physicians and clinical scientists, reviewed existing literature and guidelines. Evidence was synthesized and circulated to the CCMG and Canadian Pediatric Society for feedback.
Recommendations:
- chromosomal microarray for patients with GDD, ID, or ASD (first-tier test)
- Fragile X testing for patient with suggestive clinical features or family history (first-tier test)
- metabolic investigations for patients with clinical features suggestive of an inherited metabolic disease
- exome sequencing and comprehensive gene panel for patients with GDD or ID (second-tier test)
- genetic testing is not recommended for patients with NDD in absence of GDD, ID, or ASD, unless accompanied by clinical features suggestive of a syndromic etiology or inherited metabolic disease

Metabolic Diseases

- individually rare but collectively occur in 1 in 1500 births
- inherited disorders of metabolism; most are autosomal recessive
- infants and older children may present with failure to thrive or developmental delay
- organelle disorders can present with dysmorphism
- universal newborn screening in Ontario, Canada includes some treatable metabolic disorders

Table 8. Metabolic Disorders

	Protein Metabolism Disorders	Carbohydrate Disorders	Fatty Acid Disorders	Organelle Disorders
Examples of Conditions	PKU* Tyrosinemia* Homocystinuria* MSUD* Alkaptonuria Propionic acidemia* Urea cycle defects (Ornithine transcarbamylase deficiency)	Galactosemia* GSDs: von Gierke, Pompe, Cori, Andersen, McArdle	MCADD* VLCAD* LCHAD*	Congenital disorders of glycosylation Lysosomal storage diseases: mucopolysaccharidosis (Hunter, Hurler*), Niemann-Pick, Tay-Sachs, Gaucher, Fabry, Krabbe Peroxisomal defects: Zellweger syndrome, X-linked adrenoleukodystrophy
Clinical Manifestations	Coma, irritability, lethargy, poor feeding Seizures Intellectual disability Vomiting and acidosis after feeding initiation Sweet-smelling urine (MSUD)	Hypoglycemia, hepatomegaly, liver failure, cardiomyopathy Growth retardation, failure to thrive	Lethargy, poor feeding Seizures, coma Symptoms triggered by fasting Liver dysfunction Sudden infant death	Progressive neurological problems Developmental regression Chronic encephalopathy Developmental delay Bone crises (Gaucher) Deafness, blindness
Laboratory Findings	Hyperammonemia with normal anion gap (urea cycle defects), hyperammonemia with high anion gap (organic acidemia)	Elevated liver enzymes (galactosemia) Hypoglycemia lactic acidosis hyperlipidemia (GSD)	Hypoketotic hypoglycemia Elevated free fatty acids Elevated creatine phosphokinase	Elevated urine oligosaccharides (oligosaccharidoses) and glycosaminoglycans (mucopolysaccharidoses), abnormal transferrin isoelectric focusing (congenital disorders of glycosylation), abnormal very long chain fatty acids (peroxisomal defects)
Physical Exam	Hypotonia/hypertonia Microcephaly, musty odour, eczema, hypopigmentation (PKU) Dark urine, pigmented sclerae, arthralgias (alkaptonuria) Lens subluxation, Marfanoid appearance (homocystinuria)	Infantile cataracts (galactosemia) Hepatomegaly Muscle weakness/cramping	Hepatomegaly Hypotonia	Dysmorphic facial features Macrocephaly (Lysosomal storage diseases) Hepatosplenomegaly (Niemann-Pick type A/B/C, not Tay-Sachs) Cherry-red spot on macula (Niemann-Pick type A/B, Tay-Sachs, Gaucher) Corneal clouding (Hurler) Infantile cataract (Fabry) Peripheral neuropathy (Fabry, Krabbe) Spasticity

* Metabolic disorders included in Newborn Screening Ontario

Initial Investigations for a Child with Acute Problems Thought to be Due to an Inborn Error of Metabolism
- important to send lab studies at initial presentation in order to facilitate immediate diagnosis and treatment
- check newborn screening results
- electrolytes, arterial blood gases (calculate anion gap, rule out acidosis)
- CBC with differential and smear
- blood glucose (hypoglycemia seen with organic acidemia, fatty acid oxidation defects, and GSDs)
- lactate, ammonium (hyperammonemia with urea cycle defects or organic acidemias), plasma Ca^{2+} and Mg^{2+}, plasma amino acid screen
- routine U/A: ketonuria must be investigated in a neonate, urinary organic acids
- carnitine levels with acylcarnitine profile
- others: urate, urine nitroprusside, CSF glycine, free fatty acids (3-β-hydroxybutyrate ratio >4 in fatty acid oxidation defect)

See Landmark Medical Genetics Trials table for more information on the use of Elexacaftor/Tezacaftor/Ivacaftor in children with F508del cystic fibrosis

See Landmark Medical Genetics Trials table for more information on the efficacy and safety of a low-phenylalanine diet in combination with phenylketonuria medical foods or traditional amino acid medical foods in individuals with PKU

Treatment

- varies according to inborn error of metabolism but includes dietary restrictions, toxic metabolite sequestrants, enzyme replacement, etc.
- in the presentation of acute decompensation potentially caused by an inborn error of metabolism, discontinue feeding to prevent further buildup of toxic metabolites

See Landmark Medical Genetics Trials table for more information on the PRISM trial, which evaluates the safety and efficacy of pegvaliase treatment in adults with PKU

Table 9. Presentation and Management of Select Metabolic Disorders

	Phenylketonuria (PKU)	Galactosemia	Maple Syrup Urine Disease (MSUD)	Glycogen Storage Disease (GSD) Type 1 (Von Gierke Disease)	Tay-Sachs Disease	Ornithine Transcarbamylase (OTC) Deficiency
Inheritance and Incidence	1 in 10000; autosomal recessive disease (mutations in *PAH* gene)	1 in 60000; autosomal recessive disease	1 in 185000; autosomal recessive disease (pathogenic variants in *BCKDHA*, *BCKDHB*, and *DBT* genes), 1 in 25000 in Ashkenazi Jewish, 1 in 400 in Mennonites	1 in 100000; autosomal recessive disease, 1 in 20000 in Ashkenazi Jewish	1 in 320000; autosomal recessive disease, 1 in 3600 in Ashkenazi Jewish	1 in 62000 to 77000; X-linked condition
Pathophysiology	Deficiency of phenylalanine hydroxylase prevents conversion of phenylalanine to tyrosine leading to buildup of phenylalanine and its toxic metabolites Mothers who have PKU may have infants with multiple congenital abnormalities	Most commonly due to deficiency of galactose-1-phosphate uridyltransferase leading to an inability to process lactose/galactose	Reduction or elimination of protein complex needed for amino acids leucine, isoleucine, and valine breakdown, leading to toxic build-up	Pathogenic variants in *G6PC* (cause of GSD1a) and *SLC37A4* (cause of GSD1b) genes prevent effective conversion of glucose-6-phosphate to glucose. Glucose-6-phosphate is converted to glycogen and fat which subsequently accumulate in cells, especially in the liver and kidneys	Pathogenic variants in the *HEXA* gene, which encodes alpha subunit of hexosaminidase A; leads to intracellular accumulation of GM2 ganglioside, lysosome dysfunction, and neurodegeneration	Pathogenic variants in the OTC gene, which is localised on the X-chromosome. It encodes an enzyme required for the urea cycle and its dysfunction leads to accumulation of ammonia
Clinical Features	Baby is normal at birth, then develops a musty odour, eczema, hypertonia, tremors, and intellectual disability. Hypopigmentation due to low tyrosine levels (fair hair, blue irises)	Signs of liver and renal failure, jaundice, failure to thrive, and cataracts with ingestion of lactose/galactose Complications: Increased risk of sepsis, especially *E. coli* If the diagnosis is not made at birth, liver and brain damage may become irreversible	Feeding intolerance, failure to thrive, vomiting, lethargy, and maple syrup odour in urine and cerumen May progress to irreversible intellectual disability, hyperactivity, severe failure to thrive, seizures, coma, cerebral edema, and death if inadequately treated	Typically presents between 3-6 mo of age with hepatomegaly, hypoglycemia, poor fasting tolerance, growth failure, and "doll-like" facies (full cheeks with thin extremities) Complications: Lactic acidosis, hyperuricemia, hyperlipidemia, delayed puberty, renal disease, hypoglycemic seizures, hepatic adenomas, osteoporosis	Various presentations: infantile form (onset at 3-6 mo), juvenile form (onset at 2-6 yr), and adult or chronic form (onset at >10 yr) Psychomotor regression, hypotonia, increased startle response, macular cherry red spot, seizures, and hearing impairment	Neonatal onset (male presentation is typically more severe than female presentation): infants appear well at birth, and develop reduced oral intake and lethargy, progressing into tachypnea, hypothermia, severe encephalopathy and a coma Late onset forms: may present at any time and have precipitating event (fasting, illness, protein overload). Lethargy, episodic vomiting, and headaches Complications: seizures, encephalopathy, acute liver failure and a coma
Diagnosis and Management	PKU screening at birth Life-long dietary restriction of phenylalanine starting within the first 10 d of life; especially important during pregnancy to maintain normal phenylalanine levels to prevent maternal PKU effects on fetus Large neutral amino acid (tyrosine) replacement, BH4 enzyme treatment, phenylalanine lyase treatment are other options	Screened for in many newborn screening programs but generally present with liver failure and E. coli sepsis before screening result reported Elimination of galactose from the diet (e.g. dairy, breast milk) Most infants are fed a soy-based diet	MSUD is screened in most newborn screening programs. Serum amino acid evaluation (leucine, isoleucine, alloisoleucine, and valine) and urine organic acid analysis Protein-restricted, high-carbohydrate diet to limit branched amino acid intake A trial of thiamine therapy in addition may be recommended for some infants	Hypoglycemia when interval between feeds are increased (>3-4 h), lactic acidemia, hypertriglyceridemia, and hepatomegaly Treat with nutrition therapy (small frequent feedings, avoid fructose/sucrose/galactose), continuous overnight feedings, raw cornstarch (for slow, sustained glucose release), vitamin supplementation, frequent blood glucose monitoring	Clinical suspicion β-Hexosaminidase enzyme activity (serum) Ashkenazi Jewish carriers often identified by preconception screening Treatment is supportive	Suspect OTCD in patients with hyperammonemia and high urinary orotic acid. Enzyme analysis and/or genetic testing can confirm. Treat with calories (typically 10% dextrose solution at 1.5x maintenance fluids), IV arginine, IV ammonium scavengers (combination of sodium benzoate and sodium phenylbutyrate). Hemodialysis if ammonia >500 umol/L. Long-term: protein restriction supplemented with essential amino acids, citrulline, and ammonia scavengers

See Landmark Medical Genetics Trials table for more information on the SONIA-2 trial, which investigates the efficacy, safety and clinical benefit of nitisinone in the treatment of alkaptonuria

Landmark Medical Genetics Trials

Trial Name	Reference	Clinical Trial Details
PHENYLKETONURIA		
Glycomacropeptide for Nutritional Management of Phenylketonuria: A Randomized, Controlled, Crossover Trial	Am J Clin Nutr 2016; 104(2):334-345	**Title**: Glycomacropeptide for Nutritional Management of Phenylketonuria: A Randomized, Controlled, Crossover Trial **Purpose**: To evaluate the efficacy and safety of a low-phenylalanine (Phe) diet in combination with either glycomacropeptide medical foods (GMP-MFs) or traditional amino acid medical foods (AA-MFs) in individuals with phenylketonuria (PKU). **Methods**: Thirty early-treated individuals aged 15-49 yr with PKU participated in a 2-stage, randomized crossover trial involving consumption of a low-Phe diet with AA-MFs or GMP-MFs for periods of 3 wk each. **Results**: Dietary management of PKU with GMP-MFs compared to AA-MFs resulted in higher intake among participants. GMP-MFs were rated as more acceptable in terms of taste and had less side effects. **Conclusions**: GMP-MFs are safe for dietary management of PKU. GMP-MFs may improve dietary adherence for patients with PKU.
PRISM	Mol Genet Metab 2018; 124(1):27-38	**Title**: Pegvaliase for the Treatment of Phenylketonuria: Results of a Long-Term Phase 3 Clinical Trial Program (PRISM) **Purpose**: Evaluate the efficacy and safety of pegvaliase treatment in adults with phenylketonuria (PKU). **Methods**: Pegvaliase-naive participants with blood Phe >600 µmol/L were randomized to receive 20 mg/d or 40 mg/d of pegvaliase. **Results**: Pegvaliase treatment was given to 261 participants. Within 24 mo, 68.4% of participants achieved blood Phe ≤600 µmol/L. Reductions in blood Phe were associated with neuropsychiatric outcomes, which were maintained with long-term treatment. The vast majority of adverse events (99%) were mild or moderate in severity. **Conclusions**: Results from this trial suggest pegvaliase is safe and efficacious in treating adults with PKU.
CYSTIC FIBROSIS		
Study of Elexacaftor/Tezacaftor/Ivacaftor in Children 6 through 11 Years of Age with Cystic Fibrosis and at Least One F508del Allele	Am J Respir Crit Care Med 2021;203(12):1522	**Title**: Study of Elexacaftor/Tezacaftor/Ivacaftor in Children 6 through 11 Years of Age with Cystic Fibrosis and at Least One F508del Allele **Purpose**: Elexacaftor/tezacaftor/ivacaftor as a combination therapy was effective in treating patients aged greater than 12 years with CF and an accompanying F508del. This 24-week study served to evaluate the efficacy of treatment in patients less than <12 yr. **Methods**: RCT consisting of 66 children aged between 6 and 11 with CF who were assessed for the primary outcome of interest being safety and tolerability of the proposed treatment of oral Elexacaftor 100 mg once daily, Tezacaftor 50 mg once daily, and Ivacaftor 75 mg q12 h for children weighing ≤30 kg and oral Elexacaftor 200 mg once daily, Tezacaftor 100 mg once daily, and Ivacaftor 150 mg q 12 h for children weighing ≤30 kg. Additionally, efficacy of the treatment was also assessed (FEV_1, and Cystic Fibrosis Questionnaire–Revised respiratory domain score). **Results**: Commonly reported side effects included cough, headache, and fever. Treatment also resulted in improvements in predicted FEV_1 (10% improvement), and Cystic Fibrosis Questionnaire-Revised respiratory domain score (7.0 points improvement). **Conclusion**: Results show that treatment of CF with accompanying F508del using Elexacaftor/Tezacaftor/Ivacaftor resulted in significant improvements in patients aged under 12.
NON-SMALL CELL LUNG CANCER		
FLAURA	N Engl J Med 2018; 378(2):113-125	**Title**: Osimertinib in Untreated EGFR-Mutated Advanced Non-Small-Cell Lung Cancer (NSCLC) **Purpose**: To compare Osimertinib (a third-generation EGFR inhibitor) against existing standard EGFR inhibitors in patients with previously untreated EGFR mutation-positive NSCLC **Methods**: Double-blind, RCT consisting of 556 previously untreated EGFR mutation positive NSCLC patients. Patients were randomized to receive osimertinib or a standard EGFR-TKI. Outcome of interest included clinician-assessed progression-free survival. **Results**: Median progression-free survival was greater in osimertinib when compared to standard EGFR-TKIs in EGFR mutation positive NSCLC patients (18.9 mo vs. 10.2 mo). **Conclusion**: Results of this study show that osimertinib had superior efficacy when compared to standard EGFR-TKIs.
ALKAPTONURIA		
SONIA-2	Lancet Diabetes Endocrinol. 2020 Sep;8(9):762-772	**Title**: Using Once-Daily Nitisinone for Treatment of Alkaptonuria **Purpose**: No homogentisic acid (HGA) lowering medications have been for treatment of Alkaptonuria. **Methods**: RCT consisting of 138 patients aged 25 or older with confirmed alkaptonuria were randomized to receive either oral nitisinone 10 mg daily or no treatment. The outcome of interest was daily urinary HGA excretion (u-HGA24) after 12 mo. **Results**: 55 patients in the nitisinone group and 53 in the control group completed the study. u-HGA24 at 12 mo was significantly decreased by 99·7% in the nitisinone group compared with the control group. Conclusion: Nitisinone was well tolerated within the treatment group and shows evidence of being an effective treatment for alkaptonuria.
ACHONDROPLASIA		
C-Type Natriuretic Peptide Analogue Therapy in Children with Achondroplasia	N Engl J Med 2019; 378(1):25-35	**Title**: C-Type Natriuretic Peptide Analogue Therapy in Children with Achondroplasia **Purpose**: To assess the efficacy and safety of vosoritide at treating achondroplasia in children **Methods**: RCT consisting of 35 children aged 5 to 14 with achondroplasia. Dosages were stratified based on weight; dose of 2.5 µg per kilogram of body weight (8 patients in cohort 1), 7.5 µg per kilogram (8 patients in cohort 2), 15.0 µg per kilogram (10 patients in cohort 3), or 30.0 µg per kilogram (9 patients in cohort 4). Patients were observed for 24 mo. The outcomes of interest were prevalence of adverse events and growth velocity. **Results**: Each patient experienced minor adverse effects such as pyrexia, hypothermia, erythema, cough, swelling and headaches. 4/35 patients experienced severe adverse effects including grade 3 obstructive sleep apnea, grade 1 tonsillar hypertrophy, grade 3 thyroglossal cyst, and grade 3 syrinx. At 6 mo, there were increases in annualized growth velocity in all cohorts except for that which received 2.5 µg. **Conclusion**: Although associated with mild side effects, with larger scale trials, vosoritide may be used as a treatment for achondroplasia in children.

Acronyms

^{18}FDG	18-fluorodeoxyglucose
ADC	apparent diffusion coefficient
AP	anteroposterior
ARDS	acute respiratory distress syndrome
AV	arteriovenous
BOOP	bronchiolitis obliterans organizing pneumonia
CNS	central nervous system
CT	computed tomography
CTA	computed tomographic angiogram
CVD	collagen vascular disease
CVP	central venous pressure
DDH	developmental dysplasia of the hip
DEXA	dual-energy x-ray absorptiometry
DMSA	dimercaptosuccinic acid
DSA	digital subtraction angiography
DTPA	diethylene triamine pentaacetic acid
DWI	diffusion-weighted image
ECD	ethyl cysteinate dimer
eGFR	estimated glomerular filtration rate
ERCP	endoscopic retrograde cholangio-pancreatography
FLAIR	fluid-attenuated inversion recovery
FNA	fine needle aspiration
GPA	granulomatosis with polyangiitis
HCC	hepatocellular carcinoma
HIDA	hepatobiliary iminodiacetic acid
HMPAO	hexamethylpropyleneamine oxime
HSG	hysterosalpingogram
IBD	inflammatory bowel disease
ICS	intercostal space
ICV	ileocecal valve
IPF	interstitial pulmonary fibrosis
IVP	intravenous pyelogram
KUB	kidneys, ureters, bladder
LA	left atrium
LLL	left lower lobe
LLQ	left lower quadrant
LUL	left upper lobe
LUQ	left upper quadrant
LV	left ventricle
MAA	macroaggregated albumin
MAG3	mertiatide
MCA	middle cerebral artery
MIBG	metaiodobenzylguanidine
MR	magnetic resonance
MRA	magnetic resonance angiogram
MRCP	magnetic resonance cholangiopancreatography
MS	multiple sclerosis
MUGA	multiple gated acquisition
PA	posteroanterior
PBD	percutaneous biliary drainage
PET	positron emission tomography
PFT	pulmonary function test
PICC	peripherally-inserted central catheter
PTA	percutaneous transluminal angioplasty
PTC	percutaneous transhepatic cholangiography
RA	right atrium
RAIU	radioactive iodine uptake
RLL	right lower lobe
RLQ	right lower quadrant
RML	right middle lobe
RUL	right upper lobe
RUQ	right upper quadrant
RV	right ventricle
SPECT	single photon emission computed tomography
SVC	superior vena cava
TIA	transient ischemic attack
TNK	tenecteplase
tPA	tissue plasminogen activator
TPN	total parenteral nutrition
TRUS	transrectal ultrasound
TVUS	transvaginal ultrasound
UPJ	ureteropelvic junction
U/S	ultrasound
VCUG	voiding cystourethrogram
V/Q	ventilation/perfusion

Imaging Modalities

X-Ray Imaging

- x-rays: form of short wavelength electromagnetic energy
- as x-ray photons traverse matter, they can be absorbed (a process known as "attenuation") and/or scattered
- the density of a structure determines its ability to attenuate or "weaken" the x-ray beam
  - air < fat < water < bone < metal
- structures that have high attenuation (e.g. bone) appear white on the resulting images

Plain Films

- x-rays pass through the patient and interact with a detection device (film) to produce a 2-dimensional projection image
- structures closer to the film appear sharper and less magnified
- contraindications: pregnancy (relative)
- advantages: inexpensive, non-invasive, readily available, portable, reproducible, fast, easily read
- disadvantages: radiation exposure (minimal), generally poor at distinguishing soft tissues

Fluoroscopy

- continuous x-rays used for guiding angiographic and interventional procedures, in contrast examinations of the GI tract, and in the OR for certain surgical procedures (e.g. orthopedic, urological)
- on the fluoroscopic image, structures that are radiolucent on plain film appear bright, and structures that are radiopaque on plain film appear dark
- in comparison to continuous fluoroscopy, pulsed fluoroscopy reduces fluoroscopy time and radiation dose
- advantages: real-time visualization of structures
- disadvantages: increased radiation dose compared to plain films

Computed Tomography

- x-ray beam opposite a detector moves in a continuous 360° arc as patient is advanced through the scanner
  - anatomical structures are then reconstructed
- attenuation is quantified in Hounsfield units:
  - windowing and leveling: adjusting the "window width" (range of Hounsfield units displayed) and "window level" (midpoint value of the window width) to maximally visualize certain anatomical structures (e.g. CT chest can be viewed using "lung," "soft tissue," and "bone" settings)
- contraindications: pregnancy (relative), adverse reactions to contrast agents (e.g. previous anaphylaxis allergy, renal failure)
- advantages: delineates soft tissues, excellent at delineating bones and identifying lung/liver masses, may be used to guide biopsies, helical multidetector CT has fast data acquisition and allows 3D reconstruction, CTA is non-invasive compared to conventional angiography for visualization of vasculature
- disadvantages: high radiation exposure, soft tissue characterization is inferior to MRI, some studies require contrast (e.g. IV, oral, rectal), patient anxiety when going through scanner, increased cost and decreased availability compared to plain film, requires expert interpretation of images

Typical Effective Doses from Diagnostic Medical Exposures (in Adults)*

Diagnostic Procedure Type	Equivalent Number of Chest X-Rays	Approximate Equivalent Period of Natural Background Radiation** (~3 mSv/yr)
X-Ray		
Skull	5	12 d
Cervical spine	10	3 wk
Thoracic spine	50	4 mo
Lumbar spine	75	6 mo
Chest (single PA film)	1	2 d
Shoulder	0.5	1 d
Mammography	20	7 wk
Abdomen	35	3 mo
Hip	35	3 mo
Pelvis	30	10 wk
Knee	0.25	<1 d
IV urogram	150	1 yr
Dual-energy x-ray absorptiometry (without/with CT)	0.5/2	<1 d/4 d
Upper GI series	300	2 yr
Small bowel series	200	20 mo
Barium enema	400	2.7 yr
CT		
Head	100	8 mo
Neck	150	1 yr
Spine	300	2 yr
Chest	350	2.3 yr
Chest (pulmonary embolism)	750	5 yr
Coronary angiography	800	5.3 yr
Abdomen	400	2.7 yr
Pelvis	300	2 yr
Radionuclide		
Brain (^{18}FDG)	705	4.7 yr
Bone (^{99m}Tc)	315	2.1 yr
Thyroid (^{99m}Tc)	240	1.6 yr
Thyroid (^{123}I)	95	8 mo
Cardiac rest-stress test		
(^{99m}Tc 1-d)	470	3 yr
(^{99m}Tc 2-d)	640	4 yr
Lung ventilation (^{133}Xe)	25	2 mo
Lung perfusion (^{99m}Tc)	100	8 mo
Renal (^{99m}Tc)	90-165	7-13 mo
Liver-spleen (^{99m}Tc)	105	8.4 yr
Biliary tract (^{99m}Tc)	155	1 yr

**Calculated using average natural background exposure in Canada

Canada.ca: Occupational radiation exposure [Internet]. Government of Canada; [updated 2023 June 2; cited 2023 July 4]. Available from: http://www.hc-sc.gc.ca/hl-vs/iyh-vsv/environ/expos-eng.php

Ultrasound

- high-frequency sound waves are transmitted from a transducer and passed through tissues; reflections of the sound waves are picked up by the transducer and transformed into images
- reflection (or "echo") occurs when the sound waves reflect off tissue interfaces of different acoustic impedance
- structures are described based on their echogenicity:
  - hyperechoic (echogenic) structures appear bright (U/S reflected) whereas hypoechoic structures appear dark (U/S waves are relatively less reflected with more waves passing through the structure)
  - a simple cyst is anechoic (pure black) as there are no interfaces to produce any echoes
- a gel is used on the skin surface to reduce the difference of impedance between the skin and transducer
- use of higher frequencies on U/S results in greater resolution but poorer penetrance, thus decreased visualization of deeper structures
- artifacts: acoustic shadowing refers to the echo-free area located behind an interface that strongly reflects (e.g. air) or absorbs (e.g. bone) sound waves; enhancement refers to the increase in reflection amplitude (i.e. increased brightness) from objects that lie below a weakly attenuating structure (e.g. cyst)
- duplex scan: grey-scale imaging that utilizes the Doppler effect (sound reflecting off a moving target) to visualize the velocity of blood moving past the transducer
- colour Doppler: assigns a colour based on the direction of blood flow (i.e. red = toward transducer, blue = away)
- advantages: relatively low cost, excellent spatial and soft tissue contrast resolution, non-invasive, no radiation, portable, real-time imaging, may be used for guided biopsies, many different imaging planes (axial, sagittal), differentiates cystic vs. solid
- disadvantages: highly operator-dependent, air in bowel may prevent imaging of midline structures in the abdomen, may be limited by patient habitus, poor for bone evaluation, limited field-of-view

Attenuation
Bone (= bright) > grey matter > white matter ("fatty" myelin) > CSF > air (= dark)

Magnetic Resonance Imaging

- imaging technique that uses electromagnetic properties of tissue (mainly water) to produce images in virtually any plane. It does not use ionizing radiation
- patient is placed in a magnetic field generated by electric current; protons, typically from water molecules, align themselves along the direction of magnetization due to their intrinsic polarity; a pulsed radiofrequency beam is subsequently turned on and deflects all the protons off their aligned axes; when the radiofrequency beam is turned off, the protons return to their pre-excitation axis, giving off the energy they absorbed; this energy is measured with a detector and interpreted by software to generate MR images
- MR image reflects signal intensity picked up by receiver. Signal intensity is dependent on:
  1. hydrogen density: tissues with low hydrogen density (e.g. cortical bone, lung) generate little to no MR signal compared to tissues with high hydrogen density (e.g. water)
  2. magnetic relaxation times (T1 and T2): reflect quantitative alterations in MR signal strength due to intrinsic properties of the tissue and its surrounding chemical and physical environment

Remember that water is "**w**hite" on **T2** as "**W**orld **W**ar **II**"

Methods to Reduce the Risk of Contrast-Induced Nephropathy
- Optimal: 0.9% NaCl at 1 mL/kg/h for 12 h pre-procedure and 12 h post-contrast administration
- For same-day procedure: 0.9% NaCl or $NaHCO_3$ at 3 ml/kg/h for 1-3 h pre-procedure and for 6 h post-contrast administration

Table 1. Differences Between Diffusion, T1- and T2-Weighted MR Imaging

Imaging Techniques	Signal Intensity	Main Application	Advantages
Diffusion-Weighted Imaging	Signal intensity dependent on the free molecular motion of water Decreased diffusion is hyperintense (bright), whereas increased diffusion is hypointense (dark)	Neuroradiology	Sensitive for detection of acute ischemic stroke and differentiating an acute stroke from other neurologic pathologies Acute infarction and abscess collections appear hyperintense due to restricted diffusion
T1-Weighted	Fluid is hypointense (dark) and fat is hyperintense (bright)	Body soft tissues	Often considered an anatomic scan since it provides a reference for functional imaging
T2-Weighted	Fluid is hyperintense (bright) and fat is hypointense (dark)	Body soft tissues	Often considered a pathologic scan since it will highlight edematous areas associated with certain pathologies

Positron Emission Tomography Scans

- nuclear tracers are employed to produce images of functional processes in the body
- current generation models integrate PET and CT technologies into a single imaging device (PET-CT) that collects both anatomic and functional information during a single acquisition
- positron-producing radioisotopes, such as 18F, are chemically incorporated into a metabolically active molecule (e.g. glucose); these are then injected into the patient, where they travel to and accumulate in the tissues of interest; as the radioactive substance decays, γ rays are produced, and are detected by the PET scanner

Contraindications to IV Contrast

MADD Failure
Multiple myeloma
Adverse reaction previously
DM
Dehydration
Failure (renal, severe heart)

- contraindications: pregnancy
- advantages: shows metabolism and physiology of tissues (not only anatomic); in oncology, allows for diagnosis, staging, and restaging; has predictive and prognostic value; can evaluate cardiac viability
- disadvantages: cost, ionizing radiation, availability

Contrast Agents

Table 2. Contrast Agents

Imaging Modality	Types	Advantages	Disadvantages	Contraindications
X-Ray	Barium (e.g. oral or rectal)	Radiopaque substance that helps to delineate intraluminal anatomy; may demonstrate patency, lumen integrity, or large filling defects		Previous adverse reaction to contrast; barium enema is contraindicated in toxic megacolon, acute colitis, and suspected perforation
CT	Iodinated agents (routes = oral, rectal, IV)	Delineates intraluminal anatomy; may demonstrate patency, lumen integrity, or large filling defects; under fluoroscopy, may also give information on function of an organ		Previous adverse reaction to contrast, renal failure, DM, pregnancy, multiple myeloma, severe heart failure, and dehydration eGFR <60 may require preventative measures and follow-up
MRI	Gadolinium Chelates	Shortens T1 relaxation time, thereby increasing signal intensity in T1-weighted sequences; highlights highly vascular structures (e.g. tumours)	Risk of nephrogenic systemic fibrosis in patients with end-stage renal disease	Previous adverse reaction to contrast or end-stage renal disease (relative contraindication)
U/S	Microbubbles (IV)	Tiny gas bubbles create many interfaces and appear very echogenic. The microbubbles allow for echo-enhancement of vascular structures or cavities (i.e. echocardiography)		Contraindicated in individuals with right-to-left cardiac shunts or people with known hypersensitivity reactions

FDG PET Imaging in Patients with Pathologically Verified Dementia
J Nucl Med 2000;41(11):1920-28
Purpose: To confirm two beliefs surrounding bilateral temporo-parietal hypometabolism on FDG PET in Alzheimer's disease (AD): (1) it is the metabolic abnormality associated with AD and (2) that sensitivity, specificity, and diagnostic accuracy of this metabolic pattern allows for AD to be differentiated from other degenerative causes of dementia.
Methods: FDG PET scans from 22 individuals with pathologic confirmation of AD diagnosis were visually graded by an experienced nuclear medicine physician to identify classic bilateral temporo-parietal hypometabolism.
Results: Sensitivity, specificity, and diagnostic accuracy of bilateral temporo-parietal hypometabolism for AD were 93%, 63%, and 82%, respectively.
Conclusions: Bilateral temporo-parietal hypometabolism is the classic metabolic abnormality associated with AD. FDG PET may identify this metabolic pattern and can be used clinically to differentiate dementia syndromes.

Chest Imaging

Chest X-Ray

Standard Views

- PA: anterior chest against film plate to minimize magnification of the cardiac silhouette
- lateral: better visualization of retrocardiac space and thoracic spine; more sensitive at detecting small pleural effusions
  - improves localization of lesions when combined with PA view
- AP: alternative to PA view for admitted or acutely ill patients who are unable to tolerate standing or transport; erect or supine; generally a lower quality film than PA because of magnified cardiac silhouette
- lateral decubitus: can help to assess for pleural effusion and pneumothorax; however, POCUS can also be utilized for both of these purposes
- lordotic: angled beam allowing better visualization of apices normally obscured by the clavicles and anterior ribs on PA and AP views

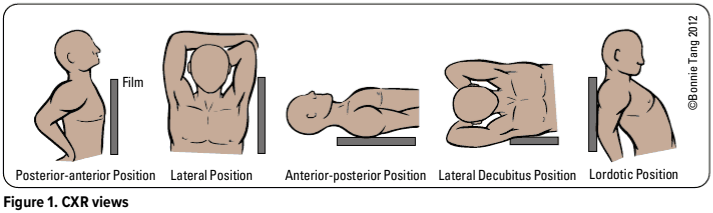

Figure 1. CXR views

Approach to CXR

Basics

- ID: patient name, medical record number (MRN), sex, age
- date of exam
- markers: right and/or left
- technique: view (e.g. PA, AP, lateral), supine or erect
- indications for the study
- comparison: date of previous study for comparison (if available)
- quality of film: inspiration (10 posterior and 7 anterior ribs should be visible), penetration (thoracic spine should be visible), rotation (spinous processes should be equidistant from medial ends of clavicles), magnification (AP films magnify the heart), angulation (clavicles should be S shaped)

Analysis

- tubes and lines: check position and be alert for pneumothorax or pneumomediastinum
- soft tissues: neck, axillae, pectoral muscles, breasts/nipples, chest wall
  - nipple markers can help identify nipples (may mimic lung nodules)
  - amount of soft tissue (check for any asymmetry), presence of masses, presence of air (subcutaneous emphysema)
- abdomen (see *Abdominal Imaging, MI11*)
  - free air under the diaphragm, air-fluid levels, distention in small and large bowel
  - herniation of abdominal contents (i.e. diaphragmatic hernia)
- bones: cervical spine, thoracic spine, scapulae, ribs, sternum, clavicles, proximal humerus
  - lytic and sclerotic lesions, fractures
- mediastinum: trachea, heart, great vessels
  - cardiomegaly (cardiothoracic ratio >0.5 on PA), tracheal shift, tortuous aorta, widened mediastinum
- hila: pulmonary vessels, mainstem and segmental bronchi, lymph nodes
- lungs: parenchyma, interstitium, pleura, diaphragm
  - abnormal lung opacity, pleural effusions, or thickening
  - right hemidiaphragm usually higher than left due to liver
  - right vs. left hemidiaphragm can be discerned on lateral CXR due to heart resting directly on left hemidiaphragm
- please refer to Toronto Notes website for supplementary material on how to approach a CXR

st	sternum
svc	superior vena cava
tr	trachea
vb	vertebral body

Figure 2. Location of fissures, mediastinal structures, and bony landmarks on CXR
Note that anterior space is also commonly called retrosternal space

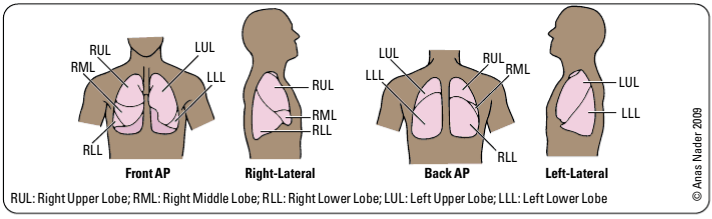

Figure 3. Location of lobes of the lung

Localizing Lesions for Parenchymal Lung Disease

- silhouette sign: when two objects of the same radiodensity abut, they appear indistinguishable on imaging (i.e. the silhouette expected at an anatomical border due to difference in density disappears)
  - can be used to identify lung pathology (consolidation, atelectasis, mass) and localize disease to specific lung segments
- spine sign: on lateral films, vertebral bodies should appear progressively radiolucent (dark) as one moves down the thoracic vertebral column; if they appear more radiopaque, it is an indication of pathology (e.g. consolidation in overlying lower lobe)
- air bronchogram: branching pattern of air-filled bronchi made visible on a background of opacification (i.e. solid or fluid-filled alveoli)

Table 3. Localization Using the Silhouette Sign

Interface Lost	Location of Lung Pathology
SVC/right superior mediastinum	RUL
Right heart border	RML
Right hemidiaphragm	RLL
Aortic knob/left superior mediastinum	LUL
Left heart border	Lingula
Left hemidiaphragm	LLL

Chest Computed Tomography

Approach to CT Chest

- soft tissue window
  - thyroid, chest wall, pleura
  - heart: chambers, coronary artery calcifications, pericardium
  - vessels: aorta, pulmonary artery, smaller vasculature
  - lymph nodes: mediastinal, axillary, hilar
- bone window
  - vertebrae, sternum, ribs: fractures, lytic lesions, sclerosis
- lung window
  - trachea: patency, secretions
  - bronchi: anatomic variants, mucus plugs, airway collapse
  - lung parenchyma: nodules, fibrosis, interstitial changes, consolidation, atelectasis
  - pleural space: effusions, thickening

Table 4. Types of CT Chest

	Advantage	Disadvantage	Contrast	Indication
Standard	Scans full lung very quickly (<1 min) ± high resolution reconstructions	Radiation	±	CXR abnormality Pleural and mediastinal abnormality Lung cancer staging Cancer follow-up Empyema vs. abscess
Low Dose	1/5th the radiation	Decreased detail	No	Lung cancer screening Follow-up infections, lung transplant, metastases
CTA	Iodinated contrast highlights vasculature (scan timed for maximum opacification of vessel being studied)	Contrast can cause severe allergic reaction and can cause acute kidney injury	Yes	PE Aortic aneurysms Aortic dissection

Figure 4. CT thorax windows in axial view

Lung Abnormalities

Atelectasis

- pathogenesis: collapse of lung tissue due to restricted breathing, blockage of bronchi, external compression, or poor surfactant
- findings
  - increased opacity of involved segment/lobe, vascular crowding, silhouette sign, air bronchograms
  - volume loss: fissure displacement, hilar/mediastinal displacement, diaphragm elevation
  - compensatory hyperinflation of remaining normal lung
- differential diagnosis
  - obstructive (most common): alveolar air distal to obstruction is resorbed causing alveolar collapse
    - postsurgical, endobronchial lesion, foreign body, inflammation (granulomatous infections, pneumoconiosis, sarcoidosis, radiation injury), or mucous plug (cystic fibrosis)
  - compressive: tumour, bulla, effusion, enlarged heart, lymphadenopathy
  - traction (cicatrization): due to scarring, which distorts alveoli and contracts the lung
  - adhesive: due to lack of surfactant
    - hyaline membrane disease, prematurity
  - passive (relaxation): a result of air or fluid in the pleural space preventing full aeration
    - pleural effusion, pneumothorax
- management: in the absence of a known etiology, persisting atelectasis must be investigated (i.e. CT thorax or bronchoscopy) to rule out bronchogenic carcinoma centrally

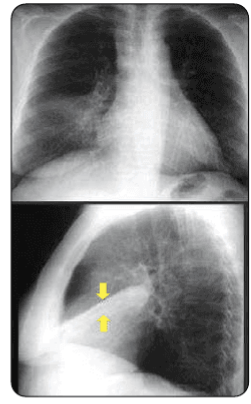

Figure 5. Atelectasis: RML collapse

Consolidation

- pathogenesis: air in alveoli replaced by fluid (transudate, blood), inflammatory exudates, protein, or tumour
- findings
  - air bronchograms: lucent branching bronchi visible through opacification
  - airspace nodules: fluffy, patchy, poorly defined margins with later tendency to coalesce, may take on lobar or segmental distribution
  - silhouette sign
- differential diagnosis
  - fluid: transudate (pulmonary edema), blood (trauma, vasculitis, bleeding disorder, pulmonary infarct)
  - inflammatory exudates: bacterial infections, TB, allergic hypersensitivity alveolitis, COP (cryptogenic organizing pneumonia), allergic bronchopulmonary aspergillosis, aspiration, sarcoidosis
  - protein: pulmonary alveolar proteinosis
  - tumour: adenocarcinoma, lymphoma
- management: varies depending on the pattern of consolidation, which can suggest different etiologies; should also be done in the context of clinical picture

DDx of Airspace Disease

- Pus (e.g. infections such as pneumonia)
- Fluid (e.g. pulmonary edema)
- Blood (e.g. pulmonary hemorrhage)
- Cells (e.g. bronchioalveolar carcinoma, lymphoma)
- Protein (e.g. alveolar proteinosis)

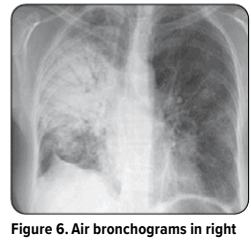

Figure 6. Air bronchograms in right lung

Interstitial Disease

- pathogenesis: pathological process involving pulmonary interstitium (i.e. "lung scaffolding")
- findings
  - septal thickening: fine lines caused by thickened connective tissue septae (most commonly due to pulmonary edema or lymphangitis carcinomatosis)
    - these manifest on CXR as:
      - Kerley A: long thin lines in upper lobes
      - Kerley B: short horizontal lines extending from lateral lung margin
      - Kerley C: diffuse linear pattern throughout lung
  - nodular pattern: 1-5 mm well-defined or ill-defined nodules distributed throughout lung or with a lung zone predominance
    - seen in metastases, pneumoconiosis, granulomatous disease (e.g. sarcoidosis, miliary TB)
  - reticular pattern: fine curvilinear opacities
    - seen in interstitial lung diseases (pulmonary fibrosis)
    - watch for pneumothorax as a complication
  - reticulonodular: combination of reticular and nodular patterns
  - may also see signs of airspace disease (atelectasis, consolidation)
- differential diagnosis
  - occupational/environmental exposure
    - inorganic: asbestosis, coal miner's pneumoconiosis, silicosis, berylliosis, talc pneumoconiosis
    - organic: hypersensitivity pneumonitis, bird fancier's lung, farmer's lung (mouldy hay), and other organic dust
  - autoimmune: connective tissue diseases (e.g. rheumatoid arthritis, scleroderma, SLE, polymyositis, mixed connective tissue disease), IBD, celiac disease, vasculitis
  - drug-related: antibiotics (cephalosporins, nitrofurantoin), NSAIDs, phenytoin, carbamazepine, fluoxetine, amiodarone, chemotherapy (e.g. methotrexate), immunotherapy, heroin, cocaine, methadone

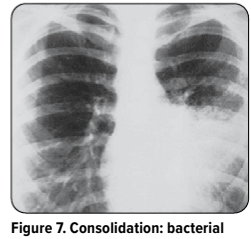

Figure 7. Consolidation: bacterial pneumonia

- infections: TB, non-tuberculous mycobacteria, certain fungal infections, viral infections
- idiopathic: IPF, nonspecific interstitial pneumonia (NSIP), organizing pneumonia
- for causes of interstitial lung disease classified by distribution, see Respirology, R13

• management: high-resolution CT thorax and ± open lung biopsy, multidisciplinary team discussions

Pulmonary Nodule

• findings
- round opacity <3 cm (>3 cm is considered a mass) ± silhouette sign
- note: do not mistake nipple shadows for nodules; if in doubt, repeat CXR with nipple markers

• differential diagnosis
- extrapulmonary density: nipple, skin lesion, electrode, pleural mass, bony lesion
- solitary nodule
  - tumour: carcinoma, hamartoma, metastasis, bronchial adenoma
  - infection/inflammation: histoplasmoma, tuberculoma, coccidioidomycosis
  - vascular: AV fistula, pulmonary varix (dilated pulmonary vein), infarct, septic embolus
- multiple nodules: metastases, abscess, granulomatous lung disease (TB, fungal, sarcoid, rheumatoid nodules, silicosis, GPA), septic emboli

• management: clinical information and CT appearance determine level of suspicion of malignancy
- if high probability of malignancy, invasive testing (transbronchial or CT-guided transthoracic biopsy) ± PET/CT is indicated
- if low probability of malignancy, follow-up imaging as per Fleischner guidelines 2017

Table 5. Characteristics of Benign and Malignant Pulmonary Nodules

	Malignant	Benign
Margin	Ill-defined/spiculated ("corona radiata")	Well-defined
Contour	Lobulated	Smooth
Calcification	Eccentric or stippled	Diffuse, central, popcorn, concentric
Doubling Time	20-460 d	<20 d or >460 d
Other Features	Cavitation, collapse, adenopathy, pleural effusion, lytic bone lesions, smoking history	
Size	>3 cm	<3 cm
Cavitation	Yes, especially with wall thickness >15 mm, eccentric cavity, and shaggy internal margins	No
Satellite Lesions	No	Yes

Pulmonary Vascular Abnormalities

Pulmonary Edema

• pathogenesis: fluid accumulation in the airspaces of the lungs

• findings
- vascular redistribution/enlargement, cephalization, pleural effusion, cardiomegaly (may be present in cardiogenic edema and fluid overloaded states)
- fluid initially collects in interstitium
- loss of definition of pulmonary vasculature
- peribronchial cuffing
- Kerley B lines
- reticulonodular pattern

• thickening of interlobar fissures
- as pulmonary edema progresses, fluid collects in alveoli and causes diffuse airspace disease, often in a "bat wing" or "butterfly" pattern in perihilar regions (outermost lung fields tend to be spared)

• differential diagnosis: cardiogenic (e.g. CHF), renal failure, volume overload, non-cardiogenic (e.g. ARDS)

Pulmonary Embolism

• pathogenesis: blockage in the pulmonary arteries due to emboli from pelvic or leg veins, rarely from central venous catheters, air, fat, or amniotic fluid

• findings
- generally not possible to definitively diagnose on plain film; diagnosis made by CT pulmonary angiography or ventilation/perfusion scintigraphy (VQ scan)
- CXR: Westermark sign (localized pulmonary oligemia), Hampton's hump (triangular peripheral infarct), enlarged right ventricle and right atrium, atelectasis, pleural effusion, and rarely pulmonary edema
- definitive imaging study: CT pulmonary angiography to look for filling defect in contrast-filled pulmonary arteries
- VQ scan: can be used in patients with impaired renal function or in pregnancy

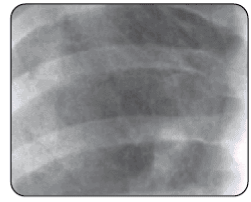

Figure 8. Interstitial disease: fine reticular pattern

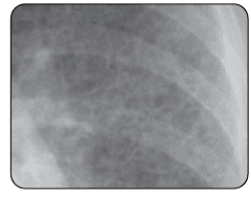

Figure 9. Interstitial disease: medium reticular pattern

DDx of Interstitial Lung Disease

FASSTEN (upper lung disease)
Farmer's lung (hypersensitivity pneumonitis)
Ankylosing spondylitis
Sarcoidosis
Silicosis
TB
Eosinophilic granuloma (Langerhans cell histiocytosis)
Neurofibromatosis

BAD RASH (lower lung disease)
Bronchiolitis obliterans organizing pneumonia (BOOP)
Asbestos
Drugs (nitrofurantoin, hydralazine, isoniazid, amiodarone, many chemotherapy drugs)
Rheumatological disease
Aspiration
Scleroderma
Hamman Rich and idiopathic pulmonary fibrosis (IPF)

DDx for Cavitating Lung Nodule

WEIRD HOLES
Wegener's (GPA)
Embolic (pulmonary, septic)
Infection (anaerobes, pneumocystis, TB)
Rheumatoid (necrobiotic nodules)
Developmental cysts (sequestration)
Histiocytosis
Oncological
Lymphangioleiomyomatosis
Environmental, occupational
Sarcoidosis

Pleural Abnormalities

Pleural Effusion

Table 6. Sensitivity of Plain Film Views for Pleural Effusion

X-Ray Projection	Minimum Volume to Visualize
Lateral decubitus	25 mL: most sensitive
Upright lateral	50 mL: meniscus seen in the posterior costophrenic sulcus
PA	200 mL
Supine	Variable (May appear as diffuse haziness)

- a horizontal fluid level is seen only in a hydropneumothorax (i.e. both fluid and air within pleural cavity)
- effusion may exert mass effect, shift trachea and mediastinum to opposite side, or cause atelectasis of adjacent lung
- U/S is superior to plain film for detection of small effusions and may also aid in thoracentesis; POCUS is now standard of care in acute situations

Pneumothorax

- pathogenesis: gas/air accumulation within the pleural space resulting in separation of the lung from the chest wall
- findings
  - upright chest film allows visualization of visceral pleura as curvilinear line paralleling chest wall, separating partially collapsed lung from pleural air
  - more obvious on expiratory (increased contrast between lung and air) or lateral decubitus films (air collects superiorly)
  - more difficult to detect on supine film; look for the "deep (costophrenic) sulcus" sign, "double diaphragm" sign (dome and anterior portions of diaphragm outlined by lung and pleural air, respectively), hyperlucent hemithorax, sharpening of adjacent mediastinal structures
  - contralateral tracheal and mediastinal shift may occur in tension pneumothorax
- differential diagnosis: spontaneous (tall and thin males, smokers), iatrogenic (lung biopsy, ventilation, central venous catheter insertion, thoracentesis), trauma (associated with rib fractures), emphysema, malignancy, honeycomb lung
- management: supplemental oxygen and observation, chest tube insertion in 5th ICS anterior axillary line, or emergent needle decompression in 2nd ICS midclavicular line if tension pneumothorax (followed by chest tube insertion); repeat CXR to ensure resolution

Asbestos

- asbestos exposure may cause various pleural abnormalities including benign plaques (most common; these may calcify), diffuse pleural fibrosis, effusion, and malignant mesothelioma

Mediastinal Abnormalities

Mediastinal Mass

- Felson's method of division outlines three compartments, which provides an approach to the differential diagnosis of a mediastinal mass
- anterior compartment is bordered anteriorly by the sternum and posteriorly by the heart and great vessels
  - 4 Ts: thyroid, thymic neoplasm, teratoma, terrible lymphoma
  - cardiophrenic angle mass differential: thymic cyst, epicardial fat pad, foramen of Morgagni hernia
- middle compartment extends from the posterior border of anterior mediastinum to a line 1 cm posterior to the anterior edge of thoracic vertebral bodies
  - esophageal carcinoma, esophageal duplication cyst, metastatic disease, lymphadenopathy (all causes), hiatus hernia, bronchogenic cyst
- posterior border (posterior to the middle line described above)
  - neurogenic tumour (e.g. neurofibroma, schwannoma), neurenteric cyst, thoracic duct cyst, lateral meningocele, Bochdalek hernia, extramedullary hematopoiesis
- any compartment may give rise to lymphoma, lung cancer, aortic aneurysm or other vascular abnormalities, abscess, or hematoma

Enlarged Cardiac Silhouette

- heart borders
  - on PA view, right heart border is formed by right atrium; left heart border is formed by left atrium and left ventricle
  - on lateral view, anterior heart border is formed by right ventricle; posterior border is formed by left atrium (superior to left ventricle) and left ventricle

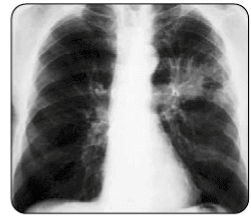

Figure 10. LUL mass: bronchogenic carcinoma

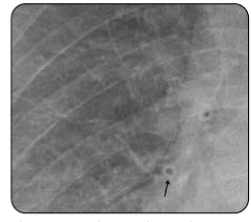

Figure 11. Peribronchial cuffing: interstitial edema

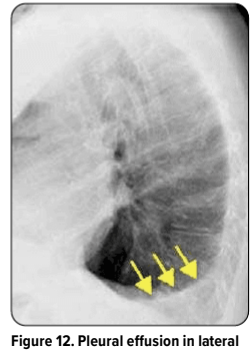

Figure 12. Pleural effusion in lateral view

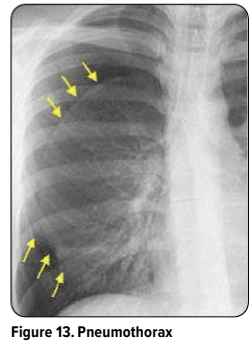

Figure 13. Pneumothorax

- cardiothoracic ratio = greatest transverse dimension of the central shadow relative to the greatest transverse dimension of the thoracic cavity
  - using a good quality erect PA chest film in adults, cardiothoracic ratio of >0.5 is abnormal
  - differential of ratio >0.5
    - cardiomegaly (myocardial dilatation or hypertrophy)
    - pericardial effusion
    - poor inspiratory effort/low lung volumes
    - pectus excavatum
  - ratio <0.5 does not exclude enlargement
- pericardial effusion: globular heart with loss of indentations on left mediastinal border
- RA enlargement: increase in curvature of right heart border and enlargement of SVC
- LA enlargement: straightening of left heart border; increased opacity of lower right side of cardiovascular shadow (double heart border); elevation of left main bronchus (specifically, the upper lobe bronchus on the lateral film); distance between left main bronchus and "double" heart border >7 cm; splayed carina (late sign)
- RV enlargement: elevation of cardiac apex from diaphragm; anterior enlargement leading to loss of retrosternal air space on lateral; increased contact of right ventricle against sternum
- LV enlargement: rounding of the cardiac apex; displacement of left cardiac border leftward, inferiorly, and posteriorly

Elevated Hemidiaphragm Suggests
PAL DIP
Pregnancy
Atelectasis
Lung resection
Diaphragmatic paralysis
Intra-abdominal process
Pneumonectomy
Pleural effusion also may result in apparent elevation

Depressed Hemidiaphragm Suggests
TALC
Tumour
Asthma
Large pleural effusion
COPD

Tubes, Lines, and Catheters

- ensure appropriate placement and assess potential complications of lines and tubes
- avoid mistaking a line/tube for pathology (e.g. oxygen rebreather mask for pneumothoraces)

Central Venous Catheter
- used for fluid and medication administration, vascular access for hemodialysis, and CVP monitoring
- ideally located at the SVC/atrial junction to prevent inducing arrhythmias or perforating wall of atrium
  - if monitoring CVP, catheter tip must be proximal to venous valves
- tip of well-positioned central venous catheter projects over silhouette of SVC in a zone demarcated superiorly by the anterior first rib end and clavicle, and inferiorly by top of RA
- course should parallel that of the SVC; if appears to bend as it approaches wall of SVC or appears perpendicular, catheter may damage and ultimately perforate wall of SVC
- complications: pneumothorax, bleeding (mediastinal, pleural), malposition (artery, pleura), air embolism

Endotracheal Tube
- frontal chest film: tube projects over trachea and shallow oblique or lateral chest radiograph will help determine position in 3 dimensions
- progressive gaseous distention of stomach on repeat imaging is concerning for esophageal intubation
- tip should be located 2-4 cm above tracheal carina (avoids bronchus intubation and vocal cord irritation)
- maximum inflation diameter <3 cm to avoid necrosis of tracheal mucosa and rupture; ensure diameter of balloon is less than tracheal diameter above and below balloon
- complications: aspiration (parenchymal opacities), pharyngeal perforation (subcutaneous emphysema, pneumomediastinum, mediastinitis)

Nasogastric Tube
- tip and side port should be positioned distal to esophagogastric junction and proximal to gastric pylorus
- radiographic confirmation of tube is mandatory because clinical techniques for assessing tip position may be unreliable
- complications: aspiration (parenchymal opacities), pneumothorax

Swan-Ganz Catheter
- to monitor pulmonary capillary wedge pressure and estimate diastolic filling of left heart
- tip should be positioned within right or left main pulmonary arteries or in one of their large, lobar branches
- if tip is located more distally, increased risk of prolonged pulmonary artery occlusion resulting in pulmonary infarction or, rarely, pulmonary artery rupture/pseudoaneurysm
- complications: pneumothorax, bleeding (mediastinal, pleural), air embolism

Chest Tube
- in dorsal and caudal portion of pleural space to evacuate fluid
- in ventral and cephalad portions of pleural space to evacuate pneumothoraces
- tube may lie in fissure as long as functioning
- complications: bleeding, infection, lung laceration

DDx Anterior Mediastinal Mass
4 Ts
Thyroid
Thymic neoplasm
Teratoma
Terrible lymphoma

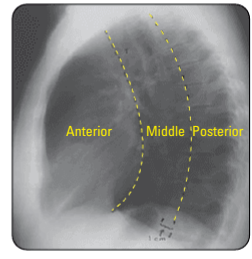

Figure 14. Lateral CXR showing three mediastinal compartments

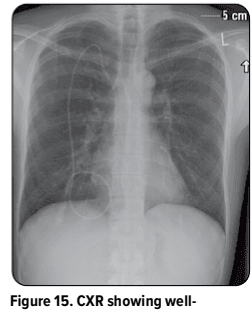

Figure 15. CXR showing well-positioned central venous catheter

Abdominal Imaging

Abdominal X-Ray

3 Views of AXR
Erect/Upright
Supine
Left lateral decubitus

Indications
- acute abdomen: bowel perforation, toxic megacolon, bowel ischemia, small bowel obstruction, large bowel obstruction
- chronic symptoms: constipation, calcifications (gallstones, renal stones, urinary bladder stones, etc.)
- not useful in: GI bleeds, chronic anemia, vague GI symptoms

Anatomy
- the abdomen is divided into 2 cavities:
  - peritoneal cavity: lined by peritoneum that wraps around most of the bowel, the spleen, and most of the liver; forms a recess lateral to both the ascending and descending colon (paracolic gutters)
  - retroperitoneal cavity: contains several organs situated posterior to the peritoneal cavity; the contour of these can often be seen on radiographs

Table 7. Differentiating Small and Large Bowel

Property	Small Bowel	Large Bowel
Mucosal Folds	Uninterrupted valvulae conniventes (or plicae circulares)	Interrupted haustra extend only partway across lumen
Location	Central	Peripheral (picture frame)
Maximum Diameter	3 cm	6 cm (9 cm at cecum)
Maximum Fold Thickness	3 mm	5 mm
Other	Rarely contains solid fecal material	Commonly contains solid fecal material

3-6-9 Rule of Dilation
Small bowel (>3 cm)
Large bowel (>6 cm)
Cecum (>9 cm)

Approach to Abdominal X-Ray
- mnemonic: "Free ABDO"
- "Free": free air and fluid
  - free fluid
    - small amounts of fluid: increased distance between lateral fat stripes and adjacent colon may indicate free peritoneal fluid in the paracolic gutters
    - large amounts of fluid: diffuse increased opacification on supine film; bowel floats to centre of anterior abdominal wall
    - ascites and blood (hemoperitoneum) are the same density on the radiograph and cannot be differentiated
  - free intraperitoneal air suggests rupture of a hollow viscus (anterior duodenum, transverse colon, etc.), penetrating trauma, or recent (<7 d) surgery
- "A": air in the bowel (can be normal, ileus, or obstruction)
  - volvulus – twisting of the bowel upon itself resulting in obstruction; from most to least common:
    1. sigmoid: massively dilated sigmoid projects to right or mid-upper abdomen with proximal dilation ("coffee bean" sign)
    2. cecal: massively dilated bowel loop projecting to left or mid-upper abdomen with small bowel dilation
    3. gastric: rare
    4. transverse colon: rare (usually in younger individuals)
    5. small bowel: "corkscrew" sign (rarely diagnosed on plain films, seen best on CT)
  - toxic megacolon
    - manifestation of fulminant colitis
    - extreme dilatation of colon (>6.5 cm) with mucosal changes (e.g. foci of edema, ulceration, pseudopolyps) and loss of normal haustral pattern
- "B": bowel wall thickening
  - increased soft tissue density in bowel wall, thumb-like indentations in bowel wall ("thumb-printing"), or a picket-fence appearance of the valvulae conniventes ("stacked coin" appearance)
  - may be seen in IBD, infection, ischemia, hypoproteinemic states, and submucosal hemorrhage
- "D": densities
  - bones: look for gross abnormalities of lower ribs, vertebral column, and bony pelvis
  - abnormal calcifications: approach by location
    - RUQ: renal stone, adrenal calcification, gallstone, porcelain gallbladder
    - RLQ: ureteral stone, appendicolith, gallstone ileus
    - LUQ: renal stone, adrenal calcification, tail of pancreas
    - LLQ: ureteral stone
    - central: aorta/aortic aneurysm, pancreas, lymph nodes
    - pelvis: phleboliths (i.e. calcified veins), uterine fibroids, bladder stones
- "O": organs
  - kidney, liver, gallbladder, spleen, pancreas, urinary bladder, psoas shadow
  - outlines can occasionally be identified because they are surrounded by more lucent fat, but all are best visualized with other imaging modalities (CT, MRI)

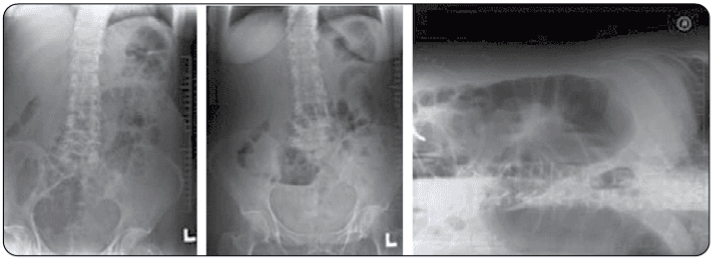

Figure 16. Normal AXRs: (left) supine anteroposterior AXR, (middle) upright anteroposterior AXR, and (right) left lateral decubitus AXR

Table 8. Abnormal Air on Abdominal X-Ray

Air	Appearance	Common Etiologies
Extraluminal Intraperitoneal (pneumoperitoneum)	Upright film: air under diaphragm Left lateral decubitus film: air between liver and abdominal wall Supine film: gas outlines of structures not normally seen: Inner and outer bowel wall ("Rigler's" sign) Falciform ligament Peritoneal cavity ("football" sign)	Perforated viscus Postoperative (up to 10 d to be resorbed)
Retroperitoneal	Gas outlining retroperitoneal structures allowing increased visualization: Psoas shadows Renal shadows	Perforation of retroperitoneal segments of bowel: duodenal ulcer, post-colonoscopy
Intramural (pneumatosis intestinalis)	Lucent air streaks in bowel wall, 2 types: 1. Linear 2. Rounded (cystoides type)	1. Linear: ischemia, necrotizing enterocolitis 2. Rounded/cystoides (generally benign): primary (idiopathic), secondary (COPD)
Intraluminal	Dilated loops of bowel, air-fluid levels	Adynamic (paralytic) ileus, mechanical bowel obstruction
Loculated	Mottled, localized in abnormal position without normal bowel features	Abscess
Biliary	Air centrally over liver	Sphincterotomy, gallstone ileus, erosive peptic ulcer, cholangitis, emphysematous cholecystitis
Portal Venous	Air peripherally over liver in branching pattern	Bowel ischemia/infarction

Table 9. Adynamic Ileus vs. Mechanical Obstruction

Feature	Adynamic Ileus	Mechanical Obstruction
Calibre of Bowel Loops	Normal or dilated	Usually dilated
Air-Fluid Levels (erect and left lateral decubitus films only)	Same level in the same single loop	Multiple air fluid levels giving "step ladder" appearance, dynamic (indicating peristalsis present), "string of pearls" (row of small gas accumulations in the dilated valvulae conniventes)
Distribution of Bowel Gas	Air throughout GI tract is generalized or localized In a localized ileus (e.g. pancreatitis, appendicitis), dilated "sentinel loop" remains in the same location on serial films, usually adjacent to the area of inflammation	Dilated bowel up to the point of obstruction (i.e. transition point) No air distal to obstructed segment "Hairpin" (180°) turns in bowel

Abdominal Computed Tomography

- indications for plain CT: renal colic, hemorrhage
- indications for CT with contrast:
  - IV contrast given immediately before or during CT to allow identification of arteries and veins
    - portal venous phase: indicated for majority of cases
    - biphasic (arterial and portal venous phases): liver, pancreas, bile duct tumours
    - caution: contrast allergy (may pre-medicate with steroids and antihistamine)
    - contraindication: impaired renal function (eGFR <30 mL/min/1.73 m ^{2})
  - oral contrast: barium or water-soluble (water soluble if suspected perforation) given in most cases to demarcate GI tract
  - rectal contrast: given for investigation of colonic lesions

Biliary vs. Portal Venous Air
"Go with the flow": air follows the flow of bile or portal venous blood
Biliary air is most prominent centrally over the liver
Portal venous air is most prominent peripherally

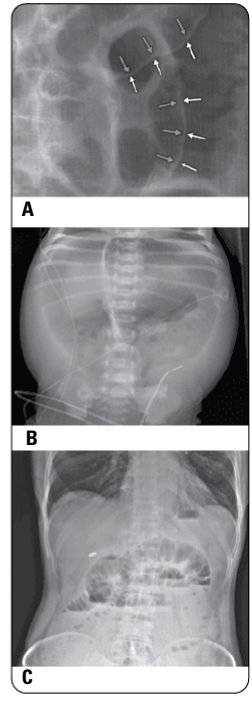

Figure 17. (A) "Rigler's" sign (B) "football" sign (C) "string of pearls" sign
Rigler's sign courtesy of Dr Jeremy Jones, Radiopedia.org, rID: 8041. Prof Frank Gaillard https://radiopedia.org/cases/8041

Approach to Abdominal Computed Tomography

- look through all images in gestalt fashion to identify any obvious abnormalities
- look at each organ or structure individually, from top to bottom, evaluating the size and shape of each area of increased or decreased density
- evaluate the following:
  - soft tissue window
    - liver, gallbladder, spleen, and pancreas
    - adrenals, kidneys, ureters, and bladder
    - stomach, duodenum, small bowel mesentery, and colon/appendix
    - retroperitoneum (aorta, vena cava, and mesenteric vessels; look for adenopathy in vicinity of vessels)
    - peritoneal cavity for fluid or masses
    - abdominal wall and adjacent soft tissue
  - lung window
    - visible lung (bases)
  - bone window
    - vertebrae, spinal cord, and bony pelvis

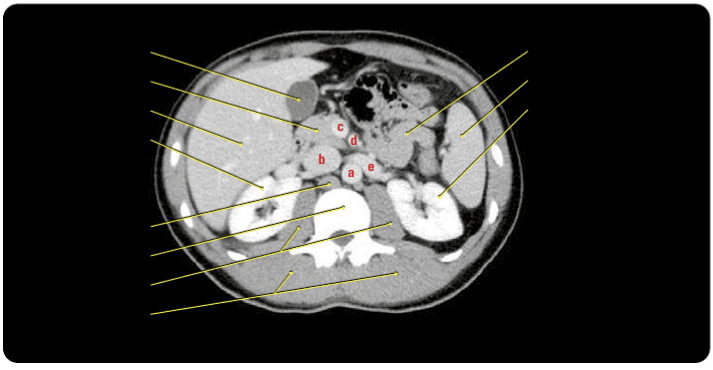

Figure 19. Axial abdominal computed tomography

CT and Bowel Obstruction

- cause of bowel obstruction is rarely found on plain films; CT is the best imaging modality
- the "3,6,9" rule is a very useful guide for determining when the bowel is dilated; the maximum diameter for the small bowel is 3 cm, for large bowel is 6 cm, and for cecum is 9 cm; this can also be useful to distinguish small and large bowel, and to assess for 'impending' cecal perforation (e.g. post-untreated Ogilvie's syndrome)
- closed-loop obstruction: an obstruction in two locations (usually small bowel) creating a loop of bowel obstructed both proximally and distally; complications (e.g. ischemia, perforation, necrosis) may occur quickly

CT Colonography (Virtual Colonoscopy)

- emerging imaging technique for evaluation of intraluminal colonic masses (i.e. polyps, tumours)
- two CT scans of the abdomen (prone and supine) after the instillation of carbon dioxide into a prepped colon
- computer reconstruction of 2D CT images into a 3D intraluminal view of the colon
- lesions seen on 3D images correlated with 2D axial images
- indications: surveillance in low-risk patients, incomplete colonoscopy, or staging of obstructing colonic lesions

Contrast Studies

Table 10. Types of Contrast Studies

Study	Organ	Procedure Description	Assessment	Findings
Cine Esophagogram	Cervical esophagus	Contrast agent swallowed Recorded for later playback and analysis	Dysphagia, swallowing incoordination, recurrent aspiration, postoperative cleft palate repair	Aspiration, webs (partial occlusion), Zenker's diverticulum, cricopharyngeal bar, laryngeal tumour
Barium Swallow	Thoracic esophagus	Contrast agent swallowed under fluoroscopy, selective images captured	Dysphagia, rule out GERD, post-esophageal surgery	Achalasia, hiatus hernia, esophagitis, cancer, esophageal tear
Upper GI Series	Thoracic esophagus, stomach, and duodenum	Double contrast study: 1. Barium to coat mucosa 2. Gas pills for distention Patient NPO after midnight	Dyspepsia, investigate possible upper GI bleed, weight loss/anemia, post-gastric surgery	Ulcers, neoplasms, filling defects
Enterography and Enteroclysis (MRI or CT)	Entire small bowel	Enterography: patient drinks 1-2 L of sorbitol, psyllium, or barium solution to distend small bowel Enteroclysis: NJ tube used to pump barium, psyllium, or sorbitol contrast media directly into small bowel	IBD, malabsorption, weight loss/anemia, Meckel's diverticulum	Neoplasms, IBD, malabsorption, infection

Colorectal Cancer: CT Colonography and Colonoscopy for Detection-Systematic Review and Meta-Analysis
Radiology 2011;259:393-405
Purpose:To assess the sensitivity of computed tomography colonography (CTC) and optical colonoscopy (OC) for colorectal cancer (CRC) detection.
Methods: Systematic review and meta-analysis of diagnostic studies evaluating CTC detection of CRC based on a priori eligibility criteria, in particular requiring both OC and histological confirmation of disease. Studies that also assessed true-positive and false-negative diagnoses with OC were used to calculate OC sensitivity. Sensitivity of CT colonography and OC for CRC was the main outcome.
Results: 49 studies on 11,151 patients undergoing diagnostic study for detection of CRC were included. CTC has a sensitivity of 96.1% (95% CI 93.8%, 97.7%) and OC has a sensitivity of 94.7% (95% CI 90.4%, 97.2%) for the detection of CRC.
Conclusion: CTC is highly sensitive for the detection of CRC and may be a better modality for the initial investigation of suspected CRC, assuming reasonable specificity.

Specific Visceral Organ Imaging

- for the management of urgent and emergent peritoneal masses

Liver

- U/S: assessment of cysts, abscesses, tumours, biliary tree
- CT ± IV: most popular procedure for imaging the liver parenchyma (primary liver tumours, metastases, cysts, abscesses, trauma, cirrhosis)
- MRI: excellent in evaluation of primary liver tumours, liver metastases, other parenchymal conditions; particularly helpful in differentiating common benign hepatic hemangiomas from primary liver tumours and metastases
- elastography: measures shear wave velocity by U/S (FibroScan) or MRI (MR elastography) to non-invasively quantify liver fibrosis
- findings:
  - advanced cirrhosis: liver small and irregular (fibrous scarring, segmental atrophy, regenerating nodules)
  - porto-systemic shunts: caput medusae, esophageal varices, spontaneous spleno-renal shunt
  - U/S: cirrhosis appears nodular and hyperechoic with irregular areas of atrophy of the right lobe and hypertrophy of the caudate or left lobes
  - CT: fatty infiltration appears hypodense
- some masses require contrast to be visualized
- upon identifying a liver lesion on imaging (e.g. U/S), the follow-up imaging modality should be CT or MRI. CT would be four-phase non-contrast, arterial, venous, and delayed to distinguish the common benign liver lesion hemangioma from other tumours

Spleen

- U/S, CT, nuclear medicine scan (nuclear medicine only to distinguish ectopic splenic tissue from enhancing tumours)
- CT for splenic trauma (hemorrhage)

See Landmark Medical Imaging Trials table for more information on the AMACING trial comparing hydration to no hydration in the incidence of contrast-induced nephropathy.

Normal liver appears more dense than spleen on CT. If less dense, suspect fatty infiltration

Liver Mass DDx

5 Hs
HCC
Hydatid cyst
Hemangioma
Hepatic adenoma
Hyperplasia (focal nodular)

Table 11. Imaging of Liver Masses

	U/S	CT
Benign Mass		
Hepatic Adenoma	Well-defined mass with hyperechoic areas due to hemorrhage	Well-defined hypervascular lesion with enlarged central vessel becoming slightly isoattenuating in venous phase
Hemangioma	Homogeneous hyperechoic mass	Peripheral globular enhancement in arterial phase scans; central filling and persistent enhancement on delayed scans
Focal Nodular Hyperplasia	Well-defined mass, central scar seen in 50% of cases	Hypervascular mass in arterial phase and isoattenuation to liver in portal venous phase
Abscess	Ill-defined, irregular margin, hypoechoic contents	Low attenuation lesion with an irregular enhancing wall
Hydatid Cyst	Simple/multiloculated cyst	Low attenuation simple or multiloculated cyst; calcification
Malignant Mass		
HCC	Single/multiple masses, or diffuse infiltration	Hypervascular; enhances in arterial and washes out in venous phase with portal venous tumour thrombus
Metastases	Multiple masses of variable echotexture	Usually low attenuation on contrast-enhanced scan

Pancreas

- tumours
  - U/S: mass is more echogenic than normal pancreatic tissue
  - CT: preferred modality for diagnosis/staging
- ductal dilation secondary to stone/tumour
  - MRCP: imaging of ductal system using MRI cholangiography; no therapeutic potential
  - ERCP: endoscopic injection of dye into the biliary tree and x-ray imaging to assess pancreatic and biliary ducts; therapeutic potential (stent placement, stone retrieval)
    - acute pancreatitis is a complication in 5% of diagnostic procedures and 10% of therapeutic procedures

Biliary Tree

- U/S: bile ducts usually visualized only if dilated, secondary to obstruction (e.g. choledocholithiasis, benign stricture, mass)
- CT: dilated intrahepatic ductules seen as branching, tubular structures following pathway of portal venous system
- MRCP, ERCP, PTC: further evaluation of obstruction and possible intervention

"itis" Imaging

Acute Cholecystitis

- pathogenesis: inflammation of gallbladder resulting from sustained gallstone impaction in cystic duct, or in the case of acalculous cholecystitis, due to gallbladder ischemia or cholestasis (see General and Thoracic Surgery, GS56)
- best imaging modality: U/S (best sensitivity and specificity); nuclear medicine (HIDA scan) can help diagnose cases of acalculous or chronic cholecystitis
- findings: most sensitive findings are presence of gallstones and positive sonographic Murphy's sign (tenderness from pressure of U/S probe over visualized gallbladder). Secondary findings include thickened gallbladder wall (>3 mm), dilated gallbladder, and pericholecystic fluid
- management: admit, NPO, IV fluids, analgesia, cefazolin, and early laparoscopic cholecystectomy

Acute Appendicitis

- pathogenesis: luminal obstruction → bacterial overgrowth → inflammation/swelling → increased pressure → localized ischemia → gangrene/perforation → localized abscess or peritonitis (see General and Thoracic Surgery, GS35)
- best imaging modality: U/S or CT
- findings:
  - U/S: thick-walled appendix, appendicolith, dilated fluid-filled appendix, non-compressible; may also demonstrate signs of other causes of RLQ pain (e.g. ovarian abscess, IBD, ectopic pregnancy)
  - CT: enlargement of appendix (>6 mm in outer diameter), enhancement of appendiceal wall, adjacent inflammatory stranding, appendicolith; also facilitates percutaneous abscess drainage
- management: admit, NPO, IV fluids, analgesia, cefazolin + metronidazole, and appendectomy

Acute Diverticulitis

- pathogenesis: erosion of the intestinal wall (most commonly rectosigmoid) by increased intraluminal pressure or inspissated food particles → inflammation and focal necrosis → micro- or macroscopic perforation (see General and Thoracic Surgery, GS39)
- best imaging modality: CT, although U/S is sometimes used
- contrast: oral and rectal contrast given before CT to opacify bowel

Revised Estimates of Diagnostic Test Sensitivity and Specificity in Suspected Biliary Tract Disease
Arch Intern Med 1998;154:2573-2581
Purpose: To assess the sensitivity and specificity of tests used to diagnose cholelithiasis and acute cholecystitis, including U/S, oral cholecystography, radionucleotide scanning with Technetium, MRI, or CT.
Methods: Meta-analysis of studies evaluating the use of different imaging modalities in the diagnosis of biliary tract disease. Main outcomes were sensitivity and specificity of the different imaging modalities, using the gold standard of surgery, autopsy, or 3 mo clinical follow-up for cholelithiasis. For acute cholecystitis, pathologic findings, confirmation of an alternate disease, or clinical resolution during hospitalization for cholecystitis were used as the standard.
Results: Thirty studies were included. For evaluating cholelithiasis, U/S had the best unadjusted sensitivity (0.97; 95% CI 0.95-0.99) and specificity (0.95, 0.88-1.00) and adjusted (for verification bias) sensitivity (0.84; 0.76-0.92) and specificity (0.99; 95% CI 0.97-1.00). For evaluating acute cholecystitis, radionucleotide scanning has the best sensitivity (0.97; 0.96-0.98) and specificity (0.90; 0.86-0.95).
Conclusion: U/S is the test of choice for diagnosing cholelithiasis and radionucleotide scanning is the superior test for diagnosing acute cholecystitis.

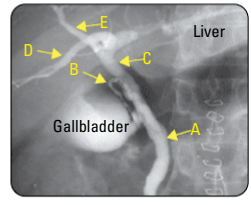

Figure 20. ERCP: biliary tree (A) common bile duct (B) cystic duct (C) common hepatic duct (D) right hepatic duct (E) left hepatic duct

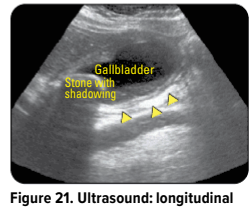

Figure 21. Ultrasound: longitudinal view of an inflamed gallbladder Arrowheads show thickened walls and pericholecystic fluid

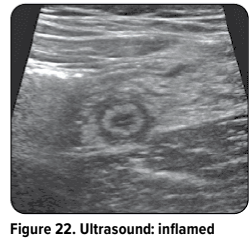

Figure 22. Ultrasound: inflamed appendix

- findings:
  - cardinal signs: thickened wall, mesenteric infiltration, gas-filled diverticula, abscess
  - CT can be used for percutaneous abscess drainage before or in lieu of surgical intervention
  - sometimes difficult to distinguish from perforated cancer (send abscess fluid for cytology and follow up with colonoscopy)
  - if chronic, may see fistula (most common to bladder) or sinus tract (linear or branching structures)
- management: ranges from antibiotic treatment to surgical intervention; can use imaging to follow progression

Acute Pancreatitis
- pathogenesis: activation of proteolytic enzymes within pancreatic cells leading to local and systemic inflammatory response (see Gastroenterology, G48); a clinical/biochemical diagnosis
- best imaging modality: imaging used to support diagnosis and evaluate for complications (diagnosis cannot be excluded by imaging alone)
  - U/S good for screening and follow-up
  - CT is useful in advanced stages and in assessing for complications (1st line imaging test)
- findings:
  - U/S: hypoechoic enlarged pancreas (if ileus present, gas obscures pancreas)
  - CT: enlarged pancreas, edema, fat stranding with indistinct fat planes, mesenteric and Gerota's fascia (renal fascia) thickening, pseudocyst in lesser sac, abscess (gas or thick-walled fluid collection), pancreatic necrosis (low attenuation gas-containing non-enhancing pancreatic tissue), hemorrhage
- management: supportive therapy
  - CT-guided needle aspiration and/or drainage of abscess when clinically indicated
  - pseudocyst may be followed by CT and drained if symptomatic

Chronic Pancreatitis
- pathogenesis: (see Gastroenterology, G50)
- best imaging modality: MRCP (can show calcification and duct obstruction)
- findings: U/S, CT scan, and MRI may show calcifications, ductal dilatation, enlargement of the pancreas, and fluid collections (e.g. pseudocysts) adjacent to the gland

Angiography of Gastrointestinal Tract

- anatomy of the arterial branches of the GI tract
  - celiac artery: hepatic, splenic, gastroduodenal, left/right gastric
  - superior mesenteric artery: jejunal, ileal, ileo-colic, right colic, middle colic
  - inferior mesenteric artery: left colic, superior rectal
- imaging modalities
  - conventional angiogram: invasive (usual approach via femoral puncture), catheter used
    - flush aortography: catheter injection into abdominal aorta, followed by selective arteriography of individual vessels
  - CT angiogram: modality of choice, non-invasive using IV contrast (no catheterization required)

Genitourinary System and Adrenal

Urological Imaging

Kidney, Ureter, and Bladder (KUB) X-Ray
- a frontal supine radiograph of the abdomen
- indication: useful in evaluation of radiopaque renal stones (exceptions: uric acid and indinavir stones), indwelling ureteric stents/catheters, and foreign bodies in abdomen
- findings: addition of IV contrast excreted by the kidney (intravenous urogram) allows better visualization of the urinary tract but has been largely replaced by CT urography

Abdominal CT

Renal Masses
- Bosniak classification for cystic renal masses
- class I-II: benign and can be disregarded
- class IIF: should be followed
- class III-IV: suspicious for malignancy, requiring additional workup

Computed Tomography and Ultrasonography to Detect Acute Appendicitis in Adults and Adolescents
Ann Intern Med 2004;141:537-546
Purpose: To review the diagnostic accuracy of CT and U/S in the diagnosis of acute appendicitis.
Methods: Meta-analysis of prospective studies evaluating the use of CT or U/S, followed by surgical or clinical follow-up in patients with suspected appendicitis. Patients ≥14 yr with a clinical suspicion of appendicitis were eligible. Sensitivity and specificity using surgery or clinical follow-up as the gold standard were the main outcomes studied.
Results: Twenty-two studies were included. CT (12 studies) had an overall sensitivity of 0.94 (95% CI 0.91-0.95) and a specificity of 0.95 (0.93-0.96). U/S (14 studies) had an overall sensitivity of 0.86 (0.83-0.88) and a specificity of 0.81 (0.78-0.84).
Conclusion: CT is more accurate for diagnosing appendicitis in adults and adolescents, although verification bias and inappropriate blinding of reference standards were noted in the included studies.

Ultrasound, Computed Tomography or Magnetic Resonance Imaging for Acute Appendicitis in Children
Pediatr Radiol 2017;47:186-196
Purpose: Compare the accuracies of U/S, CT, and MRI for clinically suspected acute appendicitis in children.
Methods: Search and meta-analysis. The sensitivity, specificity, and the area under the curve of summary receiver operating characteristics were calculated and compared.
Results: 19 studies of U/S, 6 studies of CT, and 4 studies of MRI. The analysis showed that the area under the receiver operator characteristics curve of MRI (0.995) was a little higher than that of US (0.987) and CT (0.982; P>0.05).
Conclusion: US, CT, and MRI have high diagnostic accuracies of clinically suspected acute appendicitis in children overall with no significant difference.

Angiography requires active blood loss
1-1.5 mL/min under optimal conditions for a bleeding site to be visualized in cases of lower GI bleeding

Imaging Modality Based on Presentation
Acute testicular pain = Doppler, U/S
Amenorrhea = U/S, MRI (brain)
Bloating = Plain film/CT (if abnormal)
Flank pain = U/S, CT
Hematuria = U/S, Cystoscopy, CT
Infertility = HSG, MRI
Lower abdominal mass = U/S, CT
Lower abdominal pain = U/S, CT
Renal colic = U/S, KUB, CT
Testicular mass = U/S
Urethral stricture = Urethrogram

Table 12. Bosniak Classification for Cystic Renal Masses

Classes	Definition
Simple Renal Cysts	
Class I	Fluid-attenuating well-defined lesion, no septation, no calcification, no solid components, hairline thin wall
Class II	Same as class I + fine calcification or moderately thickened calcification in septae or walls; also includes hyperdense cysts (<3 cm) that do not enhance with contrast
	*Class IIF: multiple hairline-thin septa with minimal thickening, no enhancing soft tissue components, completely intrarenal non-enhancing high-attenuating renal lesions >3 cm
Complex Renal Cysts	
Class III	Thick irregular walls ± calcifications ± septated, enhancing walls, or septa with contrast
Renal Cell Carcinoma	
Class IV	Same as class III + soft tissue enhancement with contrast (defined as >10 Hounsfield unit increase, characterizing vascularity) with de-enhancement in venous phase ± areas of necrosis

- plain CT KUB indications: general imaging of renal anatomy, renal colic symptoms, assessment of renal calculi (size and location) and potential sequelae (infection and obstruction), and hydronephrosis prior to urological treatment
- CT urography indications: investigation of cause of hematuria, detailed assessment of urinary tracts (excretory phase), high sensitivity (95%) for uroepithelial malignancies of the upper urinary tracts, assessment of renal calculi
  - phases: unenhanced, excretory
- renal triphasic CT indications: standard imaging for renal masses, allows accurate assessment of renal arteries and veins, better characterization of suspicious renal masses – especially in differentiating renal cell carcinoma from more benign masses, and preoperative staging
  - phases: unenhanced, arterial and venous (nephrographic), excretory

Ultrasound

- indications: initial study for evaluation of kidney size and nature of renal masses (solid vs. cystic masses, simple vs. complicated cysts); modality of choice for screening patients with suspected hydronephrosis (no IV contrast injection, no radiation exposure, and can be used in patients with renal failure); TRUS useful to evaluate prostate gland and guide biopsies; Doppler U/S to assess renal vasculature
- findings: solid renal masses are echogenic (bright on U/S), cystic renal masses have smooth well-defined walls with anechoic interior (dark on U/S), and complicated cysts have internal echoes within a thickened, irregular wall

Retrograde Pyelography

- indications: visualize the urinary collecting system via a cystoscope, ureteral catheterization, and retrograde injection of contrast medium, visualized by radiography or fluoroscopy; ordered when the intrarenal collecting system and ureters cannot be opacified using intravenous techniques (patient with impaired renal function, high grade obstruction, or allergy to IV contrast)
- findings: only yields information about the collecting systems (renal pelvis and associated structures), no information regarding the parenchyma of the kidney

Voiding Cystourethrogram

- bladder filled with contrast to the point where voiding is triggered
- fluoroscopy (continuous, real-time x-ray) to visualize bladder during voiding
- indications: males or young females with recurrent UTIs, hydronephrosis, hydroureter, suspected lower urinary tract obstruction, suspected bladder trauma, or vesicoureteral reflux
- findings: evaluation of bladder contractility and evidence of vesicoureteral reflux

Retrograde Urethrogram

- a small Foley catheter placed into penile urethral opening, followed by instillation of contrast and radiographic imaging
- indications: used mainly to study strictures or trauma to the male urethra; first-line study if signs of urethral injury are present (i.e. trauma with blood at the urethral meatus, scrotal hematoma, or high-riding prostate)

MRI

- advantages: better contrast resolution and tissue discrimination, lack of exposure to ionizing radiation, safer contrast, ability to obtain imaging directly from multiple planes (coronal, sagittal, oblique)
- indications: indicated over CT for depiction of renal masses in patients with previous nephron-sparing surgery, patients requiring serial follow-up (less radiation dosage), patients with reduced renal function, patients with solitary kidneys, clinical staging of prostate cancer (endorectal coil MRI)

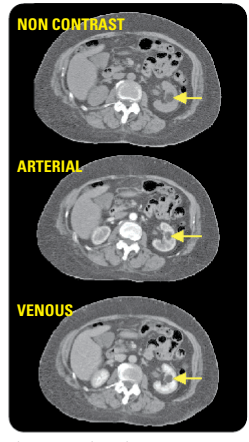

Figure 23. Triphasic CT of an angiomyolipoma: showing fat density with non-contrast scan, mildly enhancing with contrast

Ultrasonography vs. Computed Tomography for Suspected Nephrolithiasis
NEJM 2014;371:1100-1110
Purpose: Investigate whether the initial imaging method for patients with suspected nephrolithiasis should be CT or U/S.
Methods: Multicenter, pragmatic, comparative effectiveness trial, randomly assigned patients in the ED with suspected nephrolithiasis to undergo initial diagnostic ultrasonography performed by an emergency physician (POCUS), U/S performed by a radiologist, or abdominal CT. Comparisons: 30 d incidence of high-risk diagnoses with complications that could be related to missed or delayed diagnosis and the 6 mo cumulative radiation exposure.
Results: A total of 2759 patients underwent randomization. The incidence of high-risk diagnoses with complications in the first 30 d did not vary according to imaging method. The mean 6 mo cumulative radiation exposure was significantly lower in the U/S groups. Adverse events were similar across groups. Return ED visits, hospitalizations, and diagnostic accuracy did not differ significantly among the groups.
Conclusions: Initial ultrasonography was associated with lower cumulative radiation exposure than initial CT, without significant differences in high-risk diagnoses with complications, serious adverse events, pain scores, return ED visits, or hospitalizations.

Renal Nuclear Scan

Table 13. Renal Scan Tests

Type of Test	Uses	Radionuclide
Renogram	Assess renal function and collecting system: evaluation of renal failure, workup of urinary tract obstruction and renovascular HTN, investigation of renal transplant	IV^{99} mTc-pentetate (DTPA) or mertiatide (MAG3), and imaged at 1-3 s intervals with a γ-camera over the first 60 s to assess perfusion
Morphological	Assess renal anatomy: investigation of pyelonephritis and cortical scars	^{99m}Tc-DMSA ^{99m}Tc-glucoheptonate

Gynecological Imaging

Ultrasound
- transabdominal and transvaginal are the primary modalities, and are indicated for different scenarios
- transabdominal requires a full bladder to push out air-containing loops of bowel
  - indications: good initial investigation for suspected pelvic pathology
- TVUS provides a panoramic pelvic view and enhanced detail of deeper/smaller structures by allowing use of higher frequency sound waves due to reduced distances
  - indications: improved assessment of ovaries, first trimester development, and ectopic pregnancy

Hysterosalpingogram
- performed by x-ray images of the pelvis after cannulation of the cervix and subsequent injection of opacifying agent
- indications: useful for assessing pathology of the uterine cavity and fallopian tubes, evaluating uterine abnormalities (e.g. bicornuate uterus), or evaluation of fertility (absence of flow from tubes to peritoneal cavity indicates obstruction)

CT/MRI
- indications: evaluating pelvic structures, especially those adjacent to the adnexa and uterus
- invaluable for staging gynecological malignancies and detecting recurrence

Sonohysterogram
- transcervical saline introduction into uterine cavity to provide enhanced endometrial visualization during TVUS examination
- indications: abnormal uterine bleeding, uterine cavity abnormalities that are suspected or noted on TVUS (e.g. leiomyomas, polyps, synechiae), congenital abnormalities of the uterine cavity, infertility, recurrent pregnancy loss
- contraindications: pregnancy, pelvic infection

Table 14. Typical and Atypical Findings on a Sonohysterogram

Finding	Typical	Atypical
Polyps	A well-defined, homogeneous, polypoid lesion isoechoic to the endometrium with preservation of the endometrial-myometrial interface	Cystic components, multiple polyps, broad base, hypoechogenicity, or heterogeneity
Leiomyoma	Well-defined, broad-based, hypoechoic, solid masses with shadowing. Overlying layer of endometrium is echogenic and distorts the endometrial-myometrial interface	Pedunculation or multilobulated surface
Hyperplasia and Cancer	Diffuse echogenic endometrial thickening without focal abnormality, although focal lesions can occur Endometrial cancer is typically a diffuse process, but early cases can be focal and appear as a polypoid mass	
Adhesions	Mobile, thin, echogenic bands that cut across the endometrial cavity	Thick, broad-based bands that can completely obliterate the endometrial cavity, as in Asherman's syndrome

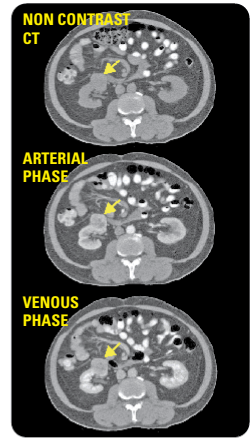

Figure 24. Triphasic CT of a renal cell carcinoma: showing arterial enhancing right renal lesion with venous washout (shunting)

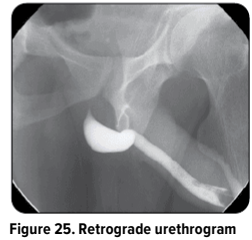

Figure 25. Retrograde urethrogram demonstrating stricture in the membranous urethra

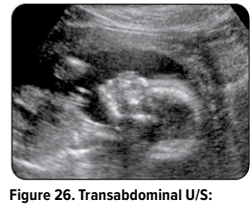

Figure 26. Transabdominal U/S: pregnancy, 18 wk fetus

Pregnancy should always be ruled out by β-hCG before CT of a female pelvis (or any organ system) is performed

Figure 27. Hysterosalpingogram: left hydrosalpinx

Adrenal Mass

- imaging modality: most often identified on CT scan as 'incidentaloma,' can also use CT/MRI to distinguish benign from malignant masses

Table 15. Adrenal Mass Findings on CT and MRI

Factors	Adrenocortical Adenoma	Adrenocortical Carcinoma	Pheochromocytoma	Metastasis
Diameter (CT)	Usually ≤3 cm	Usually ≥4 cm	Usually >3 cm	Variable around <3 cm
Shape (CT)	Smooth margins and round/oval	Irregular with unclear margins	Round/oval with clear margins	Oval/irregular with unclear margins
Texture (CT)	Homogeneous	Heterogeneous with mixed densities	Heterogeneous with cystic areas	Heterogeneous with mixed densities
Vascularity (CT)	Not highly vascular	Usually vascular	Usually vascular	Usually vascular
Washout of Contrast Medium on CT	≥50% at 10 min	<50% at 10 min	<50% at 10 min	<50% at 10 min
Growth	Stable or very slow (<1 cm/yr)	Usually rapid (>2 cm/yr)	Slow (0.5-1 cm/yr)	Variable
Other Findings	Usually low density due to intracellular fat	Necrosis, calcifications, and hemorrhage	Hemorrhage	Occasionally hemorrhage
MRI on T2 Weighted Imaging	Isointense in relation to liver	Hyperintense in relation to liver	Markedly hyperintense in relation to liver	Hyperintense in relation to liver

Neuroradiology

Skull Films

- rarely performed, generally not indicated for non-penetrating head trauma
- indications: screening for destructive bony lesions (e.g. metastases), metabolic disease, skull anomalies, postoperative changes and confirmation of hardware placement, skeletal surveys, multiple myeloma

CT

- CT is often the first line modality for most neuropathology, even in situations where MRI would lead to better characterization
- CT is frequently the initial study performed because of its speed, availability, and lower cost
  - acute craniofacial trauma: CT is best for visualizing "bone and blood;" use MRI when CT fails to detect an abnormality despite strong clinical suspicion
  - acute stroke: MRI ideal, CT most frequently used
  - acute headache with focal neurologic signs
  - suspected hemorrhage (epidural, subdural, subarachnoid, intraparenchymal)
  - suspected hydrocephalus
- vascular structures and areas of blood-brain barrier impairment are bright (e.g. hyperdense or enhancing) with contrast injection
- danger signs on head CT: space-occupying process, hemorrhage, edema, mass effect, midline shift, uncal and tonsillar herniation, loss of grey-white matter differentiation, hydrocephalus

Myelography

- introduction of water-soluble, low-osmotic contrast media into subarachnoid space via lumbar puncture followed by x-ray
- largely replaced by MRI or CT myelogram
- indications: excellent study for disc herniation, traumatic nerve root avulsion, patients with contraindication to MRI, extensive hardware from spinal surgery that may create MRI artifacts

MRI

- indications: finer neuroanatomic definition, better grey-white matter differentiation (especially T1-weighted series), better evaluation of edema extent (better tumour detection), allows evaluation of structures obscured by bony artifacts on CT (posterior fossa structures), multiplanar imaging helpful in preoperative assessment

Cerebral Angiography/CT Angiography/MR Angiography

- indications: evaluation of vascular lesions such as atherosclerotic disease, aneurysms, vascular malformations, arterial dissections
- conventional DSA remains the gold standard for the assessment of neck and intracranial vessels; however, it is an invasive procedure requiring arterial (typically femoral) access and catheter manipulation, which confers risk of vessel injury (e.g. dissection, occlusion, vasospasm, emboli)
- MRA methods (phase contrast, time of flight, gadolinium-enhanced) and CTA are much less invasive without risk to intracranial or neck vessels
- MRA and CTA are often used first for the assessment of suspected TIA, subarachnoid hemorrhage, vasospasm, or aneurysms

Modality Based on Neuropathology Presentation

- Cognitive decline = CT
- Cord compression = MRI
- Decreased level of consciousness = CT
- Fish bone/other swallowed foreign body = CT
- Low back pain, radiculopathy = MRI
- Multiple sclerosis = MRI
- Neck infection = CT
- Orbital infection = CT
- Rule out bleed = CT
- Rule out aneurysm = CTA, MRA
- Seizure = CT
- Sinusitis = CT
- Stroke = CT, MRI
- Trauma = CT
- Weakness, systemically unwell = CT

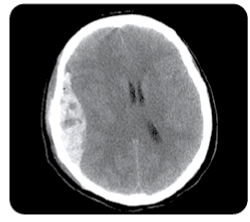

Figure 28. Epidural hematoma

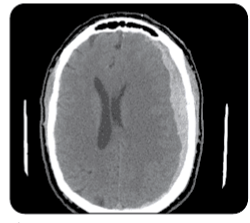

Figure 29. Subdural hematoma

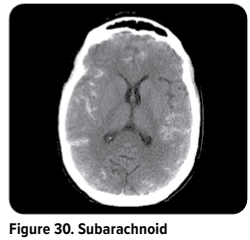

Figure 30. Subarachnoid hemorrhage

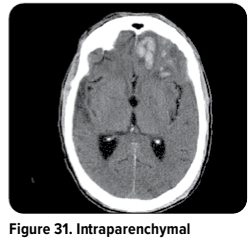

Figure 31. Intraparenchymal hemorrhage

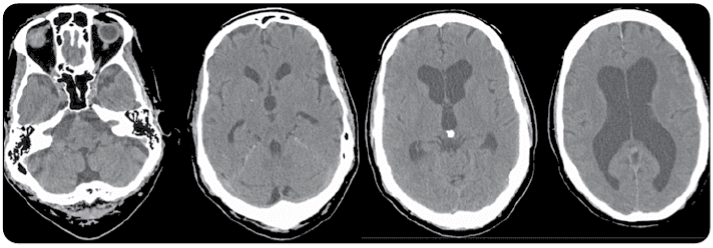

Figure 32. Hydrocephalus: ventricular dilatation (may see periventricular low attenuation due to transependymal CSF flow)

Table 16. Two Types of Hydrocephalus

Type	Cause
Communicating/Extraventricular	Impaired CSF reabsorption with unobstructed flow in ventricular system; imaging shows all ventricles dilated
Non-Communicating	Obstruction within the ventricular system (e.g. mass obstructing the aqueduct or foramen of Monro); imaging shows dilatation of ventricles proximal to the obstruction

Nuclear Medicine

- SPECT imaging using ^{99}mTc-exametazime (HMPAO) and ^{99}mTc-bicisate (ECD) assesses cerebral blood flow, as radionuclides diffuse rapidly across the blood-brain barrier and become trapped within neurons at a magnitude proportional to cerebral blood flow
- ^{18}FDG PET imaging assesses cerebral metabolic activity
- indications: differentiation of residual tumour vs. radiation necrosis; localization of epileptic seizure foci, and evaluation of atypical dementia

Approach to Head Computed Tomography

- think anatomically, work from superficial to deep
- scan: confirm the time and imaging of the correct patient, whether contrast was used, patient alignment, and presence of artifact
- skin/soft tissue: examine the soft tissue superficial to the skull for thickening suggestive of hematoma or edema; also evaluate the ear, orbital contents (globe, fat, muscles), parotid glands, muscles of mastication (masseter, temporalis, pterygoids), visualize pharynx
- bone and airspace (use the bone window): check calvarium, visualize mandible, visualize C-spine (usually C1 and maybe part of C2) for fractures, absent bone, lytic/sclerotic lesions; inspect sinuses and mastoid air cells for fractures or opacity that may suggest fluid, pus, blood, or tumour; status of the orbital floor in cases of facial trauma (coronal series best)
- dura and subdural space: crescent-shaped hyperdensity in the subdural space suggests subdural hematoma; lentiform hyperdensity in the epidural space suggests epidural hematoma; check symmetry of dural thickness, where increased thickness may suggest the presence of blood
- parenchyma: asymmetry of the parenchyma suggests midline shift; poor contrast between grey and white matter suggests possible infarction, tumour, edema, infection, or contusion; a hyperdensity in the parenchyma suggests an enhancing lesions, intracerebral hemorrhage, or calcification; if central grey matter nuclei (e.g. globus pallidus, putamen, internal capsule) are not visible, suspect infarct, tumour, or infection
- ventricles/sulci/cisterns: examine position of ventricles for evidence of midline compression/shift; hyperdensities in the ventricles suggest ventricular/subdural hemorrhage; enlarged ventricles suggest hydrocephalus; obliteration of sulci may suggest presence of edema causing effacement, possible blood filling in the sulci, or tumour; cistern hyperdensities may suggest blood, pus, or tumour

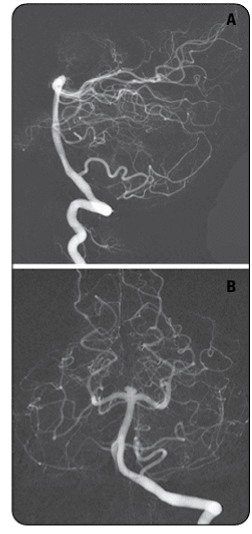

Figure 33. Sagittal (A) and coronal (B) views of the vertebrobasilar circulation (note the incidental basilar tip aneurysm)

Approach to the CT Head
Some = **S**can

TIAs are not associated with radiological findings

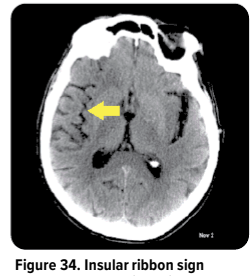

Figure 34. Insular ribbon sign (arrow): hypodensity of insular cortex representing early sign of infarction

Selected Pathology

- see Neurosurgery, NS4 for intracranial mass lesions
- see Neurosurgery, NS36 for head trauma and Plastic Surgery, PL31 for craniofacial injuries
- see Emergency Medicine, ER9 for spinal trauma
- see Neurosurgery, NS30 and Orthopedic Surgery, OR25 for degenerative spinal abnormalities

Cerebrovascular Disease (see Neurosurgery, NS22)

- pathogenesis of stroke: see Neurology, N51
- best imaging modality: MRI
- initial imaging modality: CT

Table 17. Temporal Findings of Infarction with CT and MRI

Time from Stroke Onset	CT	MRI
Hyperacute (0-24 h)	Usually normal within 6 h Edema (loss of grey-white matter differentiation – "insular ribbon sign," effacement of sulci, mass effect) Hyperattenuating artery "hyperdense MCA sign" representing intravascular thrombus/emboli may be seen in ischemic stroke Hyperattenuating acute blood surrounded by edema may be seen in hemorrhagic stroke	Hyperintensity on DWI within minutes of arterial occlusion due to restriction of water movement indicative of cytotoxic edema Hypointensity on ADC within minutes Hyperintensity on T2/FLAIR approximately 6 h after onset due to edema (loss of grey-white matter differentiation, effacement of sulci, mass effect)
Acute (24 h-1 wk)	Increasing edema (seen as hypoattenuation) may result in significant positive mass effect	Continued hyperintensity on DWI Hypointensity on ADC reaches nadir at 3-5 d and begins to increase Continued hyperintensity on T2/FLAIR
Subacute (1-3 wk)	Resolution of edema leads to increased attenuation of infarcted area that may regain near-normal density and mask stroke "fogging phenomenon"	Continued hyperintensity on DWI due to "T2 shine through" Intensity on ADC continues to rise, pseudo-normalizes at 10-15 d, and then surpasses that of surrounding normal tissue Continued hyperintensity on T2/FLAIR
Chronic (>3 wk)	Encephalomalacia (parenchymal volume loss) appears as hypoattenuation with negative mass effect	Hyperintensity on DWI/T2/FLAIR progressively decreases ADC intensity remains elevated

- carotid artery disease
  - best imaging modality: Duplex (Doppler U/S)
  - other modalities: MRA or CTA if carotid angioplasty or endarterectomy is under consideration (conventional angiography reserved for inadequate MRA or CTA)

Multiple Sclerosis (see Neurology, N55)

- best imaging modality: MRI has high sensitivity in diagnosing MS (>90%) but low specificity (71-74%)
- characteristic lesion locations: juxtacortical (grey-white junction), periventricular, infratentorial, and spinal cord
- cerebral lesions typical of MS:
  - involvement of the brainstem, cerebellum, and corpus callosum
  - "Dawson's fingers" refers to perivenular regions of demyelination that are seen to radiate outwards into the deep periventricular region
  - plaques usually hyperintense on T2, and hypointense on T1
  - perivascular and interstitial edema may be prominent; enhances with gadolinium contrast when actively inflamed
- spinal cord lesions typical of MS:
  - little or no cord swelling
  - less likely to enhance with gadolinium contrast
  - incomplete involvement of the cord in cross-section (dorsolateral common)

CNS Infections

- **meningitis**
  - pathogenesis: inflammation of the pia or arachnoid mater, most often secondary to hematogenous spread from infection or via direct seeding of organisms through areas not protected by the blood-brain barrier (choroid plexus or circumventricular organs)
  - pathogens include: *S. pneumoniae, H. influenzae, N. meningitidis, L. monocytogenes*
  - best imaging modality: MRI (T2-weighted/FLAIR)
  - findings:
    - meningeal enhancement (following the gyri/sulci and/or basal cisterns), hydrocephalus (communicating), cerebral swelling, subdural effusion
  - a normal MRI does not rule out leptomeningitis
- **herpes simplex encephalitis** (see Infectious Diseases, ID18)
  - pathogenesis: inflammation of the brain parenchyma secondary to infection with herpes simplex virus, asymmetrically affects the limbic regions of the brain (i.e. temporal lobes, orbitofrontal region, insula, and cingulate gyrus)
  - best imaging modality: MRI (T1- and T2-weighted)

DDx for Ring Enhancing Cerebral Lesion

MAGIC DR
Metastasis
Abscess
Glioblastoma multiforme
Infarction (subacute/chronic)
Contusion/hematoma
Demyelinating disease (e.g. MS)
Radiation necrosis

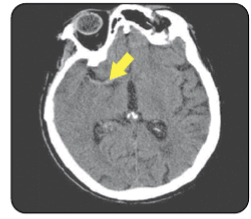

Figure 35. CT image of early infarct: hyperdense artery

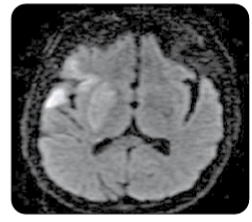

Figure 36. DWI of patient with right frontotemporal infarct

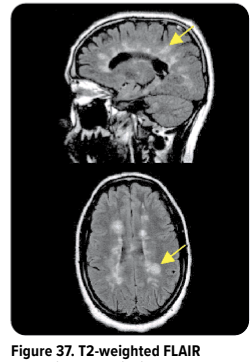

Figure 37. T2-weighted FLAIR (A) sagittal (B) axial images of multiple sclerosis with periventricular "Dawson's Fingers"

- findings:
  - acute (within 4-5 d): asymmetric high intensity lesions on T2 MRI in temporal and inferior frontal lobes strongly suggestive
  - CT may show hypodensity in temporal lobe and insula; rarely basal ganglia involvement
  - long-term may show parenchymal loss to affected areas
- DDx: infarct, tumour, status epilepticus, limbic encephalitis

- **cerebritis/cerebral abscess**
  - pathogenesis: an infection of the brain parenchyma (cerebritis) which can progress to a collection of pus (abscess), most frequently due to hematogenous spread of infectious organisms, commonly located in the distribution of the MCA
  - pathogens include: *S. aureus* (often in IV drug users, nosocomial), *Streptococcus*, Gram negative bacteria, *Bacteroides*
  - best imaging modality: MRI including DWI imaging series (abscess will be DWI positive); CT still used as a viable alternative
  - findings according to one of four stages of abscess formation:
    - early cerebritis (1-3 d): inflammatory infiltrate with necrotic centre, low intensity on T1, high intensity on T2
    - late cerebritis (4-9 d): ring enhancement may be present
    - early capsule (10-13 d): ring enhancement
    - late capsule (>14 d): well demarcated ring-enhancing lesion, low intensity core, with mass effect; considerable edema around the lesion, seen as hyperintensity on T2

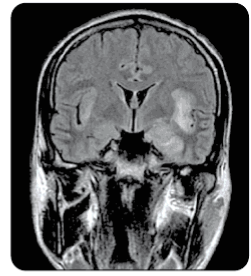

Figure 38. T2-weighted (FLAIR) coronal image of herpes simplex virus encephalitis affecting temporal lobes

Musculoskeletal System

Modalities

- see *Imaging Modalities*, MI2 for advantages and disadvantages of the following:

Plain Film/X-Ray
- usually initial study used in evaluation of bone and joint disorders
- indications: fractures and dislocations, arthritis, assessment of malunion or nonunion, orthopedic hardware, and bone lesions (initial)
- minimum of two orthogonal views (usually AP and lateral) to rule out a fracture/assess bone lesion
- image the joint proximal and distal to injury site to ensure there is no associated dislocation or second fracture site, particularly important with bony rings (e.g. radius/ulna, tibia/fibula)
- soft tissue assessment limited, but can identify joint effusions (elbow, knee), soft tissue gas (necrotizing fasciitis), and radiodense foreign bodies

CT
- evaluation of fine bony detail
- indications: preoperative assessment of complex, comminuted, intra-articular, or detection of radiographically-occult fractures including scaphoid, skull, spine, pelvis, midfoot, and calcaneus
- evaluation of soft tissue calcification/ossification and bone tumours

MRI
- indications: evaluation of internal derangement of joints (e.g. ligaments, joint capsule, menisci, labrum, cartilage), assessment of tendons and muscle injuries, characterization and staging of soft tissue and bony masses, infection of bone (osteomyelitis), occult fracture assessment

Ultrasound
- indications: tendon injury (e.g. rotator cuff, Achilles tendon), detection and characterization of soft tissue masses (i.e. cystic or solid), detection of foreign bodies, U/S-guided biopsy and injections, bone/joint evaluation pre-ossification (e.g. DDH in early months), dynamic imaging (i.e. snapping hip, extensor carpi ulnaris subluxation), small joint Doppler assessment for arthritis
- Doppler determines vascularity of structures

Nuclear Medicine (Primarily Bone Scan/Skeletal Scintigraphy)
- determines the location and extent of bony lesions using radiopharmaceuticals (^{99}mTc-methylene diphosphonate)
- increased binding when increased blood supply to bone and/or high bone turnover (active osteoblasts)
- indications: bone lesion characterization, occult fractures (spine, scaphoid, small bones), bone pain of unknown origin, staging or restaging of cancer with bony metastases (or primary bone cancer), imaging of polyarthritis, imaging of arthroplasty complications like loosening or infection, osteomyelitis imaging
  - when used to assess for osteomyelitis, usually done in combination with gallium or white blood cell scan
- DDx of positive bone scan: bone metastases (primary breast, prostate, lung, thyroid), primary bone tumour, arthritis, fracture, infection, anemia, Paget's disease
- caution: bone tumours that do not elicit osteoblastic response are often occult on bone scan (myeloma, highly vascular tumours such as RCC, or thyroid carcinoma)

Characterization of Rotator Cuff Tears: Ultrasound vs. Magnetic Resonance Imaging
Orthopedics 2017;40:e124-e130
Purpose: Determine whether U/S or MRI is more accurate and precise in evaluating the characteristics of full-thickness rotator cuff tears in a surgical population.
Methods: Review of 114 patients who underwent repair of a full-thickness rotator cuff tear over a 1 yr period. Of these patients, 61 had both preoperative MRI and U/S for review. Three radiologists evaluated each U/S and MRI in a randomized, blinded fashion on 2 occasions. Tear size, retraction status, muscle atrophy, and fatty infiltration were analyzed and compared between the 2 modalities.
Results: U/S measurements were statistically smaller in both tear size (P=0.001) and retraction status (P=0.001) compared with MRI. MRI showed greater interobserver reliability in assessment of tear size, retraction status, and atrophy.
Conclusion: Independent observers are more likely to agree on measurements of the characteristics of rotator cuff tears when using MRI compared with U/S. As tear size increases, the 2 image modalities show greater differences in measurement of tear size and retraction status. U/S may be best used to identify a tear, and MRI is superior for use in surgical planning for larger tears.

Approach to Bone X-Rays

- identification: name, MRN, age of patient, type of study, region of investigation
- soft tissues: swelling, calcification/ossification
- joints: alignment, joint space, presence of effusion, osteophytes, erosions, bone density, overall pattern, symmetry of affected joint
- bone: periosteum, cortex, medulla, trabeculae, density, articular surfaces, bone destruction, bone production, appearance of the edges or borders of any lesions

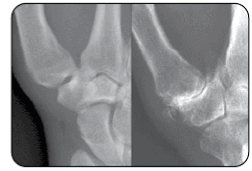

Figure 39. X-ray findings of first carpometacarpal joint: normal image (left) and osteoarthritis (right) with joint space narrowing and subchondral sclerosis

Trauma

Fracture/Dislocation

- description of fractures
- site of fracture (bone, region of bone, intra-articular vs. extra-articular)
- pattern of fracture line (simple vs. comminuted)
- displacement (distal fragment with reference to the proximal fragment)
- soft tissue involvement (calcification, gas, foreign bodies)
- type of fracture (stress vs. pathologic)
- for specific fracture descriptions and characteristics, see Orthopedic Surgery, OR5

Arthritis

- see Rheumatology for radiographic features of specific arthritides

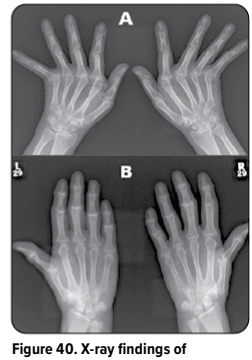

Figure 40. X-ray findings of rheumatoid arthritis (A) compared with osteoarthritis (B)

Bone and Soft Tissue Tumours

Bone Tumours

- benign bone lesions (e.g. hemangiomas, enostoses, enchondromas) are more common than malignant bone lesions
- primary bone tumours are rare after 3rd decade; metastases to bone are relatively common after 3rd decade
- MRI is helpful for detection, characterization, staging, soft tissue involvement, and surgical planning
- plain film is important for assessing pattern of destruction, mineralization, and aggressiveness
- biopsy may be required if no primary is identified, or suspect primary bone tumour
- may present with pathological fractures or bone pain
- most common metastatic bone tumours: breast, prostate, lung
- for specific bone tumours, see Orthopedic Surgery, OR50

Soft tissue Tumours

- soft tissue masses are most commonly benign
- common benign soft tissue masses include lipomas, benign peripheral nerve sheath tumours, and vascular malformations
- soft tissue sarcomas are uncommon but require urgent workup and specialized treatment
- U/S is helpful for differentiating lipoma from cyst from mass
- MRI is helpful for diagnostic workup
- if the mass is not clearly benign, biopsy or wide excision is required for diagnosis

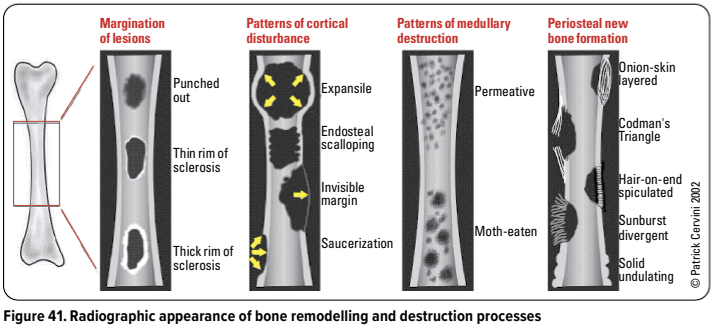

Figure 41. Radiographic appearance of bone remodelling and destruction processes

Lytic = decreased density
Sclerotic = increased density

Table 18. Distinguishing Benign from Malignant Bone Lesions on X-Ray

Benign	Malignant
No periosteal reaction or benign appearing reaction (e.g. uniform smooth periosteal thickening as seen in a healing fracture)	Acute periosteal reaction • Codman's triangle • "Onion skin" • "Sunburst"
Sharp, well-demarcated borders, narrow zone of transition (between lesion and normal bone, suggesting slow-growing lesion)	Poorly defined borders, with a wide zone of transition, or infiltrative (suggesting fast-growing lesion)
Well-developed bone formation	Varied bone formation
Intraosseous and even calcification	Extraosseous and irregular calcification
No soft tissue mass	Soft tissue mass present
No cortical destruction or uniform cortical destruction in some low grade and locally aggressive benign lesions	Aggressive cortical destruction or tumour infiltration without cortical destruction

Adapted from: Buckholtz RW, Heckman JD. Rockwood and Green's Fractures in Adults. Vol. 1. Philadelphia: Lippincott Williams & Wilkins, 2001. 558 p

Infection

Osteomyelitis

- modern workup includes MRI or x-ray
  - x-ray can detect osseous destruction seen with subacute osteomyelitis (>1 wk) or chronic change, and can detect lucencies surrounding infected orthopedic hardware
  - MRI is more sensitive, with loss of normal fatty T1 marrow signal diagnostic of esteomyelitis, and can also assess for extra-osseous soft tissue involvement or spread
- nuclear medicine (^{99}mTc, followed by ^{111}In-labeled white cell scan or gallium radioisotope scan) may be used where available, or in the setting of hardware

Septic Arthritis

- surgical emergency in large joints (i.e. hip)
- x-ray usually normal early
- aspiration required if concern for septic arthritis
- imaging modalities can detect joint fluid in some points, but imaging cannot rule out septic arthritis

Necrotizing Fasciitis

- surgical emergency
- X-ray can detect gas, but absence does not rule out necrotizing fasciitis
- in the perineum, referred to as Fournier's gangrene
- surgical referral required

Metabolic Bone Disease

Osteoporosis

- reduction in amount of normal bone mass; fewer and thinner trabeculae; diffuse process affecting all bones
  - typical sites of fragility fracture: spine, hip, pelvis, wrist, humerus, rib
- DEXA: gold standard for measuring bone mineral density, typically measured hip and lumbar spine
- Canadian Association of Radiologist and Osteoporosis Canada (CAROC) guidelines for use of DEXA: diagnosis, determining fracture risk/therapy, and monitoring
  - diagnosis driven by T-score: the number of standard deviations from the young adult mean, most clinically valuable
    - osteopenia: −2.5< T-score <−1
    - osteoporosis: T-score ≤-2.5
  - Z-score: the number of standard deviations from the age-matched mean, helpful in diagnosing secondary osteoporosis
  - risk of fracture: patients classified as low, medium, or high risk based on bone mineral density, age, history of previous fragility fractures, and steroid therapy. Presence of certain criteria such as hip or spine fragility fracture automatically places patients in the high risk category
- see Endocrinology, E46

Hyperparathyroidism

- most common cause is renal failure (secondary hyperparathyroidism)
- chondrocalcinosis is a common complication
- calcium crystal deposition in hyaline cartilage or fibrocartilage (including arteries and periarticular soft tissue)
- resorption of bone typically in hands (subperiosteal and at tufts), sacroiliac joints (subchondral), skull ("salt and pepper" appearance), subligamentous resorption (ischial tuberosity, trochanters, and clavicle), osteoclastoma (brown tumours)
- "rugger jersey spine": band-like osteosclerosis at superior/inferior margins of vertebral bodies

Paget's Disease
- abnormal remodelling involving single or multiple bones – especially skull, spine, pelvis
- 3 phases: 1st phase = lytic, 2nd phase = mixed (lytic/sclerotic), 3rd phase = sclerotic
- coarsening of the trabeculae with bone expansion
- bone softening/bowing
- bone scintigraphy will reveal high activity
- thickened cortex; widening of diploe in skull, osteoporosis circumscripta (lytic phase in skull); "blade of grass" sign (lytic phase in a long bone like the femur); "picture frame" appearance to vertebra (due to thickening and sclerosis of vertebral cortex)
- see Endocrinology, E50

Nuclear Medicine

Brain

- ^{99}mTc-exametazime (HMPAO) and ^{99}mTc-bicisate (ECD) imaging used in SPECT to assess cerebral blood flow and cellular metabolism
  - taken up predominantly in grey matter
  - used for dementia, traumatic brain injury; and to a lesser extent vasculitis, neuropsychiatric disorders, and occasionally stroke
- PET imaging to assesses metabolic activity
  - used for dementia imaging, grading and staging of brain tumours, occasionally for seizure disorder imaging, and vasculitis
- CSF imaging via intrathecal administration of ^{111}In DTPA
  - to evaluate CSF leak or to differentiate normal pressure hydrocephalus from brain atrophy
- CSF shunt evaluation for obstruction (most commonly ventriculoperitoneal) with sterile or pyrogen free ^{99}mTc (usually) or ^{111}In-DTPA

Thyroid

Radioactive Iodine Uptake (see Endocrinology, E27)
- index of thyroid function (trapping and organification of iodine)
- radioactive ^{123}I given PO to fasting patient (small quantity) and percentage of administered iodine taken up by thyroid is measured
- increased RAIU: toxic multinodular goitre, toxic adenoma, Graves' disease
- decreased RAIU: subacute thyroiditis, late Hashimoto's disease, exogenous thyroid hormone or iodine, falsely decreased in patient with recent radiographic contrast studies, high dietary iodine (e.g. seaweed, taking supplements containing desiccated thyroid)
- important – iodine uptake helps in the differential of hyperthyroidism only, not hypothyroidism

Thyroid Imaging (Scintiscan)
- ^{99}mTc-pertechnetate IV or radioactive iodine (^{123}I)
- provides functional anatomic detail
- hot (hyperfunctioning) lesions: usually benign (e.g. adenoma, toxic multinodular goitre), cancer unlikely (<1%) – No FNA
- cold (hypofunctioning) lesions: cancer must be considered until biopsy negative even though only 6-10% are cancerous – decision to biopsy should be based on clinical and sonographic features
- isointense (i.e. "warm" lesions): cancer must be considered as an isointense lesion; may represent cold nodules superimposed on normal tissue; if cyst suspected, correlate with U/S

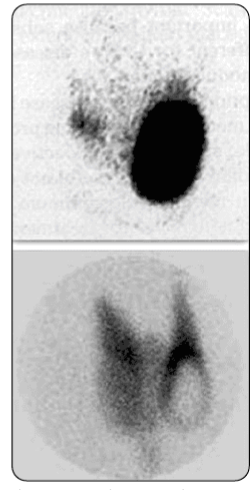

Figure 42. Multinodular goitre (top). Cold nodule (bottom)

Radioiodine Ablation
- ^{131}I for Graves' disease, multinodular goitre, thyroid cancer (in the case of thyroid cancer, ablation performed at higher dose and after thyroidectomy)
- serum thyroglobulin used to detect recurrent thyroid cancer in a patient who has received ablation
- advice should be given for patient-specific precautions to remain away from family members and caregivers to reduce radiation exposure after thyroid ablation, do not initiate pregnancy for 6 mo, small risk of exophthalmos, thyroid storm, secondary malignancy

Respiratory

V/Q Scan
- evaluate areas of lung in which there is a ventilation/perfusion mismatch
- ventilation scan – assess air flow within lungs
  - patient breathes radioactive gas (nebulized ^{99}mTc-DTPA, ^{133}Xe, or most commonly Technegas™) through a closed system, filling alveoli proportionally to ventilation
  - ventilation scan defects indicate: airway obstruction (i.e. air trapping), chronic lung disease, bronchospasm, tumour mass obstruction

- perfusion scan – assess blood circulation within lungs
  - radiotracer injected IV (^{99}mTc-MAA) → trapped in pulmonary capillaries (0.1% of arterioles occluded) according to blood flow
  - relatively contraindicated in severe pulmonary HTN, right-to-left shunt, previous history of pneumonectomy, and small children
- indicated to rule out PE
  - areas of lung that are well-ventilated but not perfused (unmatched defect) are suspicious for acute infarction
  - defects are wedge-shaped, extend to periphery, usually bilateral and multiple
  - useful in finding clinically important emboli
- modified V/Q scan (perfusion only, lower dose contrast) may be used for pregnant patients if CXR is normal or if there are ventilatory problems

Cardiac

Myocardial Perfusion Scan/Nuclear Stress Test

- indications: diagnose and assess treatment of coronary artery disease (CAD), preoperative risk stratification, viability testing before percutaneous intervention or bypass surgery
- ^{99}mTc-sestamibi or ^{99}mTc-tetrofosmin is injected: at peak exercise (85% max predicted heart rate by the Bruce protocol, chest pain, ECG changes), after persantine challenge (vasodilator), or after dobutamine infusion (chronotropic, again to 85% predicted heart rate)
- persistent defect (present at rest and stress) suggests infarction or myocardial scar
- reversible defect (only present during stress) suggests ischemia
- used to discriminate between reversible (ischemia) vs. irreversible (infarction) changes when other investigations are equivocal
- COURAGE trial indicates that patients with >10% ischemic myocardium benefit most from revascularization
- see Cardiology and Cardiac Surgery, C16

Radionuclide Ventriculography

- ^{99}mTc-tagged to red blood cells
- non-invasive method of assessing ventricular function and intracardiac hemodynamics (i.e. ejection fraction, presence of shunts, ventricular volume, and regional wall motion)
- cardiac MUGA scan sums multiple cardiac cycles, usually at least 200 beats
- indications: most commonly to monitor potential cardiac toxicity with chemotherapy or herceptin, as a gold standard of ejection fraction in defibrillator workup

Abdomen and Genitourinary System

HIDA Scan (Cholescintigraphy)

- IV injection of ^{99}mTc-disofenin (DISIDA) or ^{99}mTc-mebrofenin which is bound to protein, taken up by hepatocytes, and excreted into the biliary system
- indicated for patients who are suspected of having an obstruction in the biliary tract, to assess for bile leaks postoperatively, and for biliary dyskinesia
- indicated in workup of cholecystitis when abdominal U/S result is equivocal:
  - acute cholecystitis: no visualization of gallbladder at 4 h or 1 h after administration of morphine
  - chronic cholecystitis: no visualization of gallbladder at 1 h but seen at 4 h or after morphine administration
- DDx of obstructed cystic duct: acute/chronic cholecystitis, decreased hepatobiliary function (commonly due to alcoholism), bile duct obstruction, parenteral nutrition, fasting <4 h or >24 h

RBC Scan

- IV injection of radiotracer with sequential images of the abdomen (^{99} mTc RBCs)
- GI bleed evaluation
  - if bleeding acutely at <0.5 mL/min, the focus of activity in the images generally indicates the site of the acute bleed
  - if bleeding acutely at >0.5 mL/min, use angiography (more specific, better for localizing, both diagnostic and therapeutic)
- liver lesion evaluation
  - hemangioma has characteristic appearance: cold early (limited blood flow to lesion), fills in later (accumulation of tagged cells greater than surrounding liver parenchyma)

Urea Breath Test

- indication: diagnosis of gastric *H. pylori* infection
- patient administered ^{14}C-labelled urea orally, urea metabolized by *H. pylori* to ammonia and $^{14}CO_2$, ^{14}C-labelled CO_2 is measured via plastic filament detectors or liquid scintillation

Functional Renal Imaging
- evaluation of renal function and anatomy using ^{99}mTc DTPA (static imaging) or ^{99}mTc MAG3 (dynamic imaging)
- frequently used to provide index of relative function between two kidneys
- in adults, used to assess for UPJ obstruction, renal transplants, or as a nuclear glomerular filtration rate study in patients wanting to donate kidneys
- in children, used to assess for pyelonephritis and reflux

Interventional Radiology

Vascular Procedures

Angiography
- injection of contrast material through a catheter placed directly into an artery or vein to delineate vascular anatomy
- can be used in the operating room to provide fluoroscopic guidance for exposure of diseased vessel
- indications: diagnosis of primary occlusive or stenotic vascular disease, aneurysms; coronary, carotid and cerebral vascular disease; PE, trauma, bleeding (GI, hemoptysis, hematuria), vascular malformations, as part of endovascular procedures (endovascular aneurysm repair, thrombolysis, stenting, and angioplasties)
- complications (<5% of patients): puncture site hematoma, pseudoaneurysm, dissection, thrombosis, infection, AV fistula, embolic occlusion of a distal vessel
- due to improved technology, non-invasive evaluation of vascular structures is being performed more frequently (colour Doppler U/S, CTA, and MRA)
- see *Neuroradiology*, MI19

Percutaneous Transluminal Angioplasty and Stents
- introduction and inflation of a balloon into a stenosed or occluded vessel to restore distal blood supply
- common alternative to surgical bypass grafting with 5 yr patency rates similar to surgery, depending on site
- renal, iliac, femoral, mesenteric, subclavian, coronary, and carotid artery stenoses are amenable to treatment
- vascular stents may help improve long-term results by keeping the vessel wall patent after angioplasty; also used for angioplasty failure or complications
- stent grafts (metal mesh covered with durable fabric) may provide an alternative treatment option for aneurysms and AV fistulas
- complications: similar to angiography, but also includes vessel rupture

Thrombolytic Therapy
- may be systemic (IV) or catheter directed
- infusion of a fibrinolytic agent (urokinase, streptokinase, TNK, tPA – used most commonly) via a catheter inserted directly into a thrombus
- can restore blood flow in a vessel obstructed with a thrombus or embolus
- indications: treatment of ischemic limb (most common indication), early treatment of MI or stroke to reduce organ damage, treatment of deep venous thrombosis (DVT) or PE
- complications: bleeding, stroke, distal embolus, reperfusion injury in delayed intervention with myoglobinuria, and renal failure if advanced ischemia present

Embolization
- injection of occluding material into vessels
- permanent agents: amplatzer plugs, coils, glue, and onyx
- temporary: gel foam, autologous blood clots
- indications: management of hemorrhage (epistaxis, trauma, GI bleed, GU bleed), treatment of arteriovenous malformation, preoperative treatment of vascular tumours (bone metastases, renal cell carcinoma), ovarian vein embolization for chronic pelvic pain (pelvic venous disease), varicocele embolization for infertility, symptomatic uterine fibroids
- complications: post-embolization syndrome (pain, fever, leukocytosis), unintentional embolization of a non-target organ with resultant ischemia

Inferior Vena Cava Filter
- insertion of temporary or permanent metallic "umbrellas" to mechanically trap DVT emboli to prevent subsequent PE
- inserted via femoral vein, jugular vein, or basilic vein
- usually placed infrarenally to avoid renal vein thrombosis
- indications: contraindication to anticoagulation, failure of adequate anticoagulation (e.g. recurrent PE despite therapeutic anticoagulant levels), complication of anticoagulation therapy necessitating termination of anticoagulation (e.g. life-threatening hemorrhage)

Thrombolytic Therapy for Pulmonary Embolism
Cochrane DB Syst Rev 2015;9:CD004437
Purpose: To assess the effects of thrombolytic therapy in patients with acute pulmonary embolism (PE).
Methods: Systematic review of RCTs evaluating thrombolytic therapy followed by heparin vs. heparin alone, heparin plus placebo or surgical intervention in patients with acute PE. Main outcomes of interest were death, recurrence of PE, and major and minor hemorrhagic events.
Results: Twenty-one trials (n=2401) were included. Thrombolytics plus heparin was associated with a reduction in odds of death relative to heparin alone or heparin plus placebo (OR 0.58; 95% CI, 0.38 to 0.88, low-certainty) and recurrence of PE (OR 0.54; 95% CI, 0.32 to 0.91, low-certainty). Incidence of major hemorrhagic events was higher in the thrombolytic group as compared to control (OR 2.84; 95% CI, 1.92 to 4.20), as well as minor hemorrhagic events (OR 2.97; 95% CI, 1.66 to 5.30). Length of hospital stay was reduced in the thrombolytics group as compared to controls (mean difference (MD) −1.40 days; 95% CI, −2.69 to −0.11).
Conclusion: Low-certainty evidence suggests thrombolytics reduce death following acute PE compared with heparin and may be helpful in reducing PE recurrence, but may cause more hemorrhagic events.

Central Venous Access
- variety of devices available (PICC, external tunneled catheter (Hickman or dialysis catheters), subcutaneous port (Portacath®))
- indications: chemotherapy, TPN, long-term antibiotics, administration of fluids and blood products, blood sampling
- complications: venous thrombosis, central venous stenosis, infection including sepsis, and pneumothorax

Breast Imaging

Modalities

Mammography

Description
- x-ray imaging of the breasts for screening in asymptomatic patients, or diagnosis of clinically-detected or screening-detected abnormalities (see General and Thoracic Surgery, GS67)
- routine evaluation involves two standard views: cranio-caudal and medial-lateral-oblique

Indications
- screening (for guidelines, see Family Medicine, FM4)
  - guidelines may vary by region
- surveillance
  - follow-up of women with previous breast cancer
- diagnostic: includes mammography with special views and/or U/S
  - workup of an abnormality that may be suggestive of breast cancer including a lump or thickening, localized nodularity, dimpling or contour deformity, a persistent focal area of pain, overlying skin changes, and spontaneous serous or sanguinous nipple discharge from a single duct
  - women with abnormal screening mammograms
  - suspected complications of breast implants

Table 19. Breast Imaging Reporting and Data System (BI-RADS®) Mammography Categories

Assessment Categories	Imaging Findings	Likelihood of Malignancy (%)	Follow-Up Recommendations
BI-RADS 0	Incomplete	N/A	Additional imaging Comparison to prior films
BI-RADS 1	Negative	~0	Routine screening
BI-RADS 2	Benign	~0	Routine screening
BI-RADS 3	Probably benign Likelihood of malignancy is <2%	0-2	Unilateral mammogram at 6 mo
BI-RADS 4	Suspicious abnormality	3-94	Biopsy
BI-RADS 4A	Low suspicion for malignancy	3-10	Biopsy
BI-RADS 4B	Low suspicion for malignancy	11-50	Biopsy
BI-RADS 4C	Low suspicion for malignancy	51-94	Biopsy
BI-RADS 5	Highly suspicious of malignancy	≥95	Biopsy
BI-RADS 6	Malignancy confirmed by biopsy	100	Definitive therapy

Breast Ultrasound

Indications
- characterization of palpable abnormalities
  - U/S is 1st line in <30 yr – denser breast tissue makes mammograms less sensitive in young females
  - first line in lactating and pregnant women
  - >30 yr need mammogram first
- further characterization of mammographic findings
- guidance for interventional procedures

Breast MRI

Description
- contrast-enhanced MRI of the breasts
- sensitive for detecting invasive breast cancer (95-100%) but specificity variable (37-97%)
- for diagnosis, used only after mammography and U/S investigation
- use as a screening modality is limited to high-risk patients, in conjunction with mammography

Indications
- "problem-solving" of indeterminate findings following complete mammographic and U/S workup
- evaluation of occult primary in patients presenting with axillary metastases
- evaluation of patients with suspected silicone implant rupture and problems associated with breast implants
- evaluation of previously diagnosed breast cancer: positive margins, recurrence, response to chemotherapy
- high-risk screening
  - known BRCA1 or BRCA2 mutation, or other gene predisposing to breast cancer, or untested first-degree relative of a carrier of such a gene mutation
  - family history consistent with a hereditary breast cancer syndrome and/or estimated personal lifetime cancer risk >25%
  - high-risk marker on prior biopsy (atypical ductal hyperplasia, atypical lobular hyperplasia, lobular carcinoma in situ)
  - radiation therapy to chest (before age 30)

Breast Interventional Procedures

Description
- includes core needle biopsy, stereotactic biopsy, MRI-guided biopsy, abscess drainage, and cyst aspiration

Indications
- cystic mass: complex cyst, symptomatic, suspected abscess
- solid mass: confirm diagnosis of a lesion suspicious for malignancy (BI-RADS® Category 4 or 5)
- suspicious calcifications: confirm diagnosis of a lesion suspicious for malignancy (BI-RADS® Category 4 or 5) – stereotactic biopsy
- initial percutaneous biopsy procedure that was insufficient or discordant with imaging
- presurgical wire localization of a lesion

Breast Findings

Breast Masses
- definition: a space-occupying lesion seen in two different projections; if seen in only a single projection it should be called an "asymmetry" until its three-dimensionality is confirmed

Table 20. Mammographic Features of Benign and Malignant Breast Masses

	Benign	Malignant
Shape	Oval, round, lobular	Irregular
Margin	Circumscribed, well-defined	Indistinct, microlobulated, spiculated
Density	Radiolucent (oil cyst, lipoma, fibrolipoma, galactocele, hamartoma)	Radiodense
Calcifications (± mass)	Popcorn (hyalinizing fibroadenoma), lucent centred (oil cyst/fat necrosis), layering (milk of calcium), vascular, round, scattered	Pleomorphic (vary in size and shape), amorphous (indistinct), fine linear, coarse heterogeneous, regional, segmental, clustered

Other Findings
- tubular density/dilated duct: branching tubular structures usually represent enlarged ducts (milk ducts); if they are clearly identified as such, these densities are of little concern
- intramammary lymph node: typical lymph nodes are well-circumscribed, reniform and often have a fatty notch and centre; usually <1 cm, and usually seen in the outer, often upper part of the breast; when these characteristics (particularly fatty centre or notch) are well seen, the lesion is almost always benign and insignificant
- focal asymmetry: area of breast density with similar shape on two views, but completely lacking borders and conspicuity of a true mass; must be carefully evaluated with focal compression to exclude findings of a true mass or architectural distortion
- if focal compression shows mass-like character – or if the area can be palpated – biopsy generally recommended

Landmark Radiology Trials

Trial Name	Reference	Clinical Trial Details
VASCULAR PROCEDURES		
PREPIC	NEJM 1998;338:409-416	**Purpose**: To study the efficacy and safety of vena caval filters in preventing the formation of PEs in patients with proximal DVT. **Methods**: RCT consisting of 400 patients with proximal DVT who were randomized to receive heparin in conjunction with either a caval filter or no filter. **Results**: 2 patients within the treatment group and 9 patients within the control group had experienced a PE within 12 d. 37 patients within the treatment group and 21 patients within the control group experienced recurrent DVT within 2 yr. **Conclusion**: Benefits of vena caval filters were counterbalanced by their risks. Filters resulted in no significant difference in mortality or other outcomes and although they prevented PE within 12 d, they increased the risk of recurrent DVT within 2 yr.
EVAR	NEJM 2010;362:1863-1871	**Purpose**: To understand the long term implications of endovascular repair of abdominal aortic aneurysms. **Methods**: RCT consisting of 1252 patients with abdominal aortic aneurysms were randomized to undergo an endovascular or open repair. The outcomes of interest included mortality, graft-related complications, and re-interventions. **Results**: The 30 d postoperative mortality was lower in the endovascular repair group (1.8% vs. 4.3%). However, due to graft ruptures, the mortality rates equilibrated over time. The rates of graft-related complications and re-interventions were higher in the group that underwent endovascular repair. **Conclusion**: Mortality at 30 d post-operation was significantly lower for endovascular repair compared to open repair. At the end of follow-up (5-10 yr), there was no significant difference in mortality and rates of complication were higher in the endovascular treatment group.
NCT03702413	NEJM 2022; 386:1303-1313	**Title**: Endovascular Therapy for Acute Stroke with a Large Ischemic Region **Purpose**: Endovascular therapy is often avoided for patients with large cerebrovascular infarctions, however the benefits of endovascular therapy in combination with stroke medical care has not been studied. **Methods**: RCT consisting of 203 patients with occlusion of large cerebral vessels and an Alberta Stroke Program Early Computed Tomographic Score between 3-5. Patients were randomized to receive endovascular therapy in conjunction with medical care or medical care alone. The primary outcome is a modified Rankin score between 0 and 3, 90-d post-treatment. **Results**: A larger proportion of patients treated with endovascular therapy in conjunction with medical care achieved a modified Rankin score between 0 and 3 (31%) compared to medical care alone (12.7%). **Conclusion**: In patients with large cerebrovascular occlusions, treatment with endovascular therapy in conjunction with medical care resulted in improved functional outcomes when compared to treatment with medical care alone.
AMACING	Lancet 2017;389:1312-1322	**Title**: Prophylactic Hydration To Protect Renal Function From Intravascular Iodinated Contrast Material In Patients At High Risk Of Contrast-Induced Nephropathy **Purpose**: To determine the effectiveness of prophylactic hydration in protecting renal function in high risk individuals. **Methods**: RCT of 660 patients at high risk of contrast-induced nephropathy (eGFR 30-59) who were receiving iodinated contrast for an elective procedure. Patients were randomized to receive IV 0.9% NaCl vs. no treatment. Primary outcome was contrast-induced nephropathy (over 35% or 44µmol increase in serum creatinine from baseline in 2-6 days). **Results**: Contrast-induced nephropathy was observed in 2.7% of patients receiving prophylactic hydration and in 2.6% of non-hydrated patients. **Conclusion**: No prophylactic hydration is non-inferior to IV hydration in the prevention of contrast-induced nephropathy in high-risk patients.
RENOVATE-COMPLEX-PCI	NEJM 2023;388:1668-1679	**Title**: Intravascular Imaging-Guided or Angiography-Guided Complex PCI **Purpose**: To assess the clinical outcomes in patients receiving intravascular imaging-guided percutaneous coronary intervention (PCI) as compared to angiography-guided PCI in patients with complex coronary-artery lesions. **Methods**: RCT of 1639 patients with complex coronary-artery lesions who were randomized to undergo either intravascular imaging-guided PCI or angiography-guided PCI. Primary endpoint was death from cardiac causes, target-vessel-related MI, or target-vessel revascularization. **Results**: Cardiac-related death occurred in 1.7% and 3.8% of patients in the intravascular imaging-guided PCI and angiography-guided PCI groups, respectively. Target-vessel-related MI occurred in 3.7% and 5.6% of patients, respectively, and target-vessel revascularization occurred in 3.4% and 5.5% of patients, respectively. **Conclusion**: As compared to angiography-guided PCI, intravascular imaging-guided PCI is associated with lower risk of death from cardiac causes, target-vessel-related MI, or target-vessel revascularization.
DISCHARGE	NEJM 2022;386:1591-1602	**Title**: CT or Invasive Coronary Angiography in Stable Chest Pain **Purpose**: To assess the rates of major adverse cardiovascular events between CT and invasive coronary angiography (ICA) in the diagnosis of obstructive CAD. **Methods**: RCT of 3561 patients with stable chest pain and an indeterminate pretest probability of obstructive CAD who were randomized to receive CT or ICA as initial diagnostic testing. Primary outcome was a major adverse CV event in a 3.5 yr period. Secondary outcomes were complications of the procedure and angina pectoris. **Results**: Major adverse CV events were observed in 2.1% and 3.0% of patients in CT and ICA groups, respectively (HR 0.7; 95% CI, 0.46-1.07; P=0.10). Major procedure-related complications were observed in 0.5% and 1.9% of patients in CT and ICA groups, respectively (HR 0.26; 95% CI, 0.13-0.55). Angina was reported in 8.8% and 7.5% of patients, respectively (OR 1.17; 95% CI, 0.92-1.48). **Conclusion**: The risk of major adverse cardiovascular events was comparable between CT and ICA groups. CT was associated with a lower risk of major procedure-related complications.
NUCLEAR MEDICINE		
ESTIMABL2	NEJM 2022; 386:923-932	**Title**: Thyroidectomy without Radioiodine in Patients with Low-Risk Thyroid Cancer **Purpose**: To assess the clinical benefit of postoperative radioiodine, after thyroidectomy in low-risk thyroid cancer. **Methods**: RCT consisting of 730 patients with low-risk differentiated thyroid cancer undergoing thyroidectomy. Patients were randomized to either receive or not receive radioiodine. The outcomes of interest were the presence of abnormal radioiodine foci, abnormal neck ultrasound, or presence of increased thyroglobulin/thyroglobulin antibodies. **Results**: There was no significant difference in postoperative abnormalities between patients that received (4.1%) and did not receive postoperative radioiodine (4.4%). **Conclusion**: The use of radioiodine is negligible in the prevention of post-thyroidectomy abnormalities.

ACEI	angiotensin converting enzyme inhibitor	DIC	disseminated intravascular coagulation	NS	normal saline
ACR	urine albumin to creatinine ratio	DKA	diabetic ketoacidosis	p-ANCA	perinuclear anti-neutrophil cytoplasmic antibody
ADH	antidiuretic hormone	DM	diabetes mellitus	PCT	proximal convoluted tubule
AG	anion gap	ECF	extracellular fluid	PJP	*Pneumocystis jiroveci* pneumonia
AIN	acute interstitial nephritis	eGFR	estimated glomerular filtration rate	PKD	polycystic kidney disease
AKI	acute kidney injury	ESR	erythrocyte sedimentation rate	PTH	parathyroid hormone
ANA	antinuclear antibody	ESRD	end-stage renal disease	R&M	routine and microscopy
ARB	angiotensin receptor blocker	FENa	fractional excretion of sodium	RAAS	renin-angiotensin-aldosterone system
ASA	acetylsalicylic acid	FF	filtration fraction	RBF	renal blood flow
ASOT	anti streptolysin-O titer	FSGS	focal segmental glomerulosclerosis	RCC	renal cell carcinoma
ATN	acute tubular necrosis	GBM	glomerular basement membrane	RPF	renal plasma flow
AV	atrioventricular	GFR	glomerular filtration rate	RPGN	rapidly progressive glomerulonephritis
AVM	arteriovenous malformation	GN	glomerulonephritis	RRT	renal replacement therapy
c-ANCA	cytoplasmic antineutrophil cytoplasmic antibody	HAART	highly active antiretroviral therapy	RTA	renal tubular acidosis
C&S	culture and sensitivity	HBV	hepatitis B virus	SIADH	syndrome of inappropriate antidiuretic hormone
CHF	congestive heart failure	HCTZ	hydrochlorothiazide	SLE	systemic lupus erythematosus
CKD	chronic kidney disease	HCV	hepatitis C virus	SLED	sustained low efficiency dialysis
Cr	creatinine	HPF	high power field	TBW	total body water
CrCl	creatinine clearance	HSP	Henoch-Schönlein purpura	TIN	tubulointerstitial nephritis
CV	cardiovascular	HTN	hypertension	TTP	thrombotic thrombocytopenic purpura
CVVHD	continuous veno-venous hemodialysis	HUS	hemolytic uremic syndrome	UAG	urine anion gap
D5W	5% dextrose in water	IVP	intravenous pyelogram	UTI	urinary tract infection
DCT	distal convoluted tubule	LOC	level of consciousness		
DDAVP	1-desamino-8-d-arginine vasopressin	MDRD	modification of diet in renal disease		
DI	diabetes insipidus				

Basic Anatomy Review

Embryology of the Kidney

- originates from urogenital ridge of the intermediate mesoderm
- pronephros develops at the end of wk 3, then degenerates along with adjacent pronephric duct, disappearing completely by end of wk 4
- mesonephros develops caudal to the pronephros in wk 4, degenerates, and the remnants form the mesonephric (Wolffian) duct of the male reproductive system
- metanephros develops caudal to the mesonephros in wk 5 from the metanephric blastema and the ureteric bud of the mesonephric duct, forming the definitive kidney
  - excretory system: metanephric blastema → nephrons (i.e. glomeruli, Bowman's capsule, PCT, loop of Henle, DCT)
  - collecting system: ureteric bud → collecting ducts, calyces, renal pelvis, ureters
  - kidneys ascend from the pelvis into the retroperitoneum, gaining a blood supply from the abdominal aorta to form the renal arteries

Renal Structure and Function

The Nephron

- basic structural and functional unit of the kidney, approximately 1 million per kidney
- 2 main components: glomerulus and attached renal tubule
- direction of blood flow: afferent arteriole → glomerular capillaries → efferent arteriole → vasa recta (the capillaries surrounding the tubules) → renal venules

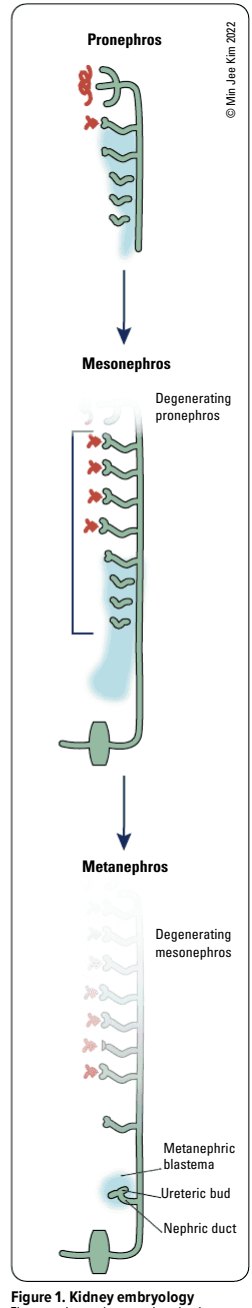

Figure 1. Kidney embryology
The pronephros and mesonephros develop then degenerate in succession. Ultimately, the definitive kidney develops from the metanephric blastema and ureteric bud of the mesonephric duct

Table 1. Major Kidney Functions

Function	Mechanism	Affected Elements
1. Waste Excretion	Glomerular filtration	Excretion of nitrogenous products of protein metabolism (urea, Cr)
	Tubular secretion	Excretion of organic acids (urate) and organic bases (Cr)
	Tubular catabolism	Breakdown and excretion of drugs (antibiotics, diuretics) and peptide hormones (most pituitary hormones, insulin, glucagon)
2. Electrolyte Balance and Osmoregulation	Tubular NaCl and water reabsorption	Controls volume status and osmolar balance
	Tubular K^+ secretion	Controls potassium concentration
	Tubular H^+ secretion	Acid-base balance
	HCO_3^- synthesis and reabsorption	Acid-base balance
	Tubular Ca^{2+}, Mg^{2+}, PO_4^{3-} transport	Alters Ca^{2+}, Mg^{2+}, PO_4^{3-} homeostasis
	Osmolyte synthesis	Increase osmolality of medullary cytoplasm to match medullary concentration gradient
3. Hormonal Synthesis	Erythropoietin production (cortex)	Red blood cell production
	Vitamin D activation: 25(OH)Vitamin D converted to 1,25(OH)2Vitamin D (proximal tubule)	Calcium homeostasis
	Renin production (juxtaglomerular apparatus)	Alters vascular resistance and aldosterone secretion
4. Blood Pressure Regulation	Na+ excretion	Alters ECF volume
	Renin production	Alters vascular resistance
5. Glucose Homeostasis	Gluconeogenesis (from lactate, pyruvate, and amino acids)	Glucose supply maintained in prolonged starvation
	Clearance and degradation of circulating insulin	Maintains glucose homeostasis

The Glomerulus

- site where blood constituents are filtered through to the kidney tubules for excretion or reabsorption
- filtration occurs across the glomerular filtration barrier (endothelium, GBM, podocytes) into Bowman's space
- there is a filtration barrier to large negatively charged molecules, e.g. albumin
- consists of following cell types:
  1. mesangial cells
     - structural function: support glomerular capillaries; can alter GFR through contractile activity
     - secretory function: matrix components, pro- and anti-inflammatory cytokines, and chemokines
     - secretions are responsible for minimizing the accumulation of macromolecules in the mesangial space and GBM
  2. capillary endothelial cells
     - part of the glomerular filtration barrier; help form the plasma filtration apparatus due to their fenestrated nature and glycocalyx; contribute to the production of the GBM
     - interface with blood – target for antibodies and contact site for neutrophils and lymphocytes
  3. visceral cells (podocytes)
     - part of the glomerular filtration barrier; helps form the plasma filtration apparatus due to their interdigitated foot process forming slit diaphragms; contribute to the production of extracellular matrix proteins (collagen and laminin) making up the GBM
  4. parietal cells
     - lines the interior of Bowman's capsule and contains a podocyte progenitor population
  5. juxtaglomerular cells
     - smooth muscle cells in the lining of afferent arteriole, adjacent to the macula densa cells in the distal tubule; produce, store, and secrete renin

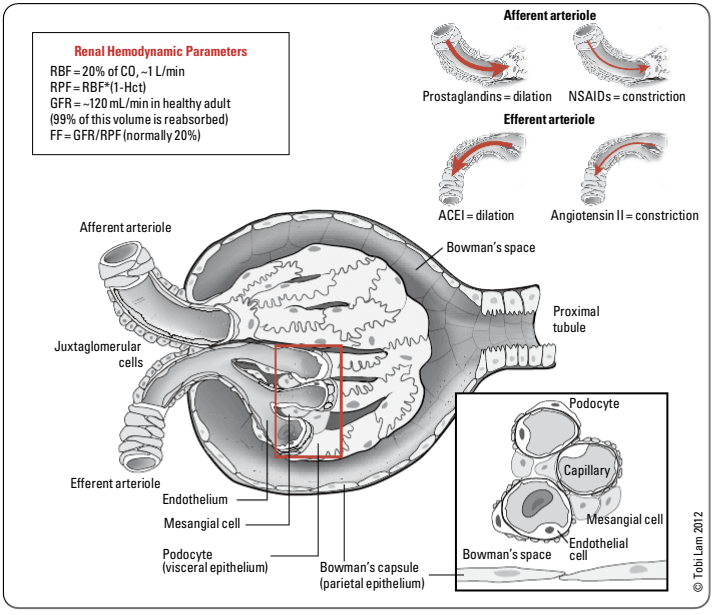

Figure 2. The glomerulus

The Renal Tubules

- reabsorption and secretion occur between the renal tubules and vasa recta, forming urine for excretion
- each segment of the tubule selectively transports various solutes and water, and is targeted by specific diuretics

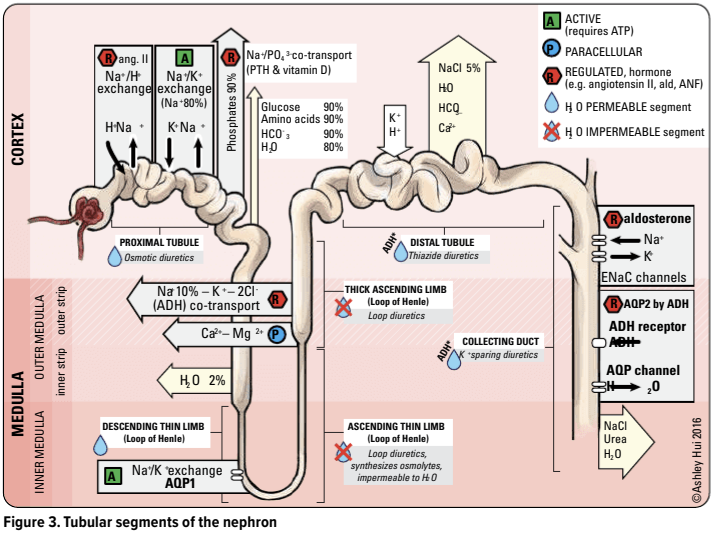

Figure 3. Tubular segments of the nephron

Renal Hemodynamics

- GFR
  - GFR is the rate of fluid transfer between glomerular capillaries and Bowman's space, expressed as the sum of the filtration across all nephrons
  - average GFR of 180 L/d or 125 mL/min/1.73 m ^{2}, of which 99% of the filtrate is reabsorbed
  - normal urine output is 0.5-2.0 mL/kg/h in adults
  - GFR is highest in early adulthood, and decreases thereafter starting around age 40
- renal autoregulation maintains constant GFR over mean arterial pressures of 70-180 mmHg
- 2 mechanisms of autoregulation to maintain GFR homeostasis:
  - myogenic mechanism: release of vasoactive factors in response to changes in perfusion pressure (e.g. low GFR → decreased perfusion pressure → release of prostaglandin → afferent arteriolar dilation → increased GFR)
  - tubuloglomerular feedback: changes in Na^+ delivery to macula densa lead to changes in afferent arteriolar tone (e.g. high GFR → increased Na^+ delivery → afferent constriction → decreased GFR)
- filtration fraction
  - percentage of RPF filtered across the glomeruli
  - expressed as a ratio: FF = GFR/RPF; normal = 0.2 or 20%
  - angiotensin II constricts renal efferent arterioles which increases FF, thereby maintaining GFR
- renin is released from juxtaglomerular apparatus in response to low Na^+ delivery to the macula densa, which is an indicator of decreased RPF
  - renin is an important enzyme in the RAAS pathway, that converts angiotensinogen to angiotensin I

Glomerular Filtration Rate	
GFR	Kf (ΔP – ΔΠ)
Kf	ultrafiltration coefficient
ΔP	hydrostatic pressure difference between glomerular capillaries and Bowman's space
ΔΠ	osmotic pressure difference between glomerular capillaries and Bowman's space
ΔP – ΔΠ	net outward pressure

Considerable variation in GFR is observed based on age, biological sex, ethnicity, and BMI

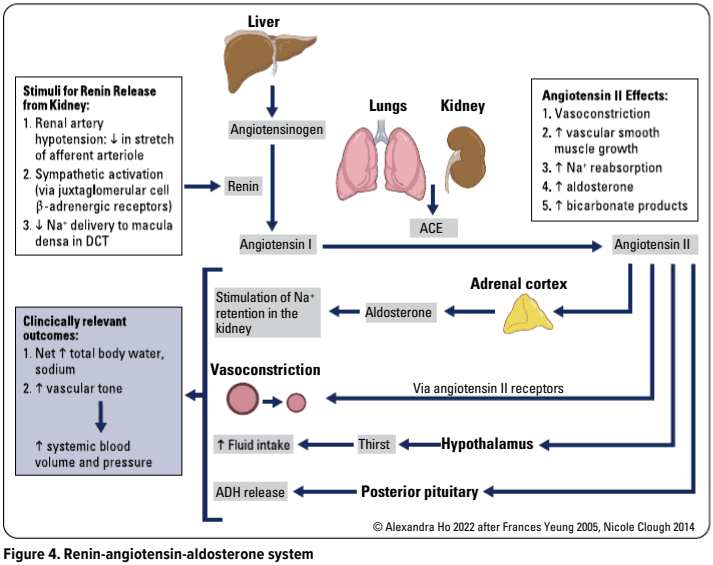

Figure 4. Renin-angiotensin-aldosterone system

Assessment of Renal Function

Measurement of Renal Function

- most renal functions decline in parallel with a decrease in GFR
- inulin clearance and iothalamate radiotracer are the gold standard for measuring GFR, but very rarely used clinically
- clinically, GFR is estimated using serum creatinine concentration, [Cr], known as eGFR
  - Cr filtered ≈ Cr excreted (at steady state)
  - Cr reasonably estimates GFR as it is freely filtered at the glomerulus with little tubular reabsorption

Crfiltered = Crexcreted
[Cr]plasma x GFR = [Cr]urine x urine flow rate (mL/min)
GFR = $\frac{[Cr]urine \times urine\ flow\ rate}{[Cr]plasma}$

- however, Cr is a metabolite of creatine phosphate, and therefore increased muscle mass increases Cr production. Thus, one needs to consider body mass, ethnicity, age, and biological sex when determining eGFR
- there is also 10% to >50% tubular secretion of Cr, depending on renal function

- newly discovered biomarkers such as Cystatin C, which are not affected by muscle mass, may provide more accurate eGFR values

Ways to Estimate GFR Using Serum Creatinine Concentration

1. estimate GFR using CKD-EPI equation
   - the best current and most accurate equation
   - calculated using serum Cr, age, biological sex, and race
   - equation performance improves at low GFR
2. measure CrCl – 24 h urine collection
   - calculation provides reasonable estimate of GFR
   - GFR/d = (urine [Cr] x 24 h urine volume)/(plasma [Cr])
   - must use same units for urine [Cr] and plasma [Cr]
3. estimate GFR with new Cr and cystatin C-based equations
   - serum Cr and cystatin C values used with age and sex to estimate GFR (excludes the race variable)
   - more accurate than CKD-EPI with race omitted

Limitations of Using Serum Cr Measurements

1. must be in steady state
   - constant GFR and rate of production of Cr from muscles
   - sudden kidney injury (e.g. AKI) may reduce GFR substantially, however, serum Cr will not immediately reflect sudden reduction in GFR until new Cr steady state is reached
2. GFR must fall substantially before plasma [Cr] rises above normal laboratory range due to compensatory factors
   - with progressive renal failure, remaining nephrons compensate with vascular autoregulation and hyperfiltration
   - GFR is relatively preserved despite significant structural damage
3. plasma [Cr] is influenced by the rate of Cr production
   - lower production with smaller muscle mass (e.g. female, elderly, low weight)
     - e.g. consider plasma [Cr] of 100 µmol/L in both of these patients
       - 20 yr lean man who weighs 100 kg, GFR = 144 mL/min
       - 80 yr woman who weighs 50 kg, GFR = 30.6 mL/min
   - clinical correlation: GFR decreases with age but would not be reflected as a rise in serum Cr due to the age-associated decline in muscle mass
4. tubular secretion of Cr increases as GFR decreases
   - serum Cr and CrCl overestimate low GFR
   - certain drugs (cimetidine, trimethoprim) interfere with Cr secretion
5. errors in Cr measurement (in older lab evaluation methods)
   - very high bilirubin level causes [Cr] to be falsely low
   - acetoacetate (a ketone body) and certain drugs (cefoxitin) create falsely high [Cr]

Measurement of Urea Concentration

- urea is the major end-product of protein metabolism
- urea production reflects dietary intake of protein and catabolic rate; increased protein intake or catabolism (sepsis, trauma, GI bleed) causes increase in urea level
- ECF volume depletion causes a rise in urea independent of GFR or plasma [Cr]
- in addition to filtration, a significant amount of urea is reabsorbed along the tubule
- reabsorption is increased in hypernatremic states
- typical ratio of urea to [Cr] in serum is 1:12 in SI units (using mmol/L for urea and µmol/L for Cr)

Urinalysis

- use dipstick in freshly voided urine specimen to assess the following:

1. Specific Gravity

- ratio of the mass of equal volumes of urine/H_2O
- range is 1.001-1.030
- values <1.010 reflect dilute urine, values >1.020 reflect concentrated urine
- value usually 1.010 (isosthenuria: same specific gravity as plasma) in CKD

2. pH

- urine pH is normally between 4.5-8.0; if persistently alkaline, consider
  - RTA (types I-IV)
  - UTI with urease-producing bacteria (e.g. *Proteus*)

At steady state [Cr]serum α 1/CrCl

CKD-EPI Equation
eGFR (mL/min/1.73 m²) = 141 x min(SCr/κ, 1)α x max(SCr/κ, 1)$^{-1.209}$ x 0.993age
x (1.018 if female) x (1.159 for Black individuals)
[SCr] measured in mg/dL; 1 mg/dL [Cr] = 88.4 µmol/L
κ = 0.7 for females and 0.9 for males
α = -0.329 for females and -0.411 for males
min/max indicates the minimum/maximum of SCr/κ or 1

Cystatin C
Cystatin C is a renal biomarker shown to be potentially superior to serum Cr in determining eGFR and detecting impaired filtration rate. However, its clinical use remains limited pending increased adoption and testing availability

Clinical Settings in which Urea Level is Affected Independent of Renal Function

Disproportionately High Urea

Volume depletion (prerenal azotemia)
GI hemorrhage
High protein diet
Sepsis
Catabolic state with tissue breakdown
Corticosteroid or cytotoxic agents

Disproportionately Low Urea

Low protein diet
Liver disease

Estimating Urine Osmolality
Last 2 digits of the specific gravity x 30 = urine osmolality approximately
(e.g. specific gravity of 1.020 = 600 mOsm)

3. Glucose
- freely filtered at glomerulus and reabsorbed in proximal tubule
- causes of glycosuria include:
  1. hyperglycemia >9-11.1 mmol/L leads to filtration that exceeds tubular resorption capacity
  2. increased GFR (e.g. pregnancy: the proximal convoluted tubule is unable to reabsorb the glucose and amino acids)
  3. proximal tubule dysfunction (e.g. Fanconi's syndrome)
  4. sodium-glucose cotransporter 2 (SGLT2) inhibitors (i.e. -flozin drugs) which are prescribed for DM2; lower the threshold for glucosuria by preventing glucose reabsorption from the filtrate

24 h Urine Collection
Discard first morning specimen
Collect all subsequent urine for the next 24 h
Refrigerate between voids
Collect second morning specimen

4. Protein
- dipstick only detects albumin; other proteins (e.g. Bence-Jones (monoclonal light chains), immunoglobulins, Tamm-Horsfall) may be missed
- microalbuminuria (morning ACR of 2.0-20 mg/mmol) is not detected by standard dipstick; greater than these ranges would be macroalbuminuria
- gold standard: 24 h timed urine collection for total protein
- urine PCR and ACR can estimate proteinuria and albuminuria respectively. To approximate 24 h urine albumin excretion, multiply ACR by 10 for women and by 15 for men

Positive dipstick for leukocyte esterase and nitrites is highly specific for diagnosing a UTI

5. Leukocyte Esterase
- enzyme found in WBC and detected by dipstick
- presence of WBCs indicates infection (e.g. UTI) or inflammation along the urinary tract including prostate, bladder, ureter, pelvis, and renal interstitium (e.g. AIN)

Nitrite Negative Bacteria
Enterococci
Staphylococci

6. Nitrites
- endogenous nitrates in urine are converted to nitrites by some bacteria (most commonly *E. coli*)
- high specificity but low sensitivity for UTI

Nitrite Positive Bacteria (usually Gram negative bacteria)
Enterobacteriaceae (e.g. *E. coli*)

7. Ketones
- positive in alcoholic/diabetic ketoacidosis, prolonged starvation, fasting

8. Hemoglobin
- positive in hemoglobinuria (hemolysis), myoglobinuria (rhabdomyolysis), and true hematuria (RBCs seen on microscopy)

Urine Microscopy

Table 2. Comparison of Urinary Sediment Findings

	Active Sediment = Suggestive of Parenchymal Kidney Disease	Bland Sediment = Less Likely Parenchymal Kidney Disease
Any one or more of the following seen on microscopy	Red cell casts	Only hyaline casts
	White cell casts	Small quantities of crystals
	Muddy-brown granular or epithelial cell casts	Small amount of bacteria
	>2 red cells per HPF	<2 red cells per HPF
	>4 white cells per HPF	<4 white cells per HPF

1. CELLS

Erythrocytes
- hematuria ≥5 RBCs per HPF
- dysmorphic RBCs and/or RBC casts suggest glomerular or nephronal in origin (e.g. proliferative GN)
- isomorphic RBCs or no casts suggest extraglomerular bleeding (e.g. bladder cancer)

Leukocytes
- pyuria = greater than upper limit of normal: >4 WBCs per HPF
- indicates inflammation or infection
- if persistent sterile pyuria present (i.e. negative culture), consider: chronic urethritis, prostatitis, interstitial nephritis, calculi, allergic cystitis, interstitial cystitis, papillary necrosis, renal tuberculosis, viral infections, *N. gonorrhoeae, C. trachomatis* infection

Eosinophils
- detected using Wright's or Hansel's stain (not affected by urine pH)
- consider AIN, atheroembolic disease

Oval Fat Bodies
- tubular epithelial cells or macrophages laden with lipid droplets
- seen in heavy proteinuria (e.g. nephrotic syndrome)

2. CASTS

- cylindrical structures formed by intratubular precipitation of Tamm-Horsfall mucoprotein; cells may be trapped within the matrix of protein
- casts originate only from the nephron

Table 3. Interpretation of Casts

Casts	Interpretation
Hyaline Casts	Physiologic (concentrated urine, fever, exercise)
Granular Casts	CKD ATN (less specific)
RBC Casts	Glomerular bleeding (proliferative GN, vasculitis)
WBC Casts	Infection (pyelonephritis) Inflammation (interstitial nephritis)
Pigmented Granular Casts (heme granular casts, muddy brown)	ATN Acute proliferative GN
Fatty/Lipid Casts	Nephrotic syndrome (proteinuria >3.5 g/d)

3. CRYSTALS

- uric acid (rosette shaped or needle shaped): consider acidic urine, hyperuricosuria, tumour lysis syndrome
- calcium phosphate: alkaline urine
- calcium oxalate (envelope shaped): consider hyperoxaluria, ethylene glycol poisoning, nephrolithiasis
- sulfur: sulfa-containing antibiotics
- triple phosphate (coffin-lid shaped): consider UTI -Kelbsiella
- acyclovir

Urine Biochemistry

- commonly measure: Na^+, K^+, Cl^-, osmolality, and pH
- 24 h urine collection more reflective of mineral balance
- no "normal" values; electrolyte excretion depends on intake and current physiological state
- results must be interpreted in the context of a patient's current state, for example:
  1. ECF volume depletion: expect low urine [Na^+] (kidneys should be retaining Na^+)
     - urine [Na^+] >20 mmol/L suggests a tubular injury or the action of a diuretic
     - urine [Na^+] <20 mmol/L suggests a prerenal problem
  2. daily urinary potassium excretion rate should be decreased (<20 mmol/d) in hypokalemia
     - if higher than 20 mmol/d, suggests renal contribution to hypokalemia or action of a diuretic
- osmolality is useful to estimate the kidney's concentrating ability
- FE_{Na} refers to the fractional excretion of Na^+ (Na excreted in urine/Na filtered through kidney)
  - FE_{Na} <1% suggests the pathology is prerenal
- urine pH is useful to grossly assess renal acidification
  - low pH (<5.5) in the presence of low serum pH is an appropriate renal response
  - a high pH in this setting might indicate a renal acidification defect (e.g. RTA Type 1)

Fractional Excretion of Sodium

$$FE_{Na} = \frac{[Na^+]_{urine} \times [Cr]_{plasma}}{[Na^+]_{plasma} \times [Cr]_{urine}} \times 100$$

Electrolyte Disorders

Sodium Homeostasis

- hyponatremia and hypernatremia are disorders of water balance
  - hyponatremia usually suggests too much water in the ECF relative to Na^+ content
  - hypernatremia usually suggests too little water in the ECF relative to Na^+ content
- solutes (such as Na^+, K^+, glucose) that cannot freely traverse the plasma membrane contribute to effective osmolality and induce transcellular shifts of water
  - water moves out of cells in response to increased ECF osmolality
  - water moves into cells in response to decreased ECF osmolality
- ECF volume is determined by Na^+ content rather than concentration
  - Na^+ deficiency leads to ECF volume contraction
  - Na^+ excess leads to ECF volume expansion
- clinical signs and symptoms of hyponatremia and hypernatremia are secondary to cells (especially brain cells) shrinking (hypernatremia) or swelling (hyponatremia)

Table 4. Clinical Assessment of ECF Volume* (Total Body Na^+)

Fluid Compartment	Hypovolemic	Hypervolemic
Intravascular		
JVP	Decreased	Increased
Blood pressure	Orthostatic drop	Normal to increased
Auscultation of heart	Tachycardia	S3
Auscultation of lungs	Normal	Inspiratory crackles
Interstitial		
Skin turgor	Decreased	Normal/increased
Edema (dependent)	Absent	Present
Other		
Urine output	Decreased**	Variable
Body weight	Decreased	Increased
Hematocrit, serum protein	Increased	Decreased
Urine sodium	Increased/Decreased***	Decreased
IVC size****	≤2.1 cm	>2.1 cm
IVC collapse on inspiration	>50%	<50%

*Refers to effective circulating volume (ECV), which is the ECF volume perfusing tissues
**If there is a renal abnormality (e.g. osmotic diuresis), the urine output may be increased despite the presence of hypovolemia
***In hypovolemia, urine sodium can be increased due to renal losses, or decreased due to extra-renal losses
****IVC ultrasound during respiration assesses central venous pressure/right atrial pressure; lung ultrasound for B-lines can also be used for assessment of pulmonary congestion

Hyponatremia

Definition

- serum [Na +] <135 mmol/L
- can be associated with hypo-osmolality (most common), iso-osmolality, or hyperosmolality
- consider if it is associated with "appropriate" (hypovolemia) vs. "inappropriate" (euvolemia) ADH secretion
- if appropriate ADH secretion, is it real vs. effective volume loss?

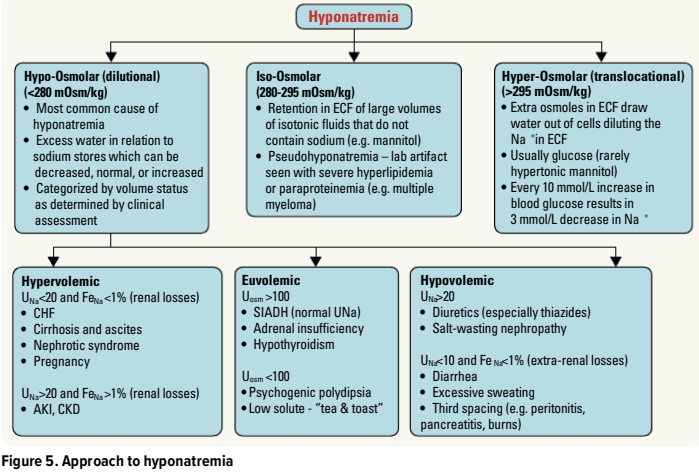

Figure 5. Approach to hyponatremia

If the urine osmolality is unknown, assume the urine is hypo-osmolar/dilute

Hypovolemic hyponatremia -H_2O loss < Sodium loss
Hypervolemic hyponatremia -H_2O gain > Sodium gain
Euvolemic hyponatremia -H_2O gain, neutral sodium balance

Signs and Symptoms

- depend on degree of hyponatremia and, more importantly, velocity of progression from onset
- hyponatremia = swollen cells
- acute hyponatremia (<48 h) more likely to be symptomatic
- chronic hyponatremia (>48 h) less likely to be symptomatic due to adaptation
  - adaptation: normalization of brain volume through loss of cellular electrolytes (within hours) and organic osmolytes (within days)
- neurologic symptoms predominate (secondary to cerebral edema): headache, nausea, malaise, lethargy, weakness, muscle cramps, anorexia, somnolence, disorientation, personality changes, depressed reflexes, decreased LOC

Symptoms of Central Pontine Myelinolysis
Cranial nerve palsies
Quadriplegia
Decreased LOC

Complications of Acute Hyponatremia

- cerebral edema and increased intracranial pressure resulting in nausea, headaches, decreased LOC, seizures, coma, brain herniation, and death

Correction of Na^+ in hyponatremia should not exceed 8 mmol/L/24 h unless definitely known to be <24-48 h duration; frequent monitoring of serum Na+ and urine output is essential

- risk of brain cell shrinkage with rapid correction of hyponatremia
  - can develop osmotic demyelination of pontine and extrapontine neurons; may be irreversible (e.g. central pontine myelinolysis)
  - symptom onset may be delayed 2-6 d; begins as dysarthria, dysphagia, paresis, movement disorders → later on seizures, lethargy, confusion, disorientation, obtundation, coma

Risk Factors for Osmotic Demyelination

- low serum [Na^+] of ≤115 mmol/L at presentation and/or duration of hyponatremia ≥2 d
- associated hypokalemia, malnutrition, liver disease, alcoholism
- overly rapid correction of [Na^+], i.e. rise in [Na^+] >8 mmol/L/24 h if chronic hyponatremia, e.g.:
  - inappropriate sodium replacement
  - restoration of euvolemia leading suppression of ADH by restoring euvolemia with isotonic fluid, or by stopping a reversible stimulus of SIADH (organic disorders; medications e.g. SSRIs; limbic system activation e.g. nausea, pain, surgical stress; see *Table 5, NP11*)
  - discontinuation of thiazides; depriving water in patient with psycgenic polydipsia

Investigations for Hyponatremia

- ECF volume status assessment (see *Table 4, NP9*)
- serum electrolytes, glucose, Cr
- serum osmolality, urine osmolality
- urine Na^+ (urine Na^+ <10-20 mmol/L suggests volume depletion as the cause of hyponatremia)
- assess for causes of SIADH (see *Table 5, NP11*)
- TSH, free T4, and cortisol levels
- consider CXR and possibly CT chest if suspect pulmonary cause of SIADH (e.g. paraneoplastic syndrome by small cell lung cancer)
- consider CT head if suspect CNS cause of SIADH (e.g. subarachnoid hemorrhage)

Beware of Rapid Correction of Hyponatremia

Rapid correction of hyponatremia can occur inadvertently, commonly after stopping a reversible secondary cause of SIADH, e.g.:

Patient with SIADH secondary to nausea is given an anti-emetic

Resolution of nausea causes a rapid cessation of SIADH, leading to renal excretion of excess water and rapid increase in serum [Na+]

Patient at risk of osmotic demyelination

High output dilute urine (>100 cc/h, <100 mOsm/L) in the setting of hyponatremia is usually the first sign of dangerously rapid correction of serum sodium

Treatment of Hyponatremia

- general measures for all patients
  1. restrict free water intake (<500-1500 ml/d depending on severity of hyponatremia)
  2. treat underlying cause (e.g. restore ECF volume if volume depleted, remove offending drug, treat pain, nausea, etc.)
  3. if euvolemic or hypervolemic hyponatremia, promote free water loss - furosemide or urea tablets
  4. carefully monitor serum Na^+, urine volume, and urine osmolality
  5. frequent monitoring for rapid overcorrection - brisk urine output (free water diuresis), frequent urine and serum electrolytes
- monitor urine output frequently: high output of dilute urine is the first sign of dangerously rapid correction of hyponatremia as the stimulus for ADH is diminished with the correction of hypovolemia

Concentration of [Na^+] in Common Infusates

- [Na^+] in 0.45% NaCl = 77 mmol/L
- [Na^+] in 0.9% NaCl = 154 mmol/L
- [Na^+] in 3% NaCl = 513 mmol/L
- [Na^+] in 5% NaCl = 855 mmol/L
- [Na^+] in Ringer's lactate = 130 mmol/L
- [Na^+] in D5W = 0

A. Known Acute (known to have developed over <48 h)

- commonly occurs in hospital (dilute IV fluid, postoperative increased ADH)
- less risk from rapid correction since adaptation has not fully occurred
- if symptomatic
  - correct rapidly with 3% NaCl at 1-2 cc/kg/h up to serum [Na^+] = 125-130 mmol/L
  - may need furosemide to address volume overload
- if asymptomatic, treatment depends on presence of risk factors for ODS and volume status (see next section)
  - goal is to promote a negative balance of free water
  - restrict free water intake
  - promote free water loss by administration of furosemide with salt tablets, oral urea, or vasopressin receptor 2 antagonists (e.g. tolvaptan)
  - if ODS risk factors present, aim to correct serum sodium more slowly
  - do not give 3% NaCl if hyponatremia is autocorrecting due to water diuresis

B. Chronic and Asymptomatic

1. if severe symptoms (seizures or decreased LOC)
   - must partially correct acutely
   - aim for increase of Na^+ by 0.5-1 mmol/L/h for 4-6 h
   - limit total rise to 8 mmol/L in 24 h
   - IV 3% NaCl at 1-2 cc/kg/h
   - may need furosemide
2. if asymptomatic
   - water restrict to <1 L/d fluid intake
   - consider IV 0.9% NS + furosemide (reduces urine osmolality, augments excretion of H_2O)
   - consider NaCl tablets as a source of Na^+
3. refractory
   - furosemide and oral salt tablets
   - oral urea (osmotic aquaresis)
   - vasopressin receptor 2 antagonists (e.g. tolvaptan)
4. always pay attention to patient's ECF volume status – if already volume-expanded, usually don't give NaCl (tablet or IV); if already volume-depleted, almost never appropriate to give furosemide

C. Options for Treatment of Overly-Rapid Correction

- give water (IV D5W)
- give DDAVP (synthetic ADH analogue) to stop water diuresis (DDAVP 1-4 μg IV q8H as needed)

Impact of IV Solution on Serum [Na+]
- formula to estimate the change in serum [Na +] caused by retention of 1 L of any infusate
- [TBW = (for men) 0.6 x weight(kg); (for women) 0.5 x weight(kg)]

SYNDROME OF INAPPROPRIATE ANTIDIURETIC HORMONE SECRETION
1. urine that is inappropriately concentrated for the serum osmolality
2. urine sodium >20-40 mmol/L – likely reflecting euvolemia
3. FE_{Na} >1%

Table 5. Disorders Associated with SIADH

Cancer	Pulmonary	CNS	Drugs	Miscellaneous
Small cell cancer Bronchogenic carcinoma Pancreatic adenocarcinoma Hodgkin's lymphoma Thymoma Leukemia	Pneumonia Lung abscess Tuberculosis Acute respiratory failure Asthma COPD Positive pressure ventilation	Mass lesion Encephalitis Subarachnoid hemorrhage Stroke Head trauma Acute psychosis Acute intermittent porphyria	Antidepressants TCAs SSRIs Antineoplastics Vincristine Cyclophosphamide Anti-epileptics Carbamazepine Barbiturates Chlorpropamide ACEI Other DDAVP Oxytocin Nicotine	Postoperative state Pain Severe nausea HIV

Hypernatremia

Definition
- serum [Na +] >145 mmol/L
- too little water relative to total body Na +; always a hyperosmolar state
- usually due to NET water loss or insufficient intake, rarely due to hypertonic Na +gain
- less common than hyponatremia because patients are protected against hypernatremia by thirst and release of ADH

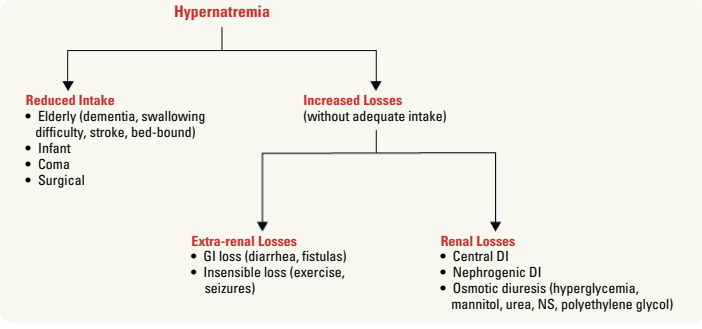

Figure 6. Approach to hypernatremia

Signs and Symptoms
- hypernatremia = shrunken cells
  - acute hypernatremia (<48 h)
  - chronic hypernatremia (>48 h), cells will have achieved adaptive mechanism: can import and generate new osmotically active particles to normalize cell size
  - nearly all cases of hypernatremia will be due to chronic hypernatremia
  - acute hypernatremia primarily presents in patients with diabetes insipidus, post obstructive diuresis, and post ATN diuresis (without free water access)
  - symptoms due to brain cell shrinkage: altered mental status, weakness, neuromuscular irritability, focal neurologic deficits, seizures, coma, death
- ± polyuria, thirst, signs of hypovolemia

Complications
- increased risk of vascular rupture resulting in intracranial hemorrhage
- rapid correction may lead to cerebral edema

H_2O Deficit and TBW Equations
TBW = 0.6 x wt (kg) men
TBW = 0.5 x wt (kg) women

H_2O deficit = TBW x ([Na^+]plasma – 140) / 140

Correction of serum [Na^+] in hypernatremia should not exceed 12 mmol/L/24 h

1 L D5W approximately equals 1 L of free water
1 L 0.45% NS approximately equals 500 mL of free water

Outcomes in Severe Hyponatremia Treated With and Without Desmopressin
Am J Med 2018;131:1-317
Purpose: Rapid overcorrection of plasma Na+ in severe hyponatremia can lead to osmotic demyelination syndrome. This study seeks to compare outcomes in hyponatremia based on DDAVP usage in treatment.
Methods: Retrospective study including all admissions to internal medicine with hyponatremia (plasma Na+ <123 mEq/L) from 2004 to 2014 at 2 Toronto hospitals. The primary outcome was safe Na+ correction (<12 mEq/L in any 24 h period and <18 mEq/L in any 48 h period), time to reach Na+ >130 mEq/L or hospital discharge. DDAVP uses were excluded for DI and for bleeding prevention in thrombocytopenia.
Results: Among 1450 admissions of 1274 patients for hyponatremia over the 10 yr period, desmopressin was administered in 254 admissions (17.5%). Fewer patients receiving DDAVP achieved safe Na+ correction within the 24 h time frame (70.9% vs. 85%; P<0.001). The proportion of cases with safe Na+ correction was highest in the proactive-DDAVP treatment group, followed by reactive then rescue treatment (78.6% for proactive vs. 29.3% for reactive). According to clinical or radiographic findings, 4 of 1450 admissions had suspected osmotic demyelination syndrome, two of which occurred during DDAVP administration (0.79% incidence, 95% CI 0.22-2.82).
Conclusions: The rescue strategy of DDAVP administration is not an ideal strategy, while the proactive strategy was effective at slowing Na+ rate of change. In patients at risk for osmotic demyelination syndrome, a proactive DDAVP strategy more often achieved a more stringent correction limit.

Treatment of Hypernatremia

- general measures for all patients
  - give free water (oral or IV)
  - treat underlying cause
  - monitor serum Na^+ frequently (q4h) to ensure correction is not occurring too rapidly
- if evidence of hemodynamic instability, then must first correct volume depletion with NS bolus
- loss of water is often accompanied by loss of Na^+, but a proportionately larger water loss
- encourage patient to drink pure water, as PO is preferred for fluid administration
- if unable to replace PO or NG, correct H_2O deficit with hypotonic IV solution (IV D5W, 0.45% NS [half normal saline], or 3.3% dextrose with 0.3% NaCl ["2/3 and 1/3"])
- chronic hypernatremia: aim to lower serum sodium by 8-10 mEq/L in 24 h (often achieved by giving free water at 1.35 mL/kg/h)
- acute hypernatremia: use formula to calculate water deficit. Replace entire water deficit within 24 h (hourly infusion rate = water deficit in mL/24 h)
- infusion rate may need to be increased in order to account for ongoing losses in addition to initial deficit

Diabetes Insipidus

Definition

- collecting tubule is impermeable to water due to absence of ADH or impaired response to ADH
- defect in central release of ADH (central DI) or renal response to ADH (nephrogenic DI)

Etiology

- central DI: neurosurgery, granulomatous diseases, trauma, vascular events, and malignancy
- nephrogenic DI
  - usually acquired – drugs (e.g. lithium), secondary to amyloidosis, sickle cell disease, Sjogren syndrome, polycystic kidney disease, electrolyte imbalances (i.e. hypercalcemia)
  - congenital/hereditary
  - post ATN diuresis
  - post obstructive diuresis

Diagnosis

- urine osmolality inappropriately low in patient with hypernatremia (U_{osm} <300 mOsm/kg)
- serum vasopressin concentration may be absent/low (central), or elevated (nephrogenic)
- dehydration test: H_2O deprivation until loss of 3% of body weight or until urine osmolality rises above plasma osmolality and/or Na increases over 146; if urine osmolality remains <300 (fails to concentrate urine), most likely DI

Management

- central DI: administer exogenous ADH (e.g. DDAVP) 10 µg intranasally or 2 µg SC or IV
- nephrogenic DI: patients may have partial or complete ADH resistance, and DDAVP is generally ineffective
  - maintain fluid intake to match losses, e.g. PO water, IV D5W, IV 0.45% NS
  - treat underlying cause of nephrogenic DI
  - thiazides can help by paradoxically reducing urine output: thiazides induce hypovolemia → stimulate proximal tubular reabsorption of sodium and water → less delivery of glomerular filtrate to the collecting duct → lower urine volume

A Copeptin-Based Approach to the Diagnosis of Diabetes Insipidus
NEJM 2018;379:428-39
Purpose: Comparison of the indirect water-deprivation test, a technically cumbersome test, with direct detection of plasma copeptin, a precursor-derived surrogate of arginine vasopressin.
Methods: From 2013 to 2017, 156 patients with hypotonic polyuria underwent both indirect water-deprivation testing and hypertonic saline infusion tests. In the latter test, plasma copeptin levels were measured when plasma Na+ increased to >150 mmol/L after saline infusion. The primary outcome was overall diagnostic accuracy of each test compared with final reference diagnosis, as determined by clinical history, test results and treatment response, with copeptin levels masked.
Results: Among the 141 patients included in final analysis, the indirect water-deprivation test showed diagnostic accuracy in 108 patients (76.6%; 95% CI 68.9 to 83.2) and the hypertonic saline infusion (copeptin cutoff >4.9 mmol/L) showed diagnostic accuracy in 136 patients (96.5%; 95% CI 92.1 to 98.6, P<0.001). The water-deprivation test correctly distinguished primary polydipsia from partial central DI in 77 of 105 patients (73.3%; 95% CI 63.9 to 81.2) while the hypertonic saline test distinguished in 99 of 104 patients (95.2%; 95% CI 89.4 to 98.1, P<0.001).
Conclusion In patients with hypotonic polyuria, direct measurement of hypertonic-saline stimulated plasma copeptin levels showed greater diagnostic accuracy than the water-deprivation test.

Potassium Homeostasis

- ~98% of total body K^+ stores are intracellular
- normal serum K^+ ranges from 3.5-5.0 mEq/L
- in response to K^+ rise, rapid removal from ECF is necessary to prevent life-threatening hyperkalemia (K+ >6.5 mEq/L)
- insulin, catecholamines, and acid-base status influence K^+ movement into cells
  - aldosterone has a minor effect
- potassium excretion is regulated at the DCT and collecting ducts
  - K^+ excretion = urine flow rate x urine $[K^+]$

Factors which Increase Renal K^+ Loss

- hyperkalemia
- increased distal tubular urine flow rate and Na^+ delivery (thiazides and loop diuretics)
- increased aldosterone activates epithelial sodium channels in cortical collecting duct, causing Na^+ reabsorption and K^+ excretion
- metabolic alkalosis (increases K^+ secretion)
- hypomagnesemia
- increased non-resorbable anions in tubule lumen: HCO_3^-, penicillin, salicylate (increased tubular flow rate increases K^+ secretion)

Hypokalemia

Definition

- serum [K^+] <3.5 mEq/L

Signs and Symptoms

- usually asymptomatic, particularly when mild (3.0-3.5 mmol/L)
- nausea/vomiting, fatigue, generalized weakness, myalgia, muscle cramps, and constipation
- if severe: arrhythmias, rhabdomyolysis, myoglobinuria, and rarely paralysis with eventual respiratory impairment
- arrhythmias occur at variable levels of K^+; more likely with digoxin use, hypomagnesemia, or CAD
- ECG changes are more predictive of clinical picture than serum [K^+]
  - U waves most important (low amplitude wave following a T wave)
  - flattened or inverted T waves
  - depressed ST segment
  - prolongation of Q-T interval
  - sinus bradycardia
  - with severe hypokalemia: P-R prolongation, wide QRS, arrhythmias; increases risk of digitalis toxicity
  - common arrhythmias seen with hypokalemia: ventricular fibrillation, ventricular tachycardia

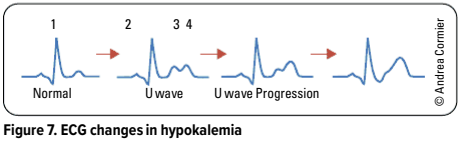

Figure 7. ECG changes in hypokalemia

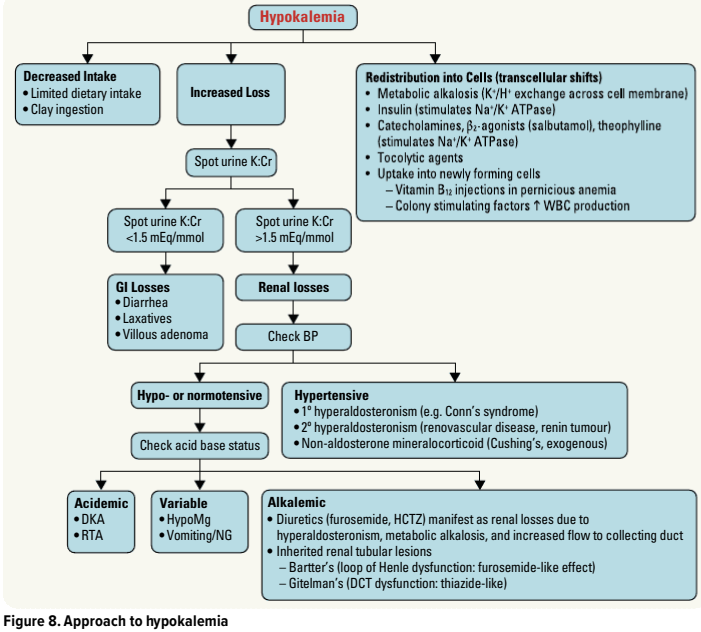
Approach to Hypokalemia

1. emergency measures if K^+<2.5 mEq/L: obtain ECG; if potentially life threatening, begin treatment immediately
2. rule out transcellular shifts of K^+as cause of hypokalemia
3. assess contribution of dietary K^+ intake
4. spot urine K:Cr
   - if <1.5 mEq/mmol consider GI loss
   - if >1.5 mEq/mmol consider a renal loss
5. consider 24 h K^+excretion
6. if renal K^+loss, check BP and acid-base status
7. may also assess plasma renin and aldosterone levels, serum [Mg^{2+}]

Hypokalemia is often accompanied by metabolic alkalosis:

- K^+shifts from cells to ECF; H^+shifts into cells in response
- Plasma [HCO_3^-] increases, while intracellular pH decreases
- In response to low pH, renal tubular cells secrete H^+into lumen, and increase renal ammoniagenesis and excretion
- Resultant addition of more [HCO_3^-] into plasma → metabolic alkalosis



Hypokalemia
Decreased Intake
• Limited dietary intake
• Clay ingestion
Increased Loss
Redistribution into Cells (transcellular shifts)
• Metabolic alkalosis (K^+/H^+ exchange across cell membrane)
• Insulin (stimulates Na^+/K^+ ATPase)
• Catecholamines, β_2-agonists (salbutamol), theophylline (stimulates Na^+/K^+ ATPase)
• Tocolytic agents
• Uptake into newly forming cells
– Vitamin B_{12} injections in pernicious anemia
– Colony stimulating factors ↑ WBC production
Spot urine K:Cr
Spot urine K:Cr <1.5 mEq/mmol
Spot urine K:Cr >1.5 mEq/mmol
GI Losses
• Diarrhea
• Laxatives
• Villous adenoma
Renal losses
Check BP
Hypo- or normotensive
Hypertensive
• 1° hyperaldosteronism (e.g. Conn's syndrome)
• 2° hyperaldosteronism (renovascular disease, renin tumour)
• Non-aldosterone mineralocorticoid (Cushing's, exogenous)
Check acid base status
Acidemic
• DKA
• RTA
Variable
• HypoMg
• Vomiting/NG
Alkalemic
• Diuretics (furosemide, HCTZ) manifest as renal losses due to hyperaldosteronism, metabolic alkalosis, and increased flow to collecting duct
• Inherited renal tubular lesions
– Bartter's (loop of Henle dysfunction: furosemide-like effect)
– Gitelman's (DCT dysfunction: thiazide-like)

Figure 8. Approach to hypokalemia

Treatment
- treat underlying cause
- if true K^+deficit, potassium repletion
  - oral sources: food, tablets (K-Dur™), KCl liquid solutions (preferable route if the patient tolerates PO medications)
  - IV: usually KCl in saline solutions, avoid dextrose solutions (may exacerbate hypokalemia via insulin release)
- max 40 mmol/L via peripheral vein, 60 mmol/L via central vein, max infusion 20 mmol/h
- K^+-sparing diuretics (triamterene, amiloride, spironolactone) can prevent renal K^+loss
- restore Mg^{2+}before correcting K^+
- if urine output and renal function are impaired, correct with extreme caution
- risk of hyperkalemia with potassium replacement especially high in elderly, diabetics, and patients with decreased renal function
- use ACE inhibitor or ARB for CHF (reduces angiotensin II action and therefore reduces aldosterone production)
- beware of excessive potassium repletion, especially if hypokalemia secondary to transcellular shift

Hyperkalemia

Definition
- serum $[K^+]$ >5.0 mEq/L

Signs and Symptoms
- usually asymptomatic but may develop nausea, palpitations, muscle weakness, muscle stiffness, paresthesias, areflexia, ascending paralysis, and hypoventilation
- impaired renal ammoniagenesis and excretion and metabolic acidosis
- ECG changes and cardiotoxicity (do not correlate well with serum $[K^+]$)
- peaked and narrow T waves
- decreased amplitude and eventual loss of P waves
- prolonged PR interval
- widening of QRS and eventual merging with T wave (sine-wave pattern)
- AV block
- ventricular fibrillation, asystole

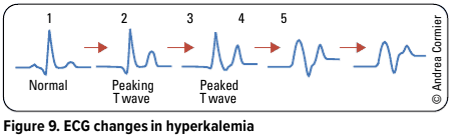


Figure 9. ECG changes in hyperkalemia

Table 6. Causes of Hyperkalemia

Pseudohyperkalemia	Increased Intake	Transcellular Shift	Decreased Excretion
Sample hemolysis*	Diet	Intravascular hemolysis	Decreased GFR
Sample taken from vein where IV KCl is running	KCl tabs	Rhabdomyolysis	Renal failure
Prolonged use of tourniquet	IV KCl	Tumour lysis syndrome	Low effective circulating volume
Leukocytosis (extreme)	Salt substitute	Insulin deficiency	NSAIDs in renal insufficiency
Thrombocytosis** (extreme)		Metabolic Acidosis	Normal GFR but hypoaldosteronism (Table 7)
		Drugs	
		β-blockers	
		Digitalis overdose (blocks Na^+/K^+ ATPase)	
		Succinylcholine	

*Most common
**Usually when blood specimen has been sitting out long before being analyzed

Table 7. Causes of Hyperkalemia with Normal GFR Secondary to Hypoaldosteronism

Decreased Aldosterone Stimulus (low renin, low aldosterone)	Decreased Aldosterone Production (normal renin, low aldosterone)	Aldosterone Resistance (decreased tubular response)
Associated with diabetic nephropathy, NSAIDs, chronic interstitial nephritis, HIV	Adrenal insufficiency (e.g. Addison's disease, AIDS, metastatic cancer)	K^+-sparing diuretics:
	ACEI	Spironolactone
	Angiotensin II receptor blockers	Amiloride
	Heparin	Triamterene
	Congenital adrenal hyperplasia with 21-hydroxylase deficiency	Renal tubulointerstitial disease

Approach to Hyperkalemia
1. emergency measures: obtain ECG; if life threatening, begin treatment immediately
2. rule out pseudohyperkalemia; repeat blood test

In patients with DM and increased $[K^+]$ and hyperglycemia, often just giving insulin to restore euglycemia is sufficient to correct the hyperkalemia

3. hold exogenous K^+ (PO and IV) and any medications that are K^+ retaining
e.g. RAAS inhibitors (ACEI, ARBs), aldosterone antagonists, non-selective β-blockers (propranolol/labetalol) or affect K^+ excretion (i.e. NSAIDs)
4. assess potential causes of transcellular shift
5. determine eGFR

Treatment

- acute therapy is warranted if ECG changes are present or if patient is symptomatic regardless of $[K^+]$
- tailor therapy to severity of increase in $[K^+]$ and ECG changes
  - $[K^+]$ <6.5 and normal ECG
    - treat underlying cause, stop K^+ intake, increase the loss of K^+ via urine and/or GI tract
  - $[K^+]$ between 6.5 and 7.0, no ECG changes: add insulin to above regimen
  - $[K^+]$ >7.0 and/or ECG changes: first priority is to protect the heart, add calcium gluconate to above

1. Stabilize Myocardium

- calcium gluconate 1-2 amps (10 mL of 10% solution) IV
- antagonizes hyperkalemia induced membrane depolarization, protects cardiac conduction system, no effect on serum $[K^+]$
- onset within minutes, lasts 30-60 min (may require repeat doses during treatment course of hyperkalemia)

2. Shift K^+ into Cells

- regular insulin (Insulin R) 10-20 units IV, with 50-100 mL D50W to prevent hypoglycemia
  - onset of action 15-30 min, lasts 4-6 h
  - monitor capillary blood glucose q1h because of risk of hypoglycemia
  - can repeat q4-6 h
  - caution giving D50W before or without insulin if hyperkalemia is severe: hypertonic glucose increases plasma osmolality, promoting extracellular water and $^+$shift, and can cause a serious arrhythmia
- β2-agonist (Ventolin®) in nebulized form (dose = 2 cc or 10 mg inhaled) or 0.5 mg IV
  - onset of action 30-90 min, stimulates Na^+/K^+ ATPase
  - caution if patient has heart disease as may result in tachycardia

3. Enhance K^+ Removal from Body

- via urine (preferred approach)
  - furosemide (≥40 mg IV), may need IV NS to avoid hypovolemia
  - fludrocortisone (synthetic mineralocorticoid) if suspecting aldosterone deficiency
- via GI (if renal function is severely impaired)
  - cation exchangers: patiromer 8.4 g PO OD (up to 25.2 g/d), zirconium cyclosilicate, or sodium polystyrene sulfonate (Kayexalate®)
    - practically, patiromer and zirconium are not currently widely employed due to high cost
    - sodium polystyrene sulfonate (Kayexalate®) should be used with caution, as they may lead to the development of colonic necrosis and intestinal perforation, especially when used in combination with sorbitol
  - osmotic laxatives e.g. lactulose can support GI excretion of K^+ in the form of diarrhea
- dialysis (renal failure, life threatening hyperkalemia unresponsive to therapy)

Treatment of Hyperkalemia

C	Calcium gluconate
BIG	β-agonist, Insulin, Glucose
K	Kayexalate®
DROP	Diuretics, Dialysis

Acute Management of Hyperkalemia

Curr Heart Failure Rep 2019;16:67-74

Purpose: Outline and review the current evidence behind the acute medical management of hyperkalemia, including the three principal strategies of stabilizing the myocardium, intracellular shifting of serum K^+, and enhancing elimination via urinary or fecal excretion.

1. Stabilizing the Myocardium: The protective effects of Ca^{2+} salts on myocardial stabilization should be seen within 5 min of administration. Doses can be repeated in 5 min intervals if life-threatening ECG changes persist. There are concerns regarding calcium use in digoxin toxicity causing irreversible non-contractile states. No life-threatening dysrhythmias occurred within 1 h of calcium administration.
2. Intracellular Shifting of Potassium: Regular insulin has shown effectiveness at decreasing serum K^+, with IV insulin decreasing serum K^+ by 0.8 mmol/L at 1 h. The main side effect of insulin-induced hypoglycemia can be managed with IV dextrose. Albuterol has an onset within 15-30 min of administration, causing maximal decreases by 1 mmol/L at 1 h. There is little evidence to suggest that sodium bicarbonate has a role in the management of hyperkalemia, except in the case of concomitant metabolic acidosis.
3. Enhanced Excretion: Though limited evidence for acute management, it is recommended to administer loop diuretics and sodium polystyrene sulfonate to eliminate K^+. Diuretics may precipitate or worsen AKI in patients with poor volume status, while sodium polystyrene sulfonate should be used with caution due to severe GI side effects such as ulceration, bleeding, colonic ischemia/necrosis, and intestinal perforation.

Hyperphosphatemia

Definition

- serum phosphate >1.45 mmol/L
  - phosphate binds to serum calcium to create insoluble precipitates in soft tissues and blood vessels, thereby resulting in hypocalcemia
  - hypocalcemia subsequently triggers the development of secondary hyperparathyroidism in patients with advanced CKD on dialysis

Etiology

- typically results from decreased renal excretion of phosphate

Table 8. Etiology of Hyperphosphatemia

Increased Phosphate Load	Reduced Renal Clearance	Pseudohyperphosphatemia
GI intake (rectal enema, GI bleeding) IV phosphate load (K-Phos®, blood transfusion) Endogenous phosphate (tumour lysis syndrome, rhabdomyolysis, hemolysis, lactic and ketoacidosis)	Acute/chronic renal failure Hypoparathyroidism Acromegaly Tumour calcinosis (ability of kidney to specifically clear phosphate is defective)	Hyperglobulinemia Hyperlipidemia Hyperbilirubinemia

Clinical Features

- non-specific, include ectopic calcification in soft tissues and vessels, renal osteodystrophy
  - symptoms consistent with hypocalcemia

Symptoms of Hypocalcemia

Tetany
Seizures
Hypotension
QT prolongation
Papilledema
Psychiatric manifestations

Treatment
- acute: IV saline, hemodialysis if symptomatic;
- chronic: low PO_4^{3-} diet, phosphate binders (e.g. $CaCO_3$, lanthanum carbonate, sevelamer with meals)

Hypophosphatemia

Definition
- serum phosphate <0.80 mmol/L

Etiology
- acute hypophosphatemia often caused by intracellular shifts of phosphate superimposed on chronic phosphate depletion
- chronic hypophosphatemia often caused by decreased renal phosphate reabsorption
- severe chronic hypophosphatemia often caused by chronic starvation or malabsorption (e.g. in patients with alcoholism) or chronic use of phosphate binders (e.g. patients with CKD)

Table 9. Etiology of Hypophosphatemia

Inadequate Intake	Renal Losses	Excessive Skeletal Mineralization	Shift into Intracellular Fluid
Starvation Malabsorption (diarrhea, steatorrhea) Antacid use Alcoholism	Hyperparathyroidism Diuretics X-linked or autosomal dominant hypophosphatemic Rickets Fanconi syndrome Multiple myeloma Early postrenal transplant	Osteoblastic metastases Post parathyroidectomy (referred to as 'hungry bone syndrome')	Recovery from metabolic acidosis Respiratory alkalosis Starvation refeeding (stimulated by insulin)

Symptoms usually present when phosphate <0.32 mmol/L (1.0 mg/dL)
Treat asymptomatic patients if phosphate <0.32 mmol/L

Severe burns can cause hypophosphatemia due to PO_4^{3-} losses through the skin

Clinical Features
- instability of cell membranes leading to hemolytic anemia or rhabdomyolysis
- MSK weakness, respiratory depression, low cardiac output/CHF from weakened cardiac muscles: symptoms arise due to low ATP production
- neurological symptoms: irritability, encephalopathy, seizures, coma
- hematologic symptoms: hemolytic anemia, decreased release of oxygen from hemoglobin, impaired leukocyte and platelet function (leading to worsening infections/defective clotting)

Treatment
- treat underlying cause
- initiate when serum $[PO_4^{3-}]$ <0.64 mmol/L. Use PO therapy if asymptomatic, or symptomatic and $[PO_4^{3-}]$ >0.32 mmol/L. Use IV therapy if symptomatic and $[PO_4^{3-}]$ <0.32 mmol/L
  - PO PO_4^{3-}: 2-4 g/d divided BID-QID (start at 1 g/d to minimize diarrhea), encourage PO_4^{3-} rich diet
  - IV PO_4^{3-}: only for severely symptomatic patients or inability to tolerate oral therapy

Hypermagnesemia

Definition
- serum magnesium >1.05 mmol/L

Etiology
- AKI/CKD
- Mg^{2+}-containing antacids or enemas
- IV administration of large doses of $MgSO_4$ (e.g. see Obstetrics, *Preeclampsia*, OB26)

Clinical Features
- rarely symptomatic
- drowsiness, hyporeflexia, respiratory depression, heart block, cardiac arrest, hypotension

Treatment
- discontinue Mg^{2+}-containing products
- 10% calcium gluconate 10-20 mL IV (Mg^{2+} -antagonist) for acute reversal of magnesium toxicity
- hemodialysis if renal failure, consider peritoneal dialysis in setting of hemodynamic compromise

Hypomagnesemia

Definition

- serum magnesium <0.70 mmol/L

Etiology

GI losses	Excess renal loss
Starvation/malabsorption	2° hyperaldosteronism due to cirrhosis and CHF
Vomiting/diarrhea	Hyperglycemia
Alcoholism	Hypokalemia
Acute pancreatitis	Hypercalcemia
	Loop and thiazide-type diuretics
	Nephrotoxic medications
	Proton-pump inhibitors
	Early postrenal transplant

You will be unable to correct hypokalemia or hypocalcemia without first supplementing magnesium if patient is hypomagnesemic

Clinical Features

- tremors, nausea and vomiting, lethargy/weakness, seizures, paresis, Chvostek and Trousseau signs, ECG changes (widened QRS, prolonged PR, T-wave abnormalities), and arrhythmias including Torsades de Pointes

Treatment

- treat underlying cause
- encourage increased dietary intake e.g. fruits
- oral Mg^{2+}salts unless patient has seizures or other severe symptoms
- Mg^{2+}IM/IV; cellular uptake of $Mg^{2+}$is slow, therefore repletion requires sustained correction
- discontinue diuretics
  - in patients requiring diuretics, use a K^{+}-sparing diuretic to minimize magnesuria

Acid-Base Disorders

- acid-base homeostasis influences protein function and can critically affect tissue and organ function with consequences to cardiovascular, respiratory, metabolic, renal, and CNS function
- normal concentration of $[HCO_3^-]$= 24 mEq/L (range: 21–27 mEq/L for arterial blood gas sample)
- normal pCO_2 = 40 mmHg (range: 36-44 mmHg)
- each acid-base disorder has an associated compensation
  - inadequate compensation or overcompensation can indicate the presence of a second acid-base disorder (e.g. in metabolic acidosis, inadequate compensation means there is also respiratory acidosis; overcompensation means there is also respiratory alkalosis)
- most commonly assessed using an arterial blood gas sample
- see Respirology, R5 for more information on respiratory acidosis/alkalosis

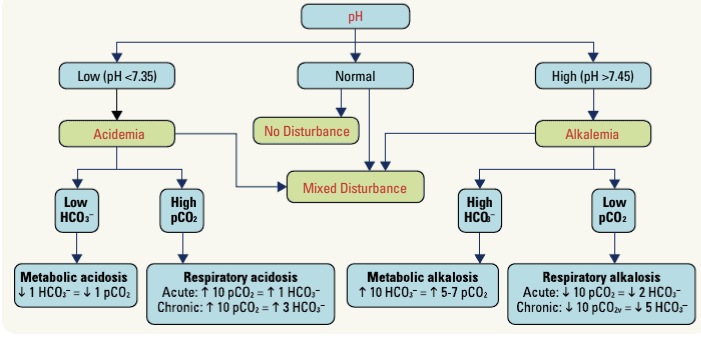

Figure 10. Approach to acid-base disorders. Equalities represent the appropriate compensatory changes in pCO_2 or HCO_3 in response to the primary disturbance

Causes of Increased Osmolar Gap

Methanol
Ethylene glycol
Ethanol
Polyethylene glycol
Mannitol
Sorbitol

Useful Equations

AG = [Na+] - [Cl^-] - [HCO_3^-] (normal range = 10-14 mEq/L)

Osmolar Gap = measured serum osmolality – calculated osmolality (normal <10 mEq/L)
– "Two Salts and a Sticky BUN"

Calculated Osmolality = 2[Na+] + [Urea] + [Glucose] (+1.25[Ethanol])

Approach

1. Identify the Primary Disturbance

- respiratory acidosis, metabolic acidosis, respiratory alkalosis, metabolic alkalosis

2. Evaluate Compensation. If compensation is not appropriate, second acid-base disorder is likely present

- compensation occurs in the same direction as the primary disturbance

3. Calculate Plasma AG
- AG = [Na^+] – ([HCO_3^-] + [Cl^-])
- baseline = 12, normal range 10-14 mEq/L
- AG can be altered by plasma albumin level: for each 10 g/L fall in albumin, lower baseline AG by 3 mEq/L (e.g. if plasma [albumin] = 20 g/L, expect AG = 6 mEq/L)
  - albumin is an unmeasured polyanion largely responsible for the normal anion gap

4. Calculate Osmolar Gap
- osmolar gap = measured osmolality – calculated osmolality
  - calculated osmolality = (2 x [Na^+]) + [urea] + [glucose] (all units are in mmol/L)
  - normal osmolar gap <10
  - If OG >10, consider methanol poisoning, ethylene glycol poisoning, or another cause of acidosis plus ethanol ingestion

5. If AG elevated, compare increase in AG with decrease in HCO_3^-b
- if increase in AG < decrease in HCO_3^-, there is a co-existing non-AG metabolic acidosis
- if increase in AG > decrease in HCO_3^-, there is a co-existing metabolic alkalosis

Metabolic Acidosis

• characterized by decreased blood pH (<7.35) and a decreased bicarbonate concentration

Clinical Features
• hyperventilation (Kussmaul Breathing)
• decreased cardiac output and tissue perfusion (reduced responsiveness to catecholamines)

Etiology and Pathophysiology
1. increased AG metabolic acidosis (4 types)
   - lactic acidosis (2 types)
     - L-lactic acid
       - type A: due to tissue hypoperfusion (any cause of shock), ischemic bowel, profound hypoxemia
       - type B: non-hypoxic – multiple causes; the most common is failure to metabolize normally produced lactic acid in the liver due to severe liver disease; other causes include: excessive alcohol intake, thiamine deficiency, metformin accumulation (metformin interferes with electron transport chain), certain antiretrovirals, large tumours, mitochondrial myopathies, cyanide poisoning
     - D-lactic acid: rare syndrome characterized by episodes of encephalopathy and metabolic acidosis
       - occurs in the setting of carbohydrate malabsorption (e.g. short bowel syndrome), colonic bacteria metabolize carbohydrate load into D-lactic acid, diminished colonic motility, and impaired D-lactate metabolism
   - ketoacidosis
     - diabetic
     - starvation
     - alcoholic (decreased carbohydrate intake and vomiting)
   - toxins
     - methanol (toxic to brain and retina, can cause blindness and brain death): metabolized to formic acid
     - ethylene glycol (toxic to brain and kidneys): metabolized to oxalic acid (envelope shaped crystals in urine) and multiple other acids
     - salicylate (e.g. ASA) overdose: causes acidosis due to salicylic acid, and also accumulation of lactic acid (salicylate at toxic levels impairs electron transport chain) and ketoacids (salicylate activates fat breakdown)
   - advanced renal failure
     - e.g. serum Cr increased at least 5x above baseline – a very low GFR causes retention of $H^+$and decreased NH_4^+ excretion; the retained acid is buffered by bicarbonate resulting in reduced serum concentrations of bicarbonate

2. non-AG metabolic acidosis (hyperchloremic acidosis; involves increased bicarbonate excretion that is replaced with Cl^-)
   - diarrhea (HCO_3^-loss from GI tract)
   - RTA
     - type I RTA (distal): inability to secrete H^+in collecting duct, leading to impaired excretion of ammonium into urine
     - type II RTA (proximal): impaired HCO_3^-reabsorption
     - type III RTA: combination of Types I and II and is extremely rare
     - type IV RTA: defective ammoniagenesis characterized by hyperkalemia, due to decreased or hyporesponsiveness to aldosterone
   - to help distinguish renal causes from non-renal causes, use Urine AG = (Na^++ K^+) – Cl^-

Causes of Increased AG Metabolic Acidosis

MUDPILES CAT
Methanol
Uremia
Diabetic ketoacidosis
Paraldehyde
Isopropyl alcohol/Iron/Ibuprofen/Indomethacin
Lactic acidosis
Ethylene glycol
Salicylates
Cyanide and Carbon monoxide
Alcoholic ketoacidosis
Toluene

Causes of Non-AG Metabolic Acidosis

HARDUP
Hyperalimentation
Acetazolamide
RTA*
Diarrhea*
Ureteroenteric fistula
Pancreaticoduodenal fistula

*Most common

3 Clinical Scenarios that Produce a Mixed Disorder with Near Normal pH (e.g. increased AG metabolic acidosis + respiratory alkalosis)
- Cirrhosis
- ASA overdose
- Sepsis

- calculation establishes the presence or absence of unmeasured positive ions (e.g. NH_4^+) in urine
  - if UAG <0, suggests adequate NH_4^+ excretion in urine (likely non-renal cause: diarrhea)
  - if UAG >0, suggests problem is lack of NH_4^+ in urine (likely renal cause: distal RTA)

Evaluation

- a detailed history and physical exam with serum or plasma electrolytes, and calculation of anion gap is usually sufficient to determine the cause of metabolic acidosis and guide therapy, but in more complicated patients measurement of pH and pCO_2 and determining whether respiratory compensation is appropriate can provide a definitive evaluation

Treatment of Metabolic Acidosis

1. treat underlying cause, e.g.:
   - in DKA: fluid resuscitation, K^+ supplementation, and insulin
   - in Type A lactic acidosis: restore tissue perfusion
   - in methanol or ethylene glycol poisoning: ethanol/fomepizole ± dialysis
   - in ASA overdose: alkaline diuresis ± dialysis
2. correct coexisting disorders of K^+ (see *Hyperkalemia, NP14*)
3. consider treatment with exogenous alkali (e.g. $NaHCO_3$) if:
   - severe reduction in $[HCO_3^-]$ e.g. <8 mmol/L, especially with very low pH (<7)
   - no metabolizable anion (e.g. salicylate, formate, oxalate, or sulphate); note that lactate and ketoacid anions can be metabolized to HCO_3^-

- note: risks of sodium bicarbonate therapy
  - hypokalemia: causes K^+ to shift into cells (correct K^+ deficit first)
  - ECF volume overload: Na^+ load given with $NaHCO_3$, can exacerbate pulmonary edema
  - overshoot alkalosis: abrupt, poorly tolerated transition from overly aggressive alkali loading, partial conversion of accumulated organic anions to HCO_3^-, and persisting hyperventilation

Metabolic Alkalosis

- characterized by increased blood pH (>7.45) and an increased bicarbonate concentration

Pathophysiology

- requires precipitating event and maintenance factors
- precipitating factors
  - GI (vomiting, NG tube) or renal loss of H^+
  - exogenous alkali (oral or parenteral administration), milk alkali syndrome (hypercalcemia)
  - loop/thiazide diuretics: increased distal H^+ secretion and proximal HCO_3^- reabsorption; ECF volume depletion also contributes to a contraction alkalosis
  - post-hypercapnia: renal compensation for respiratory acidosis is HCO_3^- retention, rapid correction of respiratory disorder results in transient excess of HCO_3^-
- maintenance factors
  - volume depletion: reduced GFR, increased proximal reabsorption of Na^+ and HCO3-, and increased aldosterone
  - hyperaldosteronism (1° or 2°): distal Na^+ reabsorption in exchange for K^+ and H^+ excretion leads to metabolic alkalosis and hypokalemia
  - hypokalemia: transcellular K^+/H^+ exchange, stimulus for ammoniagenesis and HCO_3^- generation

Evaluate Compensation (identify co-existing respiratory acid-base disorders)

- hypoventilation (an upper limit to compensation exists – breathing cannot be stopped)

Treatment

- correct underlying disease, replenish K^+ and Mg^{2+} deficits, and possibly K^+-sparing diuretic
- saline sensitive metabolic alkalosis (most common)
  - urine chloride <20 mEq/L, characterized by ECF contraction and hypokalemia
  - volume repletion ± carbonic anhydrase inhibitor (e.g. acetazolamide) to facilitate loss of HCO_3^- in urine
- saline resistant metabolic alkalosis
  - urine chloride >20 mEq/L, characterized by ECF expansion and hypertension (increased mineralocorticoids)
  - remove source of aldosterone or glucocorticoid ± spironolactone

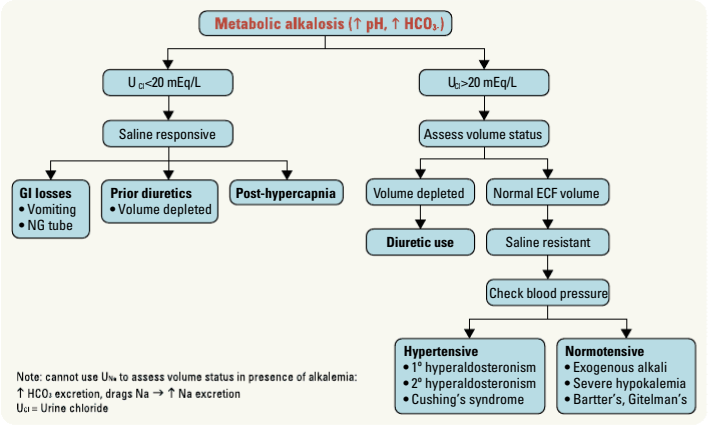

Figure 11. Approach to metabolic alkalosis

Polyuria

Definition

- output >3 L/d in adults and 2 L/m ^{2}in children. Distinguish from urinary frequency, where urination occurs multiple times per day but the total volume over 24 h is <3 L

Etiology

- either due to water diuresis or solute diuresis
- solute diuresis:
  - glucose (uncontrolled diabetes)
  - salt (increased salt intake or IV fluids with sodium)
  - urea (resolution of azotemia, intake of urea, tissue breakdown or metabolism)
- water diuresis:
  - diabetes insipidus (central or nephrogenic)
  - polydipsia (excess water drinking)
  - drugs (most commonly diuretics)

Clinical Features

- must distinguish between true polyuria and urinary frequency
- look for sources of external fluid intake (IV fluids, tube feedings)
- assess for neurological changes (stroke, trauma, postoperative) (for central diabetes insipidus). Assess for pituitary dysfunction
- assess for drugs that may cause nephrogenic diabetes insipidus (e.g. lithium)
- abrupt onset suggests central diabetes insipidus (deficient ADH)

Investigation Findings

- 24 h urine collection >3 L (in adults)
- laboratory findings that may point to specific etiologies:
  - hyperglycemia and/or glucosuria suggests osmotic diuresis secondary to uncontrolled diabetes mellitus
  - hyponatremia may suggest free water intake secondary to polydipsia
  - hypernatremia may suggest free water loss secondary to diabetes insipidus
- check urine osmolality:
  - U_{osm} <100 mOsm/kg, consider causes of water diuresis (DI, psychogenic polydipsia)
  - U_{osm} 100-300 mOsm/kg, consider causes of mixed polyuria (partial DI, CKD)
  - U_{osm} >300 mOsm/kg, consider causes of osmotic diuresis (hyperglycemia, azotemia, excess solute intake)
- water deprivation test if suspected DI, see *Diabetes Insipidus, NP12* for complete workup for diabetes insipidus

Treatment

- specific to etiology

Acute Kidney Injury

Definition

- abrupt decline in renal function leading to increased nitrogenous waste products normally excreted by the kidney
- formerly known as acute renal failure

Clinical Features

- decreased GFR
- may have weight gain and edema
- azotemia (increased BUN, Cr)
- abnormal urine volume: formally <0.5 ml/kg/h for >6 h but can manifest as anuria, oliguria, or polyuria

Table 10. Classification of Acute Kidney Injury

Stage	Serum Creatine	Urine output
1	.5-1.9 times baseline OR ≥0.3 mg/dl (>26.5 umol/l) increase	<0.5 ml/kg/h for 6-12 h
2	2.0-2.9 times baseline	<0.5 ml/kg/h for ≥12 h
3	3.0 times baseline OR Increase in serum creatine to ≥4.0 mg/dl (≥353.6 umol/l) OR Initiation of renal replacement therapy OR In patient <18 yr, decrease in eGFR to <35 ml/min per 1.73m^2	0.3 ml/kg/h for ≥24 h OR Anuria for ≥12 h

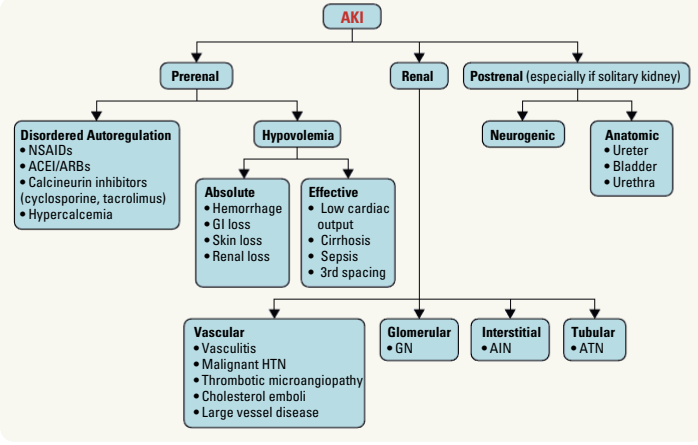

Figure 12. Approach to AKI

Investigations

- blood work: CBC, electrolytes, Cr, urea (think prerenal if increase in urea is relatively greater than increase in Cr), Ca^{2+}, PO_4^{3-}
- urine tests:
  - urine analysis: R and M, sediment, casts and crystals
  - urinary chemistry: electrolytes, osmolality, FENa
  - albumin, hemoglobin, WBCs, glucose, pH, urobilinogen, specific gravity
  - urine volume, C&S
- imaging: abdomen U/S (assess kidney size, hydronephrosis, postrenal obstruction)
- fluid challenge (e.g. fluid bolus to rule out most prerenal causes)
- indications for renal biopsy
  - diagnosis is not certain
  - prerenal azotemia or ATN is unlikely
  - oliguria persists >2-4 d
  - RPGN, signs of significant glomerular disease (proteinuria, RBC casts) despite normal kidney size/echogenicity

The 2 most common causes of acute kidney injury in hospitalized patients are prerenal azotemia (decreased perfusion) and ATN; remember that prerenal failure can lead to ATN

Differentiating Prerenal from ATN

	Prerenal	ATN
Urine Microscopy	Normal	RBC, pigmented granular casts
Urine [Na^+]	<20	>40 mEq/L
Urine osmolality	>500	<350 mOsm/kg H_2O
FENa	<1%	>2%
Plasma [Urea]/[Cr]	>20	>10-15
Response of Cr to fluid repletion	Return to baseline 1-3 d	Persistent elevation

Clues to Prerenal Etiology
- Clinical: Decreased BP, increased HR, and orthostatic HR and BP changes, oliguria
- Increased [urea] >> Increased [Cr]
- Urine [Na^+] <10-20 mmol/L
- Urine osmolality >500 mOsm/kg
- Fractional excretion of Na $^+$<1%

Clues to Renal Etiology
- Appropriate clinical context
- Urinalysis positive for casts:
  - Pigmented granular – ATN
  - WBC – AIN
  - RBC – GN
- Systemic features, anemia, thrombocytopenia, HTN, mild-moderate ECF volume overload

Clues to Postrenal Etiology
- Known solitary kidney
- Older man
- Recent retroperitoneal surgery
- Anuria
- Palpable bladder
- Ultrasound shows hydronephrosis
- Fractional excretion of Na $^+$>2-3 %
- Urine osmolality 250-300 mOsm/kg

Avoid NSAIDs in patients with diarrhea, heart failure, or renal failure

Renal transplant is not a therapy for AKI

Drugs Implicated in Prerenal Azotemia
Diuretics
NSAIDs
ACEI/ARBs

Treatment

1. preliminary measures
   - prerenal
     - correct prerenal factors: optimize volume status and cardiac performance using fluids that will stay in the plasma subcompartment (NS, albumin, blood/plasma), hold ACEI/ARB (gently rehydrate when needed, e.g. CHF), and NSAIDs
   - renal
     - address reversible renal causes: discontinue nephrotoxic drugs, treat infection, and optimize electrolytes
     - correct ECF volume, supportive care
   - postrenal
     - consider obstruction: structural (stones, strictures) vs. functional (neuropathy)
     - for obstruction to cause AKI, must have functional solitary kidney or obstruction affecting both kidneys
     - treat with Foley catheter insertion, indwelling bladder catheter, nephrostomy, stenting
2. treat complications
   - fluid overload
     - NaCl restriction
     - high dose loop diuretics
   - electrolyte imbalances (hyperkalemia, hyperphosphatemia, hypocalcemia, hypo/hypermagnesemia, hyperuricemia)
   - acid–base disturbances
   - adjust dosages of medications cleared by kidney (e.g. amiodarone, digoxin, cyclosporine, tacrolimus, some antibiotics, and chemotherapeutic agents)
   - dialysis
3. definitive therapy depends on etiology (e.g. corticosteroids for AIN or immunosuppression for GN)

Timing of Initiation of Renal Replacement Therapy in Acute Kidney Injury
NEJM 2020;383:240-51
Purpose: Elucidate the most effective timing for initiation of renal-replacement therapy in patients with AKI who are critically ill.
Methods Multinational RCT involving critically ill patients with AKI. Patients were randomly assigned to receive an accelerated regimen of renal-replacement therapy (initiated within 12 h after eligibility criteria were met) or a standard strategy (in which renal-replacement therapy was discouraged unless indications developed or AKI >72 h). The primary outcome was all-cause mortality at 90 d.
Results 2927 of the 3019 randomized patients were included in the final intention-to-treat analysis. The 90-day mortality was 43.9% in the accelerated group and 43.7% in the standard strategy group (RR 1.00; 95%CI 0.93 to 2.09, P=0.92). Among 90-day survivors, continued reliance on renal-replacement therapy was 10.4% in the accelerated group and 6.0% in the standard group (RR 1.74; 95% CI 1.24 to 2.43). Adverse events occurred at 23.0% in the accelerated group and 16.5% in the standard group (P<0.001).
Conclusion: Among critically ill patients with acute kidney injury, an accelerated renal-replacement strategy was not associated with lower mortality risk than standard strategy at 90 d.

Prognosis

- high morbidity and mortality in patients with sustained AKI and multi-organ failure

Parenchymal Kidney Diseases

Glomerular Diseases

HISTOLOGICAL TERMS OF GLOMERULAR CHANGES

Extent of Changes

- histological terms describing the number of glomeruli affected in a given condition:
  - diffuse: majority of glomeruli abnormal
  - focal: some glomeruli abnormal
- histological terms describing the extent to which individual glomeruli are affected in a given condition
  - global: entire glomerulus abnormal
  - segmental: only part of the glomerulus abnormal

Types of Changes

- proliferation: hyperplasia of one of the glomerular cell types (mesangial, endothelial, parietal epithelial), with or without inflammatory cell infiltration
- crescent formation: parietal epithelial cell proliferation (Bowman's capsule lining) and mononuclear cell infiltration form crescent-shape in Bowman's space (hallmark of inflammatory glomerulonephritis)
- membranous changes: capillary wall thickening due to immune deposits or alterations in basement membrane
- podocytopathy: podocyte (visceral epithelial layer) injury leading to effacement of the foot-processes that wrap around the basement membrane forming part of the filtration barrier.

CLINICAL FEATURES OF GLOMERULAR DISEASE

Important Points to Remember

- glomerular diseases have diverse clinical features including hematuria, proteinuria, HTN, edema, and decreased GFR
  - glomerular injuries may manifest as distinct syndromes depending on the pattern and extent of injury
    1. asymptomatic urinary abnormalities
       - isolated subnephrotic proteinuria
       - isolated hematuria
    2. nephritic syndrome
       - acute GN
       - rapidly progressive GN

3. nephrotic syndrome
4. ESRD

- glomerulopathies can be caused by a primary disease or can occur secondary to a systemic disease
- some glomerulopathies can present as more than one syndrome at different times

The Nephritic-Nephrotic Spectrum

- glomerular pathology can present with a clinical picture anywhere on a spectrum with pure nephritic (inflammation of glomeruli) and pure nephrotic syndromes (abnormal glomerular permeability) at the extremes

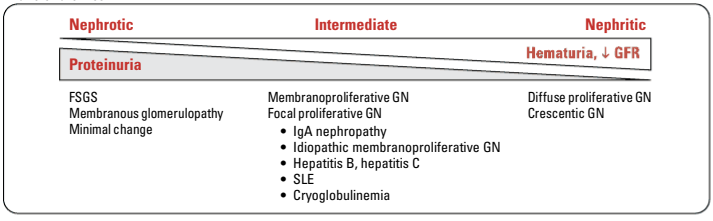

Figure 13. Spectrum of glomerular pathology

Proteinuria

- hallmark of nephrotic syndromes
- composition of normal urine protein: albumin, lower molecular proteins (such as immunoglobulin light chain), or proteins secreted by the tubular epithelial cells (e.g. Tamm-Horsfall mucoprotein)
- 24 h urine protein: gold standard to assess degree of proteinuria
  - upper limit of normal daily excretion of total protein is 150 mg/d
  - upper limit of normal daily excretion of albumin is 30 mg/d, albuminuria that persists for >3 mo is considered CKD
- spot/random urine ACR: used to screen for diabetic nephropathy and proteinuric renal disease
- microalbuminuria: ACR ≥2.0 mg/mmol
  - marker of vascular endothelial function
  - an important prognostic marker for CKD (see *Diabetes Insipidus, NP12*)
  - microalbuminuria is the earliest sign of diabetic nephropathy

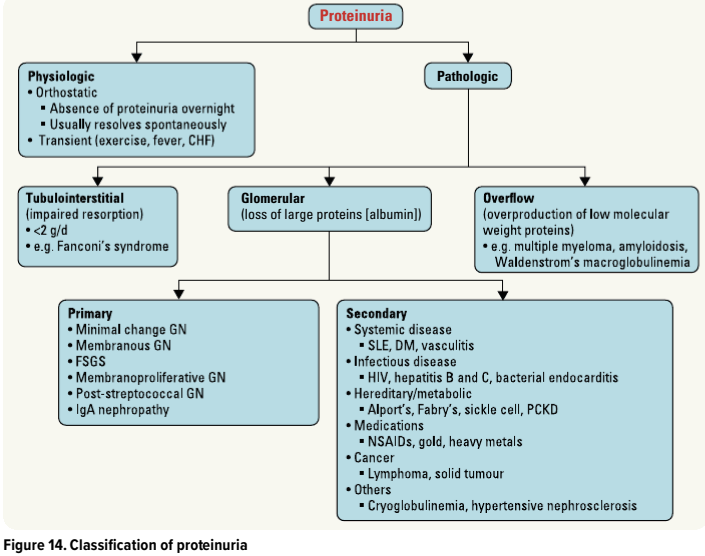

Figure 14. Classification of proteinuria

Pathologic Proteinuria

Tubulointerstitial

Normally low molecular weight proteins (<60 kDa) pass through glomerular filtration barrier and are reabsorbed in proximal tubule

Proximal tubule dysfunction causes impaired reabsorption and increased excretion of low molecular weight proteins

Albumin (>60 kDa) is not affected; thus, edema is partly secondary to salt and water retention

Glomerular

Normally, the filtration barrier is selectively permeable to size (<60 kDa) and charge (repels negative particles); thus, albumin is filtered to a very limited extent through a normal glomerulus

Damage to any component of the glomerular filtration barrier results in loss of albumin and other high molecular weight proteins; thus, edema is secondary to hypoalbuminemia (low oncotic pressure), but also due to enhanced renal tubular reabsorption of filtered sodium and water (possibly due to filtered proteins stimulating the action of cortical collecting duct epithelial sodium channel)

Overflow

Increased production of low molecular weight proteins which exceeds the reabsorptive capacity of the proximal tubule

Plasma cell dyscrasias produce light chain Ig (multiple myeloma, Waldenstrom's macroglobulinemia, monoclonal gammopathy of renal significance)

Table 11. Daily Excretion of Protein

Daily Excretion	Stage of Nephropathy	ACR	PCR
<150 mg total protein (and <30 mg albumin)	Normal	<2.0 mg/mmol	<15 mg/mmol
30-300 mg albumin	Microalbuminuria	>2.0 mg/mmol	
>3500 mg total protein/1.73 m ^{2}body surface area	Nephrotic range proteinuria	>220 mg/mmol	>300 mg/mmol
Variable amount of proteinuria	Can be seen with glomerular disease		
Up to 2000 mg per d	Possible tubular disease because of failure to reabsorb filtered proteins		

Investigations
- urea, creatinine, ACR, PCR
- urine R&M, C&S, urine dipstick
- further workup (if degree of proteinuria >0.5 g/d, casts, and/or hematuria)
  - CBC, glucose, electrolytes, 24 h urine protein and albumin, and Cr
  - urine and serum immunoelectrophoresis, abdominal/pelvic U/S
  - serology: ANA, RF, p-ANCA (MPO), c-ANCA (PR3), C3, C4, HBV, HCV, HIV, ASOT
- consider urology consult and possible cystoscopy if not clearly a nephrologic source for hematuria or if >50 yr of age

Glomerular Syndromes

1. ASYMPTOMATIC URINARY ABNORMALITIES

Clinical/Lab Features
- often have rapid decline in GFR, anemia, elevated inflammatory markers, ECF volume replete, or mildly overloaded
- proteinuria (usually <2 g/d) and/or microscopic or macroscopic hematuria
  - isolated proteinuria
    - can be postural
    - occasionally can signal beginning of more serious GN (e.g. FSGS, IgA nephropathy, amyloid, diabetic nephropathy)
  - hematuria with or without proteinuria
    - IgA nephropathy (Berger's disease): most common type of primary glomerular disease worldwide, frequently presents after viral upper respiratory tract infection (presents most frequently with gross hematuria)
      - more common in White and Asian populations, and in the 2nd and 3rd decades of life
      - may be associated with cirrhosis, HIV infection, celiac disease
      - mesangial deposition of IgA (more dominant) and C3 seen on immunofluorescence microscopy
      - potential treatment includes: RAAS blockers if proteinuria, steroids, and steroid sparing agents (azathioprine, cyclophosphamide, mycophenolate mofetil, and biologics such as rituximab)
    - hereditary nephritis (Alport Syndrome; Type IV collagen mutation): X-linked nephritis often associated with sensorineural hearing loss; proteinuria <2 g/d
    - thin basement membrane disease: usually autosomal dominant, without proteinuria; benign
    - benign recurrent hematuria: hematuria associated with febrile illness, exercise, or immunization; a diagnosis of exclusion after other possibilities are ruled out

2. NEPHRITIC SYNDROME

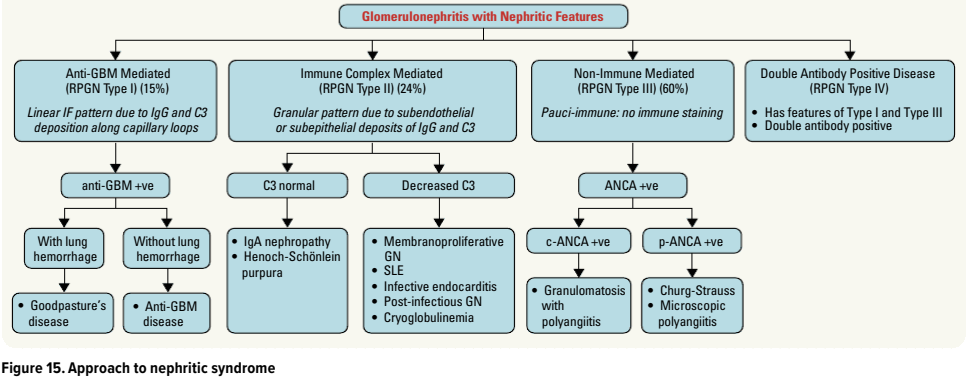

Figure 15. Approach to nephritic syndrome

Rapidly progressive GN
- a subset of nephritic syndrome in which the clinical course occurs over days
- etiology can be divided into low and normal complement levels
- frequently immune-mediated, with Ig and C3 deposits found in GBM; but may be pauci-immune and caused by an ANCA vasculitis
- nephritic syndromes usually denote proliferative glomerulonephritis.
- clinical and histopathological syndrome (e.g. (glomerular crescents on biopsy)
- any type of proliferative GN can present as RPGN
- additional etiologies seen only as RPGN: anti-GBM disease and granulomatosis with polyangiitis (GPA) (previously called Wegener's granulomatosis)
- glomerular crescents crescentic GN (identified by pathology) is frequently seen in RPGN resulting from proliferation of parietal epithelial cells and is the most aggressive form of glomerular disease

Clinical/Lab Features
- Triad of:
  - hematuria (microscopic or macroscopic), RBC casts and/or dysmorphic RBCs in urine
  - azotemia (increased Cr and urea)
  - HTN (due to salt and water retention)
- proteinuria (less than range for nephrotic syndrome, <3.5 g/1.73 m ^{2}/d)
- may have peripheral edema/puffy eyes

Treatment
- depends on etiology
- pulse steroid therapy and other immunosuppression (steroid sparing agents such as azathioprine and cyclophosphamide, mycophenolate mofetil, and biologics such as rituximab), BP control (with RAAS agents), plasma exchange, monitoring for progression to ESRD

Clinical Features
- insidious onset presenting with fatigue or edema
- oliguria (not commonly)
- hypertension

Investigations
- fibrous crescents typically present on renal histopathology
- RBC casts and/or dysmorphic RBCs in urine
- classified by immunofluorescence staining
- Type I: anti-GBM mediated (15% of cases)
- Type II: immune complex mediated (24% of cases)
- Type III: Pauci-immune (ANCA associated vasculitis) (60% of cases)
- Type IV: double antibody positive (anti-GBM and ANCA)

Treatment and Prognosis
- treatment: underlying cause if post-infectious; corticosteroids and cyclophosphamide or other cytotoxic agent and plasmapheresis to manage cases such as anti-GBM disease
- prognosis: 50% recovery with early treatment, depends on underlying cause

3. NEPHROTIC SYNDROME

Definition
- distinct constellation of clinical and laboratory features of renal disease defined by the presence of heavy proteinuria (protein excretion greater than 3.5 g/24 h), hypoalbuminemia (less than 3 g/dL), peripheral edema, and hyperlipidemia

Clinical/Lab Features
- heavy proteinuria (>3.5 g/1.73 m ^{2}/d)
- hypoalbuminemia
- edema
- hyperlipidemia (elevated LDL cholesterol due to increased liver albumin production), lipiduria (fatty casts and oval fat bodies on microscopy)
- hypercoagulable state (due to antithrombin III, Protein C, and Protein S urinary losses)
- patient may report frothy urine
- glomerular pathology on renal biopsy
- minimal change disease (or minimal lesion disease or nil disease): e.g. glomeruli appear normal on light microscopy
  - membranous glomerulopathy
  - FSGS
  - membranoproliferative GN
  - nodular glomerulosclerosis
- each can be idiopathic or secondary to a systemic disease or drug (Interferon, NSAIDs, Penicillamine)

Interventions for Renal Vasculitis in Adults
Cochrane DB Syst Rev 2015; CD003232
Purpose: To assess benefits and harms of any intervention used for the treatment of renal vasculitis in adults.
Methods: RCTs in Cochrane Kidney and Transplant Specialized Register investigating any intervention for the treatment of renal vasculitis in adults.
Conclusions: Plasma exchange was effective in patients with severe AKI secondary to vasculitis. Pulse cyclophosphamide resulted in an increased risk of relapse (compared to continuous oral) but required reduced dose. Rituximab and mycophenolate mofetil were comparable in efficacy to cyclophosphamide. Azathioprine, methotrexate and leflunomide were effective as maintenance therapy.

See Landmark Nephrology Trials table for more information on BLISS-LN which details the efficacy and safety of IV belimumab as an add-on therapy in the management of lupus nephritis.

ALMS trial is a classic LN trial that showed benefit for MMF in LN

Table 12. Nephrotic Syndrome

	Minimal Change	Membranous Glomerulopathy	Focal Segmental Glomerulosclerosis	Membranoproliferative Glomerulonephritis	Nodular Glomerulosclerosis
Secondary Causes	Hodgkin's Lymphoma (primarily) and Non-Hodgkin Lymphoma	HBV, SLE, solid tumours (lung, breast, GI)	Reflux nephropathy, HIV, HBV, obesity, sickle cell disease	HCV, malaria, SLE, leukemia, lymphoma, shunt nephritis	DM, amyloidosis
Drug Causes	NSAIDs	Gold, penicillamine	Heroin		
Therapy	Steroids	Reduce BP, ACEI, steroids, Rituximab, cytotoxic agents (cyclophosph amide), calcineurin inhibitors	Steroids, cytotoxic agents (cyclophosphamide), immunosuppressive agents (calcineurin inhibitors, cyclosporine), ACEI/ARB for proteinuria	Aspirin®, ACEI, dipyridamole (Persantine®) – controversial	Treat underlying cause

Note: the most common secondary causes are diabetes mellitus and amyloidosis

4. END STAGE RENAL DISEASE

- see *End Stage Renal Disease, NP40*

Investigations for Glomerular Disease

- blood work
  - first presentation: electrolytes, CBC, Cr, urea, albumin, fasting lipids, ACR
  - determining etiology: ESR, serum immunoelectrophoresis (for amyloidosis or multiple myeloma), C3, C4, ANA, p-ANCA, c-ANCA, cryoglobulins, HBV and HCV serology, ASOT, VDRL, HIV, anti-GBM antibodies, serum free light chain assay, urine protein electrophoresis
- urinalysis: RBCs, WBCs, casts, protein
- 24 h urine for protein and CrCl
- radiology
  - CXR (infiltrates, CHF, pleural effusion)
  - renal U/S: with renal dopplers to rule out renal vein thrombosis
  - for Bence-Jones protein if proteinuria present
- renal pathology (light microscopy, immunofluorescence, electron microscope

SECONDARY CAUSES OF GLOMERULAR DISEASE

Amyloidosis

- nodular deposits of amyloid in mesangium, usually related to amyloid light chain (AL)
- presents as nephrotic range proteinuria (albuminuria) with progressive renal insufficiency
- can be primary or secondary to multiple myeloma, TB, Inflammatory diseases (e.g. rheumatoid arthritis), or malignancy

Systemic Lupus Erythematosus

- see Rheumatology, RH11
- lupus nephritis can present as any of the glomerular syndromes
- nephrotic syndrome with an active sediment is most common presentation
- GN caused by immune complex deposition in capillary loops and mesangium with resulting renal injury
- serum complements (C3 and C4),levels are usually low during periods of active renal disease, Anti-dsDNA levels are high
- children and males with SLE are more likely to develop

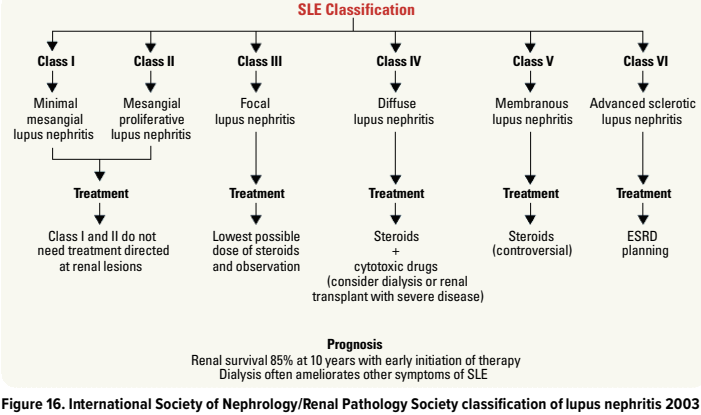

Figure 16. International Society of Nephrology/Renal Pathology Society classification of lupus nephritis 2003

EULAR Recommendations for the Management of Systemic Lupus Erythematosus (SLE)
Ann Rheum Dis 2008;67:195-205
Lupus Nephritis Recommendations
Monitoring: Renal biopsy, urine sediment analysis, proteinuria, and kidney function may have independent predictive ability for clinical outcome in therapy of lupus nephritis but need to be interpreted in conjunction. Changes in immunological tests (anti-dsDNA, serum C3) have limited ability to predict response to treatment and may be used only as supplemental information.
Treatment: In patients with proliferative lupus nephritis, glucocorticoids in combination with immunosuppressive agents are effective against progression to end-stage renal disease. Long-term efficacy has been demonstrated only for cyclophosphamide-based regimens, which are associated with considerable adverse effects. In short- and medium-term trials, mycophenolate mofetil has demonstrated at least similar efficacy compared with pulse cyclophosphamide and has a more favourable toxicity profile. If failure to respond by 6 mo consider intensifying therapy. Flares following remission are not uncommon and require diligent follow-up.
End-Stage Renal Disease: Dialysis and transplantation in SLE have long-term patient and graft-survival rates comparable with those observed in non-diabetic non-SLE patients. Transplantation is the method of choice.

IgA Vasculitis (Henoch-Schönlein Purpura)
- systemic IgA vasculitis, tissue deposition of IgA1-dominant immune complexes affecting mostly small vessels
- seen more commonly in children
- purpura on buttocks and legs, abdominal pain, arthralgia, and fever
- IgA and C3 staining of mesangium
- usually benign, self-limiting course, 10% progress to CKD

ANCA-Associated Vasculitis
- multi system or renal limited disease
- c-ANCA (anti-Proteinase 3 (PR3)) most commonly associated with the clinical picture of granulomatosis with polyangiitis
- p-ANCA (anti-Myeloperoxidase (MPO)) most commonly associated with the clinical picture of microscopic polyangiitis
- focal segmental necrotizing RPGN (crescents) with no immune staining
- may be indolent or fulminant in progression
- vasculitis and granulomas rarely seen on renal biopsy
- treatment typically involves Steroids and cyclophosphamide/Rituximab
- plasmapheresis is indicated in severe renal disease and/ or pulmonary hemmorhage.

Cryoglobulinemic Vasculitis
- cryoglobulins: monoclonal IgM (Type I) and polyclonal IgG (Type II and Type III)which precipitate at reduced temperatures, deposit in walls of small vessels
- presents as purpura, fever, Raynaud's phenomenon, and arthralgias, AKI
- at least 50% of patients have HCV
- renal disease seen in 40% of patients (isolated proteinuria/hematuria progressing to nephritic syndrome)
- most patients have decreased serum complement (C4 initially)
- treatment: antiviral therapy for HCV, plasmapheresis, steroids, cyclophosphamide, myeloma therapy
- overall prognosis: 75% renal recovery

Shunt Nephritis
- immune-complex mediated nephritis associated with chronically infected ventriculoatrial shunts inserted for treatment of hydrocephalus
- commonly caused by *S. epidermidis*
- presents as acute nephritic syndrome with decreased serum complement
- nephrotic range proteinuria in 25% of patients
- treat by removing shunt and administering appropriate antibiotics; can consider a ventriculoperitoneal shunt

HIV-Associated Renal Disease
1. direct nephrotoxic effect of HIV infection, anti-retroviral drugs (e.g. tenofovir, indinavir), and other drugs used to treat HIV-associated infections
2. HIV-associated nephropathy

- histology: focal and segmental glomerular collapse with mesangial sclerosis; "collapsing FSGS"
  - tubular cystic dilation and tubulo-reticular inclusions
  - clinical features: predominant in African American men, heavy proteinuria, progressive renal insufficiency (Apo-L-1 risk genotypes)
  - prognosis: kidney failure within 1 yr without treatment
  - therapy: short-term, high dose steroids, ACEI, HAART

Infective Endocarditis
- manifests as mild form of acute nephritic syndrome with decreased serum complement
- *S. aureus* is most common infecting agent
- treatment with appropriate antibiotics usually resolves GN

Hepatitis B
- can result in membranous nephropathy, membranoproliferative GN, and polyarteritis nodosa

Hepatitis C
- can result in membranous nephropathy, membranoproliferative GN, and cryoglobulinemia

Syphilis
- can result in membranous GN

Tubulointerstitial Disease

TUBULOINTERSTITIAL NEPHRITIS

Definition
- cellular infiltrates affecting primarily the renal interstitium and tubular cells
- functional tubule defects are disproportionately greater than the decrease in GFR
- classified as acute or chronic

Signs and Symptoms
- manifestation of disease depends on site of tubule affected
  1. proximal tubule (e.g. multiple myeloma, heavy metals, genetic diseases such as Dent's disease or Lowes disease)
     - Fanconi syndrome: decreased reabsorption in proximal tubule causing glycosuria, aminoaciduria, phosphaturia, and hyperuricosuria
     - proximal RTA (decreased bicarbonate absorption): Type II RTA
  2. distal tubule (e.g. amyloidosis, obstruction)
     - distal RTA (decreased hydrogen secretion, usually hypokalemic): Type I RTA
     - Na $^{+}$-wasting nephropathy
     - ± hyperkalemia leading to Type IV RTA (where reduced renal bicarbonate production is caused by hyperkalemia)
  3. collecting duct (e.g. sickle cell anemia, analgesics, primary ciliary dyskinesia)
     - urinary concentrating defect leading to mild nephrogenic DI
     - polyuria

IgA nephropathy is the most common type of primary glomerular disease worldwide

Features of Nephritic Syndrome

PHAROH
Proteinuria
Hematuria
Azotemia
RBC casts
Oliguria
HTN

Presentation of Nephrotic Syndrome

HELP
Hypoalbuminemia
Edema
Lipid abnormalities
Proteinuria

1. ACUTE TUBULOINTERSTITIAL NEPHRITIS

Definition
- rapid (days to weeks) decline in renal function
- 10-20% of all AKI

Etiology
- hypersensitivity
  1. antibiotics: β-lactams, sulfonamides, rifampin, quinolones, cephalosporins
  2. other: NSAIDs, allopurinol, furosemide, thiazides, triamterene, PPIs, acyclovir, phenytoin, cimetidine
- infections
  - bacterial pyelonephritis, *Streptococcus*, brucellosis, *Legionella*, CMV, EBV, toxoplasmosis, leptospirosis, HIV, *Mycoplasma*
- immune
  - SLE, acute allograft rejection, Sjögren's syndrome, sarcoidosis, mixed essential cryoglobulinemia (Type III)
- idiopathic (renal-ocular syndrome – acute TIN plus uveitis)

Pathophysiology
- acute inflammatory cell infiltrates into renal interstitium

Clinical Features
- AKI
- if hypersensitivity reaction (common with antibiotics): may see fever, eosinophilia, skin rash, arthralgia, serum sickness-like syndrome (particularly rifampin)
- if pyelonephritis: flank pain and costovertebral angle tenderness
- if drug reaction, AKI usually occurs 7-10 d after exposure
- other signs and symptoms based on underlying etiology
- HTN and edema are uncommon

Findings
- urine
  - mild, non-nephrotic range proteinuria and microscopic hematuria
  - sterile pyuria, WBC casts
  - eosinophils if AIN
- blood work
  - increased Cr and urea
  - eosinophilia if drug reaction (high negative predictive value, common in β-lactam reactions)
  - normal AG metabolic acidosis (RTA)
  - hypophosphatemia, hypo- OR hyperkalemia, hyponatremia
- gallium scan often shows intense signal due to inflammatory infiltrate
- renal biopsy definitive – shows interstitial infiltrates and edema on biopsy

Treatment
- treat underlying cause (e.g. stop offending medications, treat infection with antibiotics if present i.e. pyelonephritis)
- corticosteroids (may be indicated in allergic or immune disease)

Prognosis
- recovery within 2 wk if underlying insult can be eliminated
- the longer the patient is in renal failure, the less likely they will have a full renal recovery

2. CHRONIC TUBULOINTERSTITIAL NEPHRITIS

Definition
- characterized by slowly progressive renal failure, moderate proteinuria, and signs of abnormal tubule function

Etiology
- persistence or progression of acute TIN
  - may also involve concurrent glomerular manifestations
- urinary tract obstruction: most important cause of chronic TIN (tumours, stones, bladder outlet obstruction, vesicoureteral reflux)
- chronic pyelonephritis due to vesicoureteral reflux or UTI with obstruction
- nephrotoxins
  - exogenous
    - analgesics: NSAIDs (common), acetaminophen
    - cisplatin, lithium, cyclosporine, tacrolimus
    - heavy metals (lead, cadmium, copper, lithium, mercury, arsenic)
    - Chinese herbs (aristolochic acid)
  - endogenous
    - hypercalcemia, hypokalemia, oxalate, uric acid
- vascular disease: ischemic nephrosclerosis, atheroembolic disease
- malignancies: multiple myeloma, lymphoma
- granulomatous: TB, sarcoidosis, granulomatosis with polyangiitis, inflammatory bowel disease
- immune: SLE, Sjögren's, cryoglobulinemia, anti-GBM disease, amyloidosis, renal graft rejection, vasculitis
- hereditary: cystic diseases of the kidney, sickle cell disease
- others: radiation, Balkan (endemic) nephropathy

Pathophysiology
- fibrosis of interstitium with atrophy of tubules, mononuclear cell inflammation

Signs and Symptoms
- dependent on underlying etiology

Findings
- non-AG metabolic acidosis
- hyperkalemia (out of proportion to degree of renal insufficiency)
- polyuria, nocturia
- partial or complete Fanconi's syndrome
- progressive renal failure with azotemia and uremia
- urine: mild proteinuria, few RBCs and WBCs, no RBC casts
- U/S: shrunken kidneys with irregular contours (differentiates acute from chronic etiology)

Treatment
- stop offending agent or treat underlying disease
- supportive measures: correct metabolic disorders (Ca^{2+}, PO_4^{3-}) and anemia

3. ACUTE TUBULAR NECROSIS

Definition
- abrupt and sustained decline in GFR within minutes to days after ischemic/nephrotoxic insult
- GFR reduced (this serves the purpose of avoiding life-threatening urinary loss of fluid and electrolytes from non-functioning tubules)

Effectiveness of Prevention Strategies for Contrast-Induced Nephropathy: A Systematic Review and Meta-Analysis
Ann Intern Med 2016;164(6):406-416
Purpose: To evaluate the comparative effectiveness of interventions to reduce contrast-induced nephropathy in adults receiving contrast media.
Methods: Meta-analysis of RCTs N-acetylcysteine, sodium bicarbonate, statins, or ascorbic acid that used IV or intra-arterial contrast media.
Results: Low dose N-acetylcysteine+IV saline vs. IV saline (RR 0.75, 95% CI 0.63-0.89). N-acetylcysteine+IV saline vs. IV saline (RR 0.69, 95% CI 0.58-0.84). Statins+N-acetylcysteine+IV saline vs. N-acetylcysteine+IV saline (RR 0.52, 95% CI 0.29-0.93). Clinically important, but not statistically significant, reductions were observed in sodium bicarbonate vs. IV saline, statins+IV saline vs. IV saline, and ascorbic acid vs. IV saline.
Conclusions: Greatest reduction in contrast-induced nephropathy was seen with N-acetylcysteine plus IV saline and statins plus N-acetylcysteine plus IV saline.

Etiology

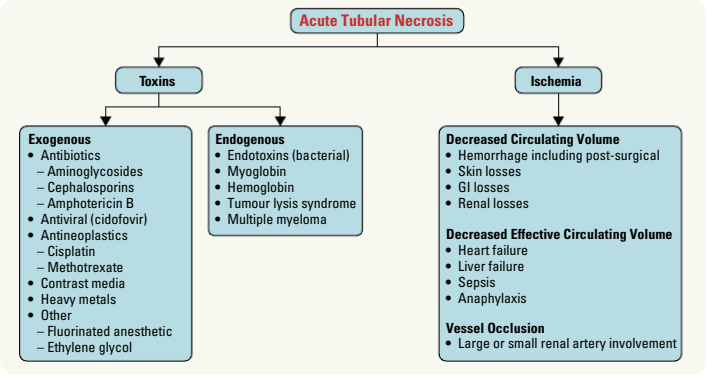

Figure 17. Etiology of ATN

Clinical Features

- typically presents as an abrupt rise in urea and Cr after a hypotensive episode, sepsis, rhabdomyolysis, or administration of nephrotoxic drug
  - pre-renal AKI can eventually progress to ATN
  - consists of three phases:
    - oliguric: decreased urinary output from renal damage, azotemia, and uremia; lasts 10-14 d
    - diuretic: urinary output >500 mL/day (result of retained water, salt, and solutes during oliguric phase) and tubular cell damage
    - recovery: tubular function recovers
- physical exam may show signs of true or effective ECF volume depletion
- most common cause of non-prerenal AKI in hospitalized patients
- urine: high FE_{Na} (>2%), pigmented-granular casts

Risk Factors

- pre-existing CKD, pre-existing cardiovascular disease, ECF volume depletion, multiple renal insults

Complications

- hyperkalemia: can occur rapidly and cause serious arrhythmias
- metabolic acidosis, decreased Ca^{2+}, increased PO_4^{3-}, hypoalbuminemia

Investigations

- blood work: CBC, electrolytes, Cr, urea, Ca^{2+}, PO_4^{3-}, blood gasses
- urine: R&M, electrolytes, osmolality, microscopic urinalysis searching for heme granular/muddy brown casts
- ECG (monitor for arrhythmias due to hyperkalemia)
- abdominal U/S
- rule out other causes of prerenal/postrenal azotemia and intrinsic AKI (GN, AIN, vasculitis)
  - IV fluid challenge will not increase urine output or normalize serum creatinine in ATN, helps to differentiate ATN from pre-renal AKI
  - if diagnosis is uncertain, biopsy

Treatment

- largely supportive once underlying problem is corrected
- dialysis if indicated (refractory volume overload, metabolic acidosis, hyperkalemia, uremic encephalopathy or pericarditis)
- no benefit found for early start dialysis in critically ill patients

Prevention

- correct fluid balance before surgical procedures
- for patients with chronic renal disease requiring radiographic contrast:
  - isotonic saline
  - avoid giving diuretics, NSAIDS, ACEI, cyclosporine on morning of procedure if possible
- use renal-adjusted doses of nephrotoxic drugs in patients with renal insufficiency
- use low dose non-ionic, iso- or low-osmolal contrast agents

Vascular Diseases of the Kidney

LARGE VESSEL DISEASE

Table 13. Summary of Vascular Diseases

Large Vessel Disease	Medium Vessel Disease	Small Vessel Disease
Acute renal artery occlusion (infarct)	Kawasaki disease	Hypertensive nephrosclerosis
Renal artery stenosis (ischemia)	Polyarteritis nodosa	Atheroembolic renal disease
Renal vein thrombosis	ANCA-associated vasculitis	Thrombotic microangiopathy
		Scleroderma
		Calcineurin inhibitor nephropathy
		HUS
		ANCA-associated vasculitis

1. RENAL INFARCTION (ACUTE RENAL ARTERY OCCLUSION)

- important, potentially reversible cause of renal failure

Etiology

- abdominal trauma, surgery, embolism, vasculitis, extrarenal compression, hypercoagulable state, aortic dissection
- kidney transplant recipients more vulnerable

Signs and Symptoms (depend on presence of collateral circulation)

- fever, N/V, flank pain
- leukocytosis, elevated AST, ALP
- marked elevated LDH (LDH >4x upper limit of normal with minimal elevations in AST/ALT strongly suggestive)
- acute onset HTN (activation of RAAS) or sudden worsening of long-standing HTN
- renal dysfunction, e.g. elevated Cr (if bilateral, or solitary functioning kidney)

Investigations

- renal arteriography (more reliable but risk of atheroembolic renal disease)
- contrast-enhanced CT or MR angiography, duplex Doppler studies (operator dependent)

Treatment

- prompt localization of occlusion and restoration of blood flow
- anticoagulation, thrombolysis, percutaneous angioplasty or clot extraction, surgical thrombectomy
- medical therapy in the long-term to reduce risk (e.g. antihypertensives)

2. ISCHEMIC RENAL DISEASE (RENAL ARTERY STENOSIS)

- chronic renal impairment secondary to hemodynamically significant renal artery stenosis or microvascular disease
- significant cause of ESRD: 15% in patients >50 yr (higher prevalence if significant vascular disease)
- usually associated with large vessel disease elsewhere
- causes of renal artery stenosis
  - atherosclerotic plaques (90%): proximal 1/3 renal artery, usually males >55 yr, smokers
  - fibromuscular dysplasia (10%): distal 2/3 renal artery or segmental branches, usually young females (typical onset <30 yr)
- when there is decreased RBF, GFR is dependent on angiotensin II-induced efferent arteriolar constriction which raises the FF (GFR/RBF)
- most common cause of secondary HTN ("renovascular HTN"), 1-2% of all hypertensive patients
  - etiology
    - decreased renal perfusion of one or both kidneys leads to increased renin release and subsequent angiotensin production
    - increased angiotensin raises blood pressure in two ways
    1. causes generalized arteriolar constriction
    2. release of aldosterone increases Na^+ and water retention
      - elevated blood pressure can in turn lead to further damage of kidneys and worsening HTN

Risk Factors

- age >50 yr
- smoking
- other atherosclerotic disease (dyslipidemia, DM, diffuse atherosclerosis)

Signs and Symptoms

- severe/refractory HTN and/or hypertensive crises, with negative family history of HTN
- asymmetric renal size
- epigastric or flank bruits
- spontaneous hypokalemia (renin activation in under-perfused kidney)
- increasing Cr with ACEI/ARB
- flash pulmonary edema with normal LV function

Treatment of Hypertension in Association with Renovascular Disease
Can J Cardiol 2017;33(5):557-576
Guidelines:
1. Recommend medical management as renal angioplasty and stenting offers no benefit over optimal medical therapy alone
2. In patients with uncontrolled HTN resistant to maximally tolerated pharmacotherapy, progressive renal function loss and acute pulmonary edema, renal artery angioplasty and stenting for atherosclerotic hemodynamically significant stenosis could be considered
3. Patients with confirmed renal fibromuscular dysplasia should be referred to HTN specialist and considered for revascularization

Investigations
- must establish presence of renal artery stenosis and prove it is responsible for renal dysfunction
- duplex Doppler U/S (kidney size, blood flow): good screening test (operator dependent)
- digital subtraction angiography (risk of contrast nephropathy)
- CT or MR angiography (effective noninvasive tests to establish presence of stenosis, for MR avoid gadolinium contrast if eGFR <30 mL/min because of risk of systemic dermal fibrosis)
- ACEI renography (e.g. captopril renal scan)
- renal arteriography (gold standard, but risk of contrast nephropathy)

Treatment
- treatment of renal artery stenosis is performed for select cases of blood pressure control, treatment of heart failure, pulmonary edema, and prevention of nephropathy
- medical therapy includes potential use of ACEI, statins, and platelet inhibitors
- revascularization using stenting is performed to treat or prevent development of ischemic nephropathy, although there is debate surrounding its efficacy
- surgical bypass or reconstruction is an option but benefit over angioplasty is debated

Stenting and Medical Therapy for Atherosclerotic Renal Artery Stenosis
NEJM 2014;370:13-22
Study: Multicentre, unblinded RCT, median follow-up of 43 mo.
Patients: 947 patients with atherosclerotic renal-artery stenosis who also have significant systolic HTN or CKD.
Intervention: 947 patients with atherosclerotic renal-artery stenosis who also have significant systolic HTN or CKD.
Intervention: Percutaneous revascularization (stenting) with medical therapy (statins, ARB, calcium channel blockers, HCTZ, and BP control) vs. medical therapy alone.
Outcomes: Occurrence of adverse CV or renal event (composite of death from CV or renal cause, MI, stroke, hospitalization for CHF, progressive renal insufficiency, or need for renal replacement therapy) and all-cause mortality.
Outcomes: Occurrence of adverse CV or renal event (composite of death from CV or renal cause, MI, stroke, hospitalization for CHF, progressive renal insufficiency, or need for renal replacement therapy) and all-cause mortality.
Results: No significant difference in primary composite endpoint between participants who received stenting or those on medical therapy alone. No significant differences between the treatment groups in the rates of the individual components of the primary endpoint or in all-cause mortality..
Conclusion: Renal artery stenting did not confer a significant benefit with respect to the prevention of clinical events when added to comprehensive, multifactorial medical therapy in people with atherosclerotic renal artery stenosis and HTN or CKD.

3. RENAL VEIN THROMBOSIS

Etiology
- endothelial damage: blunt trauma, tumour infiltration (e.g. RCC), vasculitis, renal transplant, and acute rejection
- stasis: severe volume loss (i.e. GI fluid loss, hemorrhage, dehydration), renal vein compression
- hypercoagulability: nephrotic syndrome, sepsis, oral contraceptives, disseminated malignancy, intrinsic hypercoagulability, sickle cell disease
- hypercoagulable states (e.g. nephrotic syndrome, especially membranous), ECF volume depletion, extrinsic compression of renal vein, significant trauma, malignancy (e.g. RCC), sickle cell disease
- clinical features determined by rapidity of occlusion and formation of collateral circulation

Signs and Symptoms
- acute: N/V, flank pain, hematuria, elevated plasma LDH, ± rise in Cr, sudden rise in proteinuria
- chronic: PE (typical first presenting symptom), increasing proteinuria, and/or tubule dysfunction

Investigations
- renal venography (gold standard), CT or MR angiography, duplex Doppler U/S

Treatment
- anticoagulation therapy to aid in recanalisation, improve renal function, and reduce risk of thromboembolism. Initial treatment using IV heparin, followed by warfarin (target INR 2.5) within 3-10 d continued for minimum 1 yr
- certain cases are suitable for thrombectomy or thrombolysis (local or systemic). Commonly used agents include streptokinase, urokinase, and tissue plasminogen activators

MEDIUM VESSEL DISEASE

1. KAWASAKI DISEASE
- see Pediatrics, P99

2. POLYARTERITIS NODOSA
- see Rheumatology, RH21
- kidneys most commonly involved organ
- heterogenous impact on renal function
- pathologically can cause glomerular ischemia which manifests as mild proteinuria and hypertension

SMALL VESSEL DISEASE

1. HYPERTENSIVE NEPHROSCLEROSIS
- see *Hypertension, NP38*

2. ATHEROEMBOLIC RENAL DISEASE
- progressive renal insufficiency due to embolic obstruction of small- and medium-sized renal vessels by atheromatous emboli
- spontaneous or after renal artery manipulation (surgery, angiography, percutaneous angioplasty)
- anticoagulants and thrombolytics interfere with ulcerated plaque healing and can worsen disease
- investigations
  - eosinophilia, eosinophiluria, and hypocomplementemia
  - renal biopsy: needle-shaped cholesterol clefts (due to tissue-processing artifacts) with surrounding tissue reaction in small-/medium-sized vessels

- treatment
  - no effective treatment; avoid angiographic and surgical procedures in patients with diffuse atherosclerosis, medical therapy for concomitant cardiovascular disease
- prognosis: poor overall, at least one third will develop ESRD

3. THROMBOTIC MICROANGIOPATHY

- see Hematology, H23
- etiologies include the spectrum of TTP-HUS, DIC, severe preeclampsia, drug-induced, complement mediated, metabolism-mediated, and coagulation-mediated
- the enzyme ADAMTS13 is reduced in TTP, and ADAMTS13 autoantibodies are useful for diagnosing TTP
- events leading to HUS often begin with the ingestion of Shiga toxin-producing E. coli
- renal involvement more common in HUS than TTP
- renal involvement characterized by fibrin thrombi in glomerular capillary loops ± arterioles
- treatment
  - depends on cause
  - supportive therapy
  - TTP-HUS: plasma exchange, corticosteroids
  - eculizumab (monoclonal antibody against complement C5) for Complement mediated HUS (previously known as atypical HUS)
- avoid platelet transfusions and ASA

4. CALCINEURIN INHIBITOR NEPHROPATHY

- secondary to the use of cyclosporine and tacrolimus
- causes both acute reversible and chronic, largely irreversible nephrotoxicity
- major cause of kidney failure in other solid organ transplants (e.g. heart)
- acute: due to afferent and efferent arteriolar vasoconstriction leading to decreased GFR (tubular vacuolization)
  - prerenal azotemia
  - treatment: calcium channel blockers or prostaglandin analogs, reduce dose of cyclosporine or switch to another immunosuppressive drug
- chronic: result of obliterative arteriolopathy causing interstitial nephritis and CKD (striped fibrosis), less frequent now due to lower doses of calcineurin inhibitors

Reduced Exposure to Calcineurin Inhibitors in Renal Transplantation (ELITE-Symphony Trial)
NEJM 2007;257:2562-2575
Study: Multicentre, RCT with 12 mo follow-up.
Patients: 1645 patients scheduled to receive a single organ kidney transplant.
Intervention: Mycophenolate mofetil, corticosteroids, and either: 1) standard dose cyclosporine; 2) low dose cyclosporine with daclizumab induction; 3) low dose tacrolimus with daclizumab induction; 4) low dose sirolimus with daclizumab induction.
Primary Outcome: Estimated Cockcroft-Gault GFR 12 mo after transplantation.
Results: The tacrolimus arm showed significantly higher eGFR at 12 mo compared to all other arms (65.4 mL/min vs. 57.1, 59.4, 56.7 for arms 1, 2, 4 respectively, P≤0.001). The tacrolimus arm also showed decreased rates of acute rejection at 6 mo and 12 mo vs. all arms (P<0.001), improved allograft survival against standard dose cyclosporine and sirolimus, and decreased treatment failure against all other arms. There was no difference in overall patient survival between groups. Sirolimus had the highest incidence of lymphoceles, delayed wound healing, and serious adverse events; tacrolimus had significantly higher rates of new-onset DM; and cyclosporine regimes had the lowest incidence of diarrhea but highest opportunistic infection rates.
Conclusion: Immunosuppression regiments using low dose tacrolimus and daclizumab induction decrease nephrotoxicity while maintaining therapeutic immunosuppression in renal transplant patients.

Analgesic Nephropathies

1. Vasomotor AKI

- clinically: develop prerenal azotemia days after NSAID initiations
- normally prostaglandins vasodilate afferent renal arteriole to maintain blood flow
- NSAIDs act by inhibiting cyclooxygenase activity, thereby preventing prostaglandin synthesis and causing renal ischemia
- more common in elderly, underlying renal disease, hypovolemia (diuretics, CHF, cirrhosis, nephrotic syndrome)
- treatment: discontinue NSAID, dialysis rarely needed

2. Acute Interstitial Nephritis

- caused by fenoprofen (60%), ibuprofen, naproxen
- may be associated with minimal change glomerulopathy and nephrotic range proteinuria
- resolves eventually with discontinuation of NSAID, may require interval dialysis
- short-term high dose steroids (1 mg/kg/d of prednisone) may hasten recovery

3. Chronic Interstitial Nephritis

- due to excessive consumption of antipyretics (phenacetin or acetaminophen) in combination with NSAIDs
- seen in patients who also have emotional stress, psychiatric symptoms, and GI disturbance
- papillary necrosis occurs
  - gross hematuria, flank pain, declining renal function
  - calyceal filling defect seen with IVP – "ring sign"
- increased risk of transitional cell carcinoma of renal pelvis
- good prognosis if discontinue analgesics

4. Acute Tubular Necrosis

- can be caused by acetaminophen
  - incidence of renal dysfunction is related to the severity of acetaminophen ingestion
- vascular endothelial damage can also occur
- both direct toxicity and ischemia contribute to the tubular damage
- renal function spontaneously returns to baseline within 1-4 wk
- dialysis may be required during the acute episode of ingestion

5. Other Effects of NSAIDs
- sodium retention (2° to reduced GFR)
- hyperkalemia, HTN (2° to hyporeninemic hypoaldosteronism)
- excess water retention (2° to loss of antagonistic effect of prostaglandins on ADH)

Systemic Disease with Renal Manifestation

Diabetes

- diabetic nephropathy is a slow, progressive increase in albuminuria, followed by a decrease in eGFR <60 later in disease course
- key risk factors include:
  - long duration of diabetes
  - non-optimal glycemic control, blood pressure, and plasma lipid control
  - obesity
  - cigarette smoking
- most common cause of end-stage renal failure in North America
- 50% of patients with diabetes will develop nephropathy
- greater burden in Indigenous communities
  - in Indigenous youth diagnosed with diabetes before age 20, risk of developing ESRD was 2.59 times higher than non-Indigenous people with diabetes
  - 55.1% of Indigenous individuals diagnosed with diabetes had chronic kidney disease
- at diagnosis up to 30% of patients with type 2 DM have albuminuria (75% A2 albuminuria, 25% overt nephropathy)
- A2 albuminuria (30 -300 mg/d) is a risk factor for progression to overt nephropathy and cardiovascular disease
- once A3 albuminuria (>300 mg/d) is established, renal function declines, 50% of patients reach ESRD within 7-10 yr
- associated with HTN and diabetic retinopathy (especially type 1 DM) and/or neuropathy (especially type 2 DM)
- indication of possible non-diabetic cause of renal disease in patients with DM
  - rising Cr with little/no proteinuria
  - lack of retinopathy or neuropathy (microvascular complications)
  - persistent hematuria (microscopic or macroscopic)
  - signs or symptoms of other systemic disease
  - time course of kidney disease progression disproportionate with length of diabetes; i.e. renal disease in a patient with short duration of DM; rapidly rising Cr.
  - family history of non-diabetic renal disease (e.g. PKD, Alport's)

DM is one of the causes of ESRD that does not result in small kidneys at presentation of ESRD; the others are amyloidosis, HIV nephropathy, PKD, and multiple myeloma

Abnormal Urine ACR Values from 2018 Diabetes Canada CPG
≥2.0 mg/mmol in males and females

ACEI can cause hyperkalemia; therefore, be sure to watch serum K^+, especially if patient has DM and renal insufficiency

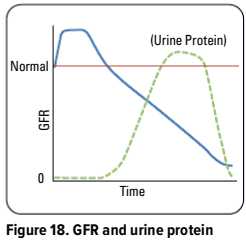

Figure 18. GFR and urine protein over time in DM

DIABETIC RENAL COMPLICATIONS

1. Progressive Glomerulosclerosis
- classic diabetic glomerular lesion: Kimmelstiel-Wilson nodular glomerulosclerosis (15-20%)
- more common lesion is diffuse glomerulosclerosis with a uniform increase in mesangial matrix

Table 14. Stages of Diabetic Progressive Glomerulosclerosis

	Stage 1	Stage 2	Stage 3	Stage 4
Clinical	↑GFR (120-150%) – compensatory hyperfiltration	Detectable A2 albuminuria (30-300 mg/24 h)	A3 albuminuria (>300 mg/24 h)	
		ACR 2.0-20 mg/mmol (18-180 mg/d)	ACR >20 mg/mmol, (>180 mg/d)	↓ GFR
			Proteinuria (positive urine dipstick)	
			Normal GFR	
Pathological	± slightly ↑ mesangial matrix		↑↑↑ mesangial matrix	Sclerosed glomeruli
				<20% glomerular filtration surface area present

Protein Restriction for Diabetic Renal Disease
Cochrane DB Syst Rev 2007;4:CD002181
Purpose: To review the effects of dietary protein restriction on the progression of diabetic nephropathy.
Study Selection: RCTs and before and after studies of the effects of restricted protein diet on renal function in subjects with DM. 12 studies were reviewed.
Results: The risk of ESRD or death was lower in patients on low-protein diet. In patients with type 1 DM no effect on GFR was noted in the low-protein diet group.

See Landmark Nephrology Trials table for more information on ONTARGET, which details the efficacy of ACEI/ARB combination therapy on renal outcomes in patients with atherosclerotic vascular disease or T2DM. ± slightly ↑ mesangial matrix

2. Accelerated Atherosclerosis
- common
- leads to decreased GFR
- may increase angiotensin II production resulting in increased BP
- increased risk of ATN secondary to contrast media

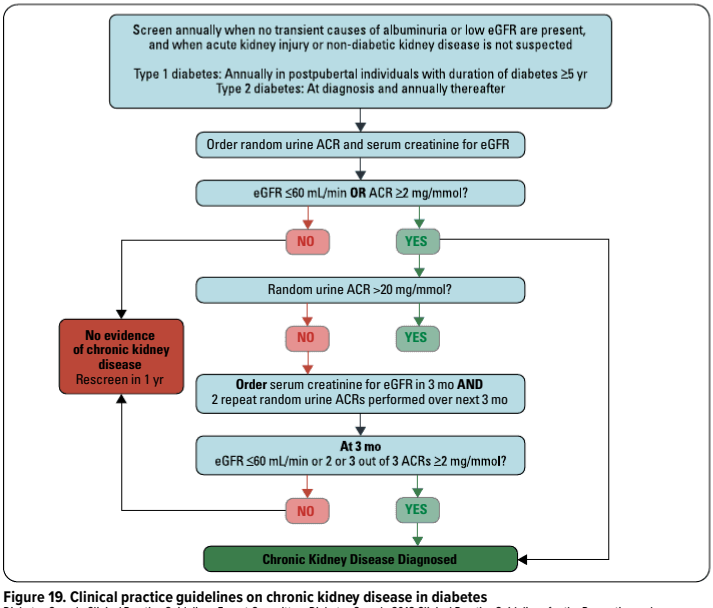
See Landmark Nephrology Trials table for more information on CREDENCE which details the efficacy of canagliflozin (SGLT2 inhibitor) on renal outcomes in patients with T2DM an diabetic nephropathy

3. Autonomic Neuropathy
- causes atonic bladder, which leads to functional obstruction and urinary retention
- residual urine promotes infection
- obstructive nephropathy

4. Papillary Necrosis
- type 1 DM susceptible to ischemic necrosis of medullary papillae
- sloughed papillae may obstruct ureter
- can present as renal colic or with obstructive features ± hydronephrosis

Priorities in the Management of Patients with DM
1. vascular protection for all patients with DM
   - ACEI, antiplatelet therapy (as indicated)
   - BP control, glycemic control, lifestyle modification, lipid control
   - SGLT2 inhibition (i.e. canagliflozin, dapagliflozin, and empagliflozin) provides renoprotection independent of glycemic effects
   - mineralocorticoid receptor antagonists (i.e. finerenone) provide renoprotection of top of RAAS blockade
2. optimization of BP in patients who are hypertensive
   - treat according to HTN guidelines (current target <130/80)
3. renal protection for DM patients with nephropathy (even in absence of HTN)
   - 1st line: ACEI or ARB
   - 2nd line agents:dihydropyridine calcium channel blockers
   - combination of ACEI and ARB not recommended
4. smoking cessation

- check serum Cr and K^+levels within 1 wk of initiating ACEI or ARB and at time of acute illness
- serum Cr can safely be allowed to rise up to 30% with initiation of ACEI or ARB, usually stabilizes after 2-4 wk, monitor for significant worsening of renal function or hyperkalemia
- if >30% rise in serum Cr or hyperkalemia, discontinue medication and consider 2nd line agent
- consider holding ACEI, ARB, and/or diuretic with acute illness and in women before pregnancy
- consider referral to nephrologist if ACR >60 mg/mmol, eGFR <30 mL/min, progressive loss of kidney function, inability to achieve BP targets, or inability to stay on ACEI or ARB



Screen annually when no transient causes of albuminuria or low eGFR are present, and when acute kidney injury or non-diabetic kidney disease is not suspected
Type 1 diabetes: Annually in postpubertal individuals with duration of diabetes ≥5 yr
Type 2 diabetes: At diagnosis and annually thereafter
Order random urine ACR and serum creatinine for eGFR
eGFR ≤60 mL/min OR ACR ≥2 mg/mmol?
NO
YES
Random urine ACR >20 mg/mmol?
NO
YES
No evidence of chronic kidney disease
Rescreen in 1 yr
Order serum creatinine for eGFR in 3 mo AND
2 repeat random urine ACRs performed over next 3 mo
At 3 mo
eGFR ≤60 mL/min or 2 or 3 out of 3 ACRs ≥2 mg/mmol?
NO
YES
Chronic Kidney Disease Diagnosed

Figure 19. Clinical practice guidelines on chronic kidney disease in diabetes
Diabetes Canada Clinical Practice Guidelines Expert Committee. Diabetes Canada 2018 Clinical Practice Guidelines for the Prevention and Management of Diabetes in Canada. Can J Diabetes 2018;42(Suppl 1):S1-S325

Scleroderma

- see Rheumatology, RH14
- 50% of patients with scleroderma have renal involvement (mild proteinuria, high Cr, HTN)
- renal involvement usually occurs early in the course of illness
- histology: media thickened, "onion skin" hypertrophy of small renal arteries, fibrinoid necrosis of afferent arterioles and glomeruli, TMA
- 10-15% of scleroderma patients have a "scleroderma renal crisis" (occurs in first few years of disease, associated with prednisone dose ≥15mg / d and cyclosporine use): malignant HTN, ARF, microangiopathy, volume overload, visual changes, HTN encephalopathy
- treatment: BP control with ACEI slows progression of renal disease

Multiple Myeloma

- see Hematology, H51
- malignant proliferation of plasma cells in the bone marrow with the production of monoclonal immunoglobulins
- patients may present with severe bone disease and renal failure
- light chains are filtered at the glomerulus and appear as Bence-Jones proteins in the urine (monoclonal light chains)
- kidney damage can occur by several mechanisms
  - hypercalcemia
  - light chain cast nephropathy or "myeloma kidney"
  - hyperuricemia
  - infection
  - primary (AL) amyloidosis and secondary (AA) amyloidosis: predominantly manifesting as proteinuria with or without nephrotic syndrome
  - monoclonal Ig deposition disease
  - diffuse tubular obstruction
- light chain cast nephropathy
  - large tubular casts in urine sediment (light chains + Tamm-Horsfall protein)
  - proteinuria and renal insufficiency can progress rapidly to kidney failure
- monoclonal immunoglobulin deposition disease
  - deposits of monoclonal Ig in kidney, liver, heart, and other organs
  - mostly light chains (85-90%)
  - causes nodular glomerulosclerosis (similar to diabetic nephropathy) or MPGN
- fibrillary/ immunotactoid Glomerulonephritis
- cryoglobulinemia (Type I) (see *NP27*)
- lab features: increased BUN, increased Cr, urine protein immunoelectrophoresis positive for Bence-Jones protein (not detected on urine dipstick)
- poor candidates for kidney transplantation

Malignancy

- cancer can have many different renal manifestations
- kidney transplantation cannot be performed if there is a malignancy. Nephrology considerations for malignant presentations include:
  - solid tumours: mild proteinuria or membranous GN
  - lymphoma: minimal change GN (Hodgkin's) or membranous GN (non-Hodgkin's)
  - renal cell carcinoma
  - tumour lysis syndrome: hyperuricemia, diffuse tubular obstruction, hyperkalemia, hyperphosphatemia, hypocalcemia, hyperuricemia, elevated LDH, and lactic acidosis
  - chemotherapy (especially cisplatin): ATN or chronic TIN
  - pelvic tumours/metastases: postrenal failure secondary to obstruction
  - primary (AL) amyloidosis and secondary (AA) amyloidosis: predominantly manifesting as proteinuria with or without nephrotic syndrome
  - radiotherapy (radiation nephritis)

Chronic Kidney Disease

Definition

- progressive abnormalities of kidney function for ≥3 mo, with either
  - GFR <60 mL/min/1.73 m ^{2}; or
  - markers of kidney damage, including:
    - hematuria, proteinuria, or anatomic abnormalities

Clinical Features

- many patients are asymptomatic till alte stages of disease
- cardiovascular: HTN, CHF (volume overload, HTN, and anemia), pericarditis (uremia)
- GI: N/V, anorexia, dysgeusia (GI symptoms typically only manifest in CKD G5)

2016 CCS Guidelines for the Management of Dyslipidemia for the Prevention of CVD in the Adult – Chronic Kidney Disease
Can J Cardiology 2016;32:1263-82
Recommendations:
Adults ≥50 yr with CKD (GFR <60 mL/min/1.73 m²) should receive treatment with a statin or a statin/ezetimibe combination.
Initiation of lipid-lowering therapy is not recommended for adults with dialysis-dependent CKD however, if already receiving it at the time of dialysis initiation, it should be continued.
Statin therapy should be used in adults with kidney transplantation.

Incidence of Etiologies of CKD	
DM	42.9%
HTN	26.4%
Glomerulonephritis	9.9%
Other/Unknown	7.7%
Interstitial nephritis/ Pyelonephritis	4.0%
Cystic/Hereditary/Congenital	3.1%
Secondary GN/Vasculitis	2.4%

- neurologic: lethargy, confusion, neuropathy, seizures, asterixis, hyperreflexia, restless leg syndrome, encephalopathy (uremia)
- hematologic: normocytic normochromic anemia (reduced EPO), bleeding due to platelet dysfunction (uremia)
- endocrine/metabolic: Ca^{2+}, PO_4^{3-} disturbances, hyperphosphatemia, hypocalcaemia, secondary hyperparathyroidism, reduced renal production of 1,25-dihydroxy vitamin D, osteopenia/osteoporosis
- sexual/reproductive: hypothalamic pituitary disturbances, infertility
- pruritus: multifactorial etiology

Table 15. Stages of CKD (KDIGO, 2013)

			Persistent Albuminuria Categories		
		GFR (mL/min/1.73 m²)	A1 <30 mg/g <3 mg/mmol	A2 30-300 mg/g 3-30 mg/mmol	A3 >300 mg/g >30 mg/mmol
GFR Categories (mL/min/1.73 m²)	G1	≥90	1 if CKD	1	2
	G2	60-89	1 if CKD	1	2
	G3a	45-59	1	2	3
	G3b	30-44	2	3	3
	G4	15-29	3	3	4+
	G5	<15 (kidney failure)	4+	4+	4+

The numbers in the boxes are a reflection of the risk of progression and are a guide to the frequency of monitoring/year
"D" is added to G5 for patients requiring dialysis
Classification is based on cause, GFR, and amount of albuminuria
Rate of progression and risk of complications are determined by the cause of CKD

Management of Complications of CKD

Management of Chronic Kidney Disease

- diet
  - preventing HTN and volume overload
  - low-protein diet with adequate caloric intake in order to limit endogenous protein catabolism. Not recommended in children as protein is needed for growth. Literature is conflicted regarding use of protein restriction in certain other populations
  - Na +restriction (<2 g/d) if HTN, CHF, or oliguria are present
  - K +restriction (40-60 mmol/d), phosphate (1 g/d) for hyperkalemia and hyperphosphatemia respectively," magnesium (avoid antacids; preventing uremia and potentially delaying decline in GFR) intake
- medical
  - adjust dosages of renally excreted medications
  - HTN: target BP now as per the most recent CSN guideline: systolic <120
  - ACEI/ARB (target SBP 120 mmHg) in patients without kidney transplant; CCB/ARB (target BP 130/80 mmHg) in patients receiving kidney transplant
  - dyslipidemia: statins (target LDL <2 mmol/L)
  - calcium and phosphate disorders
    - consider vitamin D and calcitriol (1,25-dihydroxy-vitamin D) for secondary hyperparathyroidism
    - calcium carbonate as a phosphate binder for hyperphosphatemia
    - sevelamer or lanthanum salts as a phosphate binder if both hypercalcemic and hyperphosphatemic
    - parathyroidectomy or cinacalcet for tertiary hyperparathyroidism (sensitizes parathyroid to Ca^{2+}, decreasing PTH)
  - metabolic acidosis: sodium bicarbonate
  - anemia: IV vs PO iron if TSAT ≤ 20% or ferritin ≤ 200 and an increase in Hb/decrease in ESA is desired; avoid IV in active systemic infections. Erythropoietin-Stimulant Agent (ESA) initiation if Hb <100, with target 95-110. Epoetin-alfa, or darbepoetin are erythropoesis stimulating agents. Contraindications: active malignancy, history of stroke, history of malignancy
  - platelet dysfunction: DDAVP if patient has clinical bleeding or invasive procedures
  - dialysis (see Indications for Dialysis in *Chronic Kidney Disease, NP41*)
  - renal transplantation for end stage kidney disease

Prevention of Progression

- as above
- control of HTN, DM (HbA1c <7%), cardiovascular risk factors (e.g. smoking cessation, physical activity, weight loss)
- avoid nephrotoxins such as NSAIDs, COX2 inhibitors, IV contrast in patients with eGFR <60 mL/min/1.73 m²
- address reversible causes of AKI

Management of Complications of CKD

NEPHRON
Nephrotoxins: avoid nephrotoxic drugs (ASA, gentamicin) and adjust doses of renally excreted medications
HTN
RBCs: manage anemia with erythropoietin
Osteodystrophy: give calcium between meals (to increase Ca^{2+}) and calcium with meals (to bind and decrease PO_4^{3-})
Nitrogen diet
Electrolytes: monitor K+
pH: metabolic acidosis

Effects of Lowering LDL Cholesterol with Simvastatin and Ezetimibe in Patients with Chronic Kidney Disease
Lancet 2011;377:2181-2192
Purpose: To assess the efficacy and safety of the combination of simvastatin and ezetimibe in patients with moderate to severe CKD.
Study: Randomized, double-blind trial with 9270 patients with CKD with no known history of myocardial infarction or coronary vascularization. Patients were randomized to simvastatin 20 mg plus ezetimibe 10 mg daily vs. matching placebo.
Primary Outcome: First major atherosclerotic event (non-fatal myocardial infarction or coronary death, non-hemorrhagic stroke, or any arterial revascularization procedure).
Results: The simvastatin plus ezetimibe group was associated with an average LDL cholesterol difference of 0.85 mmol/L during a median follow-up of 4.9 yr. There was a 17% proportional reduction in major atherosclerotic events in the simvastatin plus ezetimibe group compared to placebo.
Conclusions: Reducing LDL cholesterol with a treatment regimen of simvastatin plus ezetimibe safely reduced the incidence of major atherosclerotic events in patients with moderate to severe CKD.

Renin Angiotensin System Blockade and Cardiovascular Outcomes in Patients with Chronic Kidney Disease and Proteinuria: A Meta-Analysis
Am Heart J 2008;155:791-805
Purpose: To evaluate the role of RAS blockade in improving cardiovascular CV outcomes in patients with CKD.
Study Selection: RCT that analyzed CV outcomes in patients with CKD/proteinuria treated with RAS blockade (ACEI/ARB). RAS blockade-based therapy was compared with placebo and control therapy (β-blocker, calcium-channel blockers, and other antihypertensive-based therapy) in the study.
Results: Twenty-five trials (n=45758) were included. Compared to placebo, RAS blockade reduced the risk of heart failure in patients with diabetic nephropathy. In patients with non-diabetic CKD, RAS blockade decreased CV outcome compared to control therapy.
Conclusions: RAS blockade reduced CV outcomes in diabetic nephropathy as well as non-diabetic CKD.

Hypertension

- see Family Medicine, FM37
- HTN occurs in about 20% of population
- etiology classified as primary ("essential;" makes up 90% of cases) or secondary
- primary HTN can cause kidney disease (hypertensive ischemic nephropathy), which may in turn exacerbate the HTN
- secondary HTN can be caused by renal parenchymal or renal vascular disease

Hypertensive Nephrosclerosis

Table 16. Chronic vs. Malignant Hypertension

	Chronic Nephrosclerosis	Malignant Nephrosclerosis
Histology	Slow vascular sclerosis with ischemic changes affecting intralobular and afferent arterioles	Fibrinoid necrosis of arterioles, disruption of vascular endothelium
Clinical Picture	Black race (ApoL1 mediated hypertension nephrosclerosis), underlying CKD, chronic hypertensive disease	Acute elevation in BP (dBP >120 mmHg) HTN encephalopathy, acute end organ damage (papilledema, stroke, ACS, AKI)
Urinalysis	Mild to severe proteinuria, normal urine sediment	Proteinuria and hematuria (RBC casts)
Therapy	Blood pressure control, (target <120/80) with frequent follow-up	Lower dBP to 100-110 mmHg within 6-24 h More aggressive treatment can cause ischemic event Identify and treat underlying cause of HTN
Prognosis	Can progress to renal failure if HTN poorly controlled	Lower survival if renal insufficiency develops

Effects of Intensive BP Control in CKD
J Am Soc Nephrol 2017;28(9):2812-2823
Purpose: To evaluate appropriate target for BP in patients with CKD and HTN.
Methods: RCT subgroup analyses of participants in the Systolic Blood Pressure Intervention Trial (SPRINT). Participants were randomly assigned to intensive group (sBP <120 mmHg) or standard group (sBP <140 mmHg).
Results: The intensive group had a lower rate of all-cause death (HR 0.72, 95% CI 0.63-1.05) and major CV events (HR 0.81, 95% CI 0.63-1.05). Decreases in eGFR were comparable between treatment groups (HR 0.90, 95% CI 0.44-1.83). Treatment effects did not differ between participants with and without CKD.
Conclusions: In patients with CKD and HTN without diabetes, target sBP of 120 mmHg vs. 140 mmHg reduced rates of major CV events and all-cause death.

Renovascular Hypertension

- see *Vascular Diseases of the Kidney, NP31*

Renal Parenchymal Hypertension

- HTN secondary to GN, AIN, diabetic nephropathy, or any other chronic renal disease
- mechanism of HTN not fully understood but may include:
  - excess RAAS activation due to inflammation and fibrosis in multiple small intra-renal vessels
  - production of unknown vasopressors, lack of production of unknown vasodilators, or lack of clearance of endogenous vasopressor
  - ineffective sodium excretion with fluid overload

Investigations

- as well as investigations for renovascular HTN, additional tests may include
  - 24 h urinary estimations of CrCl and protein excretion
  - imaging (U/S, CT)
  - serology for collagen-vascular disease
  - renal biopsy (very rarely if at all)

Treatment

- most chronic renal disease is irreversible; however, treatment of HTN can slow the progression of renal insufficiency
- control ECF volume: Na^+-restriction (2 g/d intake), diuretic, dialysis with end-stage disease
- ACEI or ARB may provide added benefit (monitor K^+ and Cr) if there is significant proteinuria (>300 mg/d)

Cystic Diseases of the Kidney

- characterized by epithelium-lined cavities filled with fluid or semisolid debris within the kidneys
- includes: simple cysts (present in 50% of population >50), medullary cystic kidney, medullary sponge kidney, polycystic kidney disease (autosomal dominant and recessive), and acquired cystic kidney disease (in chronic hemodialysis patients)

Adult Polycystic Kidney Disease

- autosomal dominant; at least 2 genes: *PKD1* (chr 16p) and *PKD2* (chr 4q)
- PKD1 (1:400), PKD2 (1:1000) accounts for about 10% of cases of renal failure
- patients generally heterozygous for mutant *PKD* gene but accumulate a series of second 'somatic hits' precipitating the condition
- PKD gene defect leads to abnormal proliferation and apoptosis of tubular epithelial cells leading to cyst growth
- most common extrarenal manifestations: multiple asymptomatic hepatic cysts (33%), mitral valve prolapse (25%), intracranial arterial aneurysm (10%), diverticulosis, hernias (abdominal/inguinal)

Hypercalcemia complicates many cancers and can cause multiple kinds of renal disorders (renal vasoconstriction with reduced GFR, salt-wasting with volume depletion, risk of calcium kidney stones)

- polycystic liver disease rarely causes liver failure, but may form the indication of liver transplant due to space occupying impact which can lead to reduced oral intake and malnutrition
- less common extrarenal manifestations: cysts in pancreas, spleen, thyroid, ovary, seminal vesicles, and aorta

Signs and Symptoms
- often asymptomatic; discovered incidentally on imaging or by screening those with FHx
- acute abdominal flank pain/dull lumbar back pain (source: infection of renal cysts, hemorrhaging into cysts, kidney stones)
- hematuria (frequently initial sign is microscopic hematuria, otherwise gross hematuria)
- nocturia (urinary concentrating defect)
- extrarenal presentation (e.g. ruptured berry aneurysm, diverticulitis, mitral valve prolapse, aortic regurgitation, tricuspid valve prolapse)
- HTN (increased renin due to focal compression of intrarenal arteries by cysts) (60-75%)
- ± palpable kidneys

Common Complications
- urinary tract and cyst infections, HTN, chronic renal failure, nephrolithiasis (5-15%), flank and chronic back pain

Clinical Course
- polycystic changes are always bilateral and can present at any age
- clinical manifestations rare before age 20-25
- kidneys are normal at birth but may enlarge to 10x normal size
- variable progression to renal functional impairment (ESRD in up to 50% by age 60)

Investigations
- U/S is confirmatory (enlarged kidneys, multiple cysts throughout renal parenchyma, increased cortical thickness, splaying of renal calyces)
- CT abdomen with contrast (for equivocal cases, occasionally reveals more cystic involvement)
- MRI for kidney volume measurement
- gene linkage analysis for *PKD1* for asymptomatic carriers
- Cr, BUN, urine R&M (to assess for hematuria)

Treatment
- non-pharmacological:
  - educate patient and family about disease, its manifestations, and inheritance pattern
  - genetic counseling: transmission rate 50% from affected parent
  - avoid contact sports due to greater risk of injury to enlarged kidneys
- pharmacological:
  - monitor blood pressure and treat HTN with ACEI (target ≤ 110/75 mmHg)
  - encourage free water intake >2-3L/d to reduce endogenous ADH levels (ADH promotes cyst growth)
  - tolvaptan (vasopressin receptor (V2R) antagonist) has been used to slow the decline of renal function (18-50 y/o, eGFR >45, TKV >750 mL), however, its use has been limited by side effects
  - TMP/SMX, ciprofloxacin: able to penetrate cyst walls, achieve therapeutic levels
  - dialysis or transplant for ESRD (disease does not recur in transplanted kidney)
  - may require nephrectomy for symptomatic relief of pain or due to recurrent infections
- complication prevention:
  - adequate hydration to prevent stone formation
  - screen for cerebral aneurysms if family history of aneurysmal hemorrhages
  - prevention and early treatment of urinary tract and cyst infections (avoid instrumentation of GU tract)

Extrarenal Manifestations of PKD
Hepatic cysts
Mitral valve prolapse
Cerebral aneurysms
Diverticulosis

Tolvaptan in Later-Stage Autosomal Dominant Polycystic Kidney Disease
NEJM 2017;377:1930-1942
Purpose: To evaluate the efficacy and safety of the vasopressin V2-receptor antagonist tolvaptan in patients with later-stage autosomal dominant polycystic kidney disease.
Methods: Phase III, randomized withdrawal, multicentre, placebo-controlled, double-blind trial.
Results: Change in estimated GFR from baseline was -2.34 ml/min/1.732 in the tolvaptan group (95% CI, -2.81 to -1.87) vs. -3.61 ml/min/1.732 m^2in the placebo group (95% CI, -4.08 to -3.14).
Conclusions: Tolvaptan resulted in a slower decline than placebo in the estimated GFR over a 1 yr period.

Autosomal Recessive Polycystic Kidney Disease
- 1 in 20000 incidence
- prenatal diagnosis by enlarged kidneys (due to cystic dilatation of the collecting ducts); if significant in utero can result in Potter sequence
- perinatal death from respiratory failure
- associated with hepatic fibrosis
- patients who survive perinatal period develop CHF, HTN, CKD, portal hypertension
- treated with dialysis, kidney, and/or liver transplant

Medullary Sponge Kidney
- common, autosomal dominant, usually diagnosed in 4th-5th decades
- multiple cystic dilatations in the collecting ducts of the medulla
- renal stones, hematuria, and recurrent UTIs are common features
- an estimated 10% of patients who present with renal stones have medullary sponge kidney

- nephrocalcinosis on abdominal x-ray in 50% patients, often detect asymptomatic patients incidentally
- diagnosis: contrast filled medullary cysts on IVP leading to characteristic radial pattern ("bouquet of flowers"), "Swiss cheese" appearance on histological cross-section
- treat UTIs and stone formation as indicated
- does not result in renal failure

End Stage Renal Disease

Definition
- ESRD represents an irreversible decline in kidney function requiring renal replacement therapy
- glomerular filtration rate less than 15 mL/min/1.73 m^2 body surface area

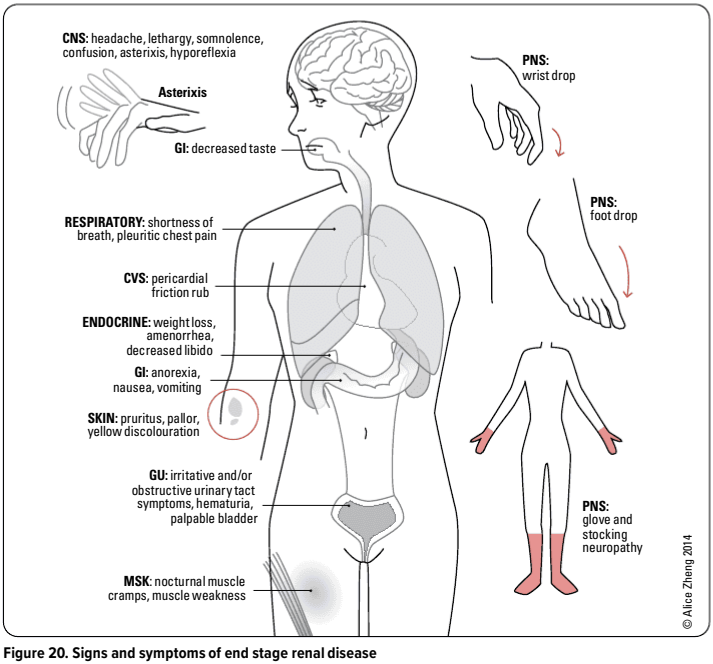
Risk Factors
- amount of daily proteinuria (strongest predictor of progression to ESRD)
- hypertension, age, history of chronic renal insufficiency, DM, tobacco, analgesic use, ethnicity (increased incidence in Black individuals), lower socioeconomic status, obesity, hyperuricemia, and family history of kidney disease

Presentation of End Stage Kidney Disease

1. Volume Overload
- due to increase in total body Na^+ content
- signs: weight gain, HTN, pulmonary, or peripheral edema

2. Electrolyte Abnormalities
- high
  - K^+ (decreased renal excretion, medications including RAAS blockers, diet with high K)
  - PO_4^{3-} (decreased renal excretion)
- low
  - Ca^{2+} (decreased vitamin D activation, hyperphosphatemia, hypoalbuminemia)
  - HCO_3^- (inability of kidney to excrete the acid load and generate bicarb)

3. Uremic Syndrome
- manifestations result from retention of uremic toxins as well as hormone deficiencies



CNS: headache, lethargy, somnolence, confusion, asterixis, hyporeflexia
Asterixis
GI: decreased taste
RESPIRATORY: shortness of breath, pleuritic chest pain
CVS: pericardial friction rub
ENDOCRINE: weight loss, amenorrhea, decreased libido
GI: anorexia, nausea, vomiting
SKIN: pruritus, pallor, yellow discolouration
GU: irritative and/or obstructive urinary tact symptoms, hematuria, palpable bladder
MSK: nocturnal muscle cramps, muscle weakness
PNS: wrist drop
PNS: foot drop
PNS: glove and stocking neuropathy
© Alice Zheng 2014

Figure 20. Signs and symptoms of end stage renal disease

Complications
- CNS: encephalopathy, decreased LOC, stupor, seizure
- cardiovascular system: cardiomyopathy, CHF, arrhythmia, pericarditis, atherosclerosis
- hematologic: anemia, bleeding tendency (platelet dysfunction), infections
- endocrine
  - decreased testosterone, estrogen, progesterone
  - increased FSH, LH
  - insulin resistance, decreased insulin requirements
  - hypertriglyceridemia, accelerated atherogenesis
- metabolic: anion gap and non anion gap metabolic acidosis
- renal osteodystrophy: secondary increased PTH due to decreased Ca^{2+}, high PO_4^{3-}, and low active vitamin D (1,25-OH vitamin D3)
  - osteitis fibrosa cystica
- dermatologic: pruritus, ecchymosis, hematoma, calciphylaxis (vascular Ca^{2+}deposition)

Treatment
- therapies include, dialysis, renal transplant or non-dialytic conservative management
- dialysis is the preferred treatment for ESRD
- initiation of chronic dialysis has major implications on patients and healthcare system

Renal Replacement Therapy

Dialysis

Indications for Dialysis in Chronic Kidney Disease

Table 17. Indications for Dialysis

Absolute Indications	Relative Indications
Volume overload*	Anorexia and dysgeusia
Hyperkalemia*	Decreased cognitive functioning
Severe metabolic acidosis*	Profound fatigue and weakness
Neurologic signs or symptoms of uremia (encephalopathy, neuropathy, seizures)	Severe anemia unresponsive to erythropoietin
Uremic pericarditis	Persistent severe pruritus
Refractory accelerated HTN	Restless leg syndrome
Clinically significant bleeding diathesis	
Persistent severe N/V	

*Unresponsive to medications

- there are 2 types of dialysis:
  - hemodialysis and hemodiafiltraion (both are blood based therapies)
  - peritoneal dialysis
- outpatient dialysis can be done in centre (hospital) or at home (PD and Home hemodialysis).
- decision to start dialysis in ESRD should be symptom driven or when GFR reaches approximately ≤10 mL/min
- hemodialysis:
  - blood is filtered across a semipermeable membrane removing accumulated toxic waste products, solutes, excess fluid (ultrafiltration), and restoring buffering agents to the bloodstream
  - available as intermittent (e.g. 3-6x/wk), which are in-hospital treatments
  - can be delivered at home or in-centre, nocturnal
  - vascular access can be achieved through a central venous catheter, an artificial AV graft, or an AV fistula
- patients with CKD should be referred for vascular access surgery to attempt construction of a primary AV fistula when their eGFR is <20 mL/min, the serum Cr level quoted as >350 µmol/L, or within 1 yr of an anticipated need
- check Kidney Failure Risk Equation, which provides the 2 and 5 year probability of treated kidney failure for a potential patient with CKD stage 3 to 5
- peritoneal dialysis: peritoneum acts as a semipermeable membrane similar to hemodialysis filter
  - advantages: independence, fewer stringent dietary restrictions, better rehabilitation rates
  - available as continuous ambulatory (CAPD; 2-5 exchanges/d) or automated PD (using cycler machine at night)
- refer patients with chronic renal disease to a nephrologist early on to facilitate treatment and plan in advance for renal replacement therapy (RRT)

How to Write Dialysis Orders (MUST BE INDIVIDUALIZED)
- Filter Type (e.g. F80)
- Length (e.g. 4 h 3x/wk or 2 h daily)
- Q Blood Flow (max 500 cc/min)
- Ultrafiltration (e.g. 2 L or to target dry weight)
- Na+ 140 (can be adjusted by starting at 155 and "ramping" down to minimize cramping)
- K + (based on serum K+)

Serum K+	Dialysate
4-6	1.5
3.5-4	2.5
<3.5	3.5

- Ca^{2+} 1.25
- HCO_3^- 40
- Heparin (none, tight [500 U/h] or full [1000 U/h])
- IV fluid to support BP (e.g. NS)

When to Initiate Dialysis
CrCl <20 mL/min
- Educate patient regarding risks and benefits of dialysis; discuss goals of care, especially in frail older patients.
- if patient indicates preference for hemodialysis, make arrangements for AV access (fistula or graft)

CrCl <10 mL/min
- Dialysis should be initiated when patient has uremic symptoms or refractory metabolic/ electrolyte abnormalities

NOTE
A preemptive transplant can be considered if patient has a living don

Commonly Used Immunosuppressive Drugs

Calcineurin inhibitors
- Cyclosporine
- Tacrolimus

Antiproliferative medications
- Mycophenolate mofetil
- Azathioprine

Other agents
- Sirolimus
- Prednisone

Anti-lymphocyte antibodies
- Thymoglobulin
- Basiliximab

Indications for Dialysis (Refractory to Medical Therapy)

AE IOU
Acidosis
Electrolyte imbalance (K+)
Intoxication (AKI)
Overload (fluid)
Uremia (encephalopathy, pericarditis, urea >35-50 mM)

Table 18. Peritoneal Dialysis vs. Hemodialysis

	Peritoneal Dialysis	Hemodialysis
Rate	Slow	Fast
Location	Home	Home or in-centerdialysis unit
Ultrafiltration	Osmotic pressure via dextrose dialysate	Hydrostatic pressure
Solute Removal	Concentration gradient and convection	Concentration gradient and convection
Membrane	Peritoneum	Semi-permeable artificial membrane (e.g Polysulfone)
Method	Indwelling catheter in peritoneal cavity	Blood flowed extracorporeally through dialysis machine
Complications	Infection at catheter site Bacterial Peritonitis Metabolic effects of glucose Encapsulating peritoneal sclerosis (rare)	Central venous stenosis/ thrombosis Bacteremia (catheter related) Bleeding due to heparin Hemodynamic stress of extracorporeal circuit Disequilibrium syndrome (headache, cerebral edema, hypotension, nausea, muscle cramps related to solute/ water flux over short time) - usually during first few dialysis sessions at start of ESKD
Preferred When	Residual renal function Success depends on presence of residual renal function Hemodynamic instability	Intraperitoneal adhesions Home conditions non-conducive

Renal Transplantation

- provides maximum replacement of GFR
- only done for end stage renl disease and not AKI
- best way to reverse uremic signs and symptoms
  - renal transplantation has been shown to have improved long-term patient survival and greater quality of life over dialysis
- native kidneys usually left in situ
- 2 types: deceased donor, living donor (related or unrelated)
- living donor transplants are associated with better short- and long-term outcomes than deceased donor transplants
- kidney transplanted into iliac fossa, transplant renal artery anastomosed to external iliac artery of recipient
- induction immunosuppression with IV thymoglobulin or basiliximab, followed by maintenance oral immunosuppression with an oral immunosuppression cocktail (usually corticosteroids, calcineurin inhibitor, anti-metabolite)
- long-term monitoring of cyclosporine and tacrolimus levels are required
- 1 yr renal allograft survival rates ≥90%

Intravenous Iron in Patients Undergoing Maintenance Hemodialysis
NEJM 2019;380:447-458
Purpose: To assess the use of high doses of iron in patients undergoing hemodialysis.
Study: Multi-centre, open-label trial with blinded endpoint evaluation.
Population: 2141 adults with ESRD in whom maintenance hemodialysis was initiated no more than 12 mo prior were randomized to high-dose IV iron (median 264 mg monthly) administered proactively (1,093) or low-dose IV iron (median 145 mg monthly) administered reactively (1,048).
Outcome: Primary endpoint was nonfatal myocardial infarction, nonfatal stroke, hospitalization for heart failure, or death.
Results: 29.3% of patients in the high-dose group had a primary endpoint event, compared to 32.3% in the low-dose group. Patients in the high-dose group had a lower median monthly dose of an erythropoiesis-stimulating agent compared to the low-dose group (29,757 IU vs. 38,805 IU).
Conclusions: A high-dose IV iron regimen administered proactively in patients undergoing hemodialysis is superior to a low-dose regimen administered reactively.

Complications

- #1 cause of mortality in transplanted patients is cardiovascular disease
- increased risk of infections (bacterial, viral, fungal, opportunistic)
- new-onset DM (often due to prednisone and calcineurin inhibitors, especially tacrolimus)
- graft rejection (cellular or humoral)
- acute rejection: rise in Cr, fever, hematuria, graft site tenderness, oliguria, although symptoms are very uncommon
- early allograft damage caused by episodes of acute rejection and acute peritransplant injuries
- transplant glomerulopathy from antibody injury
- cyclosporine or tacrolimus nephropathy (see *Small Vessel Disease, NP32*)
- *de novo* GN (membranous, IgA, MPGN)
- BK virus (polyoma virus) nephropathy can result from over-immunosuppression and lead to graft loss
- leading causes of late allograft loss: interstitial fibrosis/tubular atrophy and death with functioning graft
- depends on immunologic and nonimmunologic factors (HTN, hyperlipidemia, age of donor, quality of graft, new onset DM)
- infections (CMV, PJP, and other opportunistic infections usually occur between 1 and 6 mo post-transplant)
- malignancy (skin cancer, Kaposi's sarcoma, non-Hodgkin's lymphoma)

Common Medications

Table 19. Common Medications in Nephrology

Classification	Examples	Site of Action	Mechanism of Action (Secondary Effect)	Indication	Dosing	Adverse Effects
Loop Diuretics	furosemide (Lasix®) bumetanide (Bumex®/ Burinex®) ethacrynate (Edecrin®) torsemide (Demadex®)	Thick ascending limb of Loop of Henle	↓ Na^+/K^+ /2Cl-transport ± renal and peripheral vasodilatory effects (K^+loss; ↑ H^+secretion; ↑ Ca^{2+}excretion)	Management of edema secondary to CHF, nephrotic syndrome, cirrhotic ascites; ↑ free water clearance (e.g. in SIADH-induced hyponatremia), ↓ BP (less effective due to short action)	furosemide: edema: 20-80 mg IV/IM/PO q6-8h (max 600 mg/d) until desired response HTN: 20-80 mg/d PO once daily/ BID dosing IV furosemide is equivalent to 2 x po dose	Allergy in sulfa-sensitive individuals Electrolyte abnormalities; hypokalemia, hyponatremia, hypocalcemia, hypercalciuria (with stone formation) Volume depletion with metabolic alkalosis Precipitates gout attacks
Thiazide Diuretics	hydrochlorothiazide (HCTZ) chlorothiazide (Diuril®) indapamide (Lozol®, Lozide®) metolazone (Zaroxolyn®) chlorthalidone (Hygroton®)	Distal convoluted tubule	Inhibit Na^+/Cl-transporter (K^+ loss; ↑ H^+ secretion; ↓ Ca^{2+} excretion)	1st line for essential HTN Treatment of edema Idiopathic hypercalciuria and stones Diabetes insipidus (nephrogenic)	HCTZ: edema: 25-100 mg PO once daily HTN: 12.5-25 mg PO once daily (max 50 mg/d) nephrolithiasis/hypercalciuria: 25-100 mg once daily	Hypokalemia Increased serum urate levels Precipitates gout attacks, hypercalcemia Elevated lipids Glucose intolerance
Potassium-Sparing Diuretics	spironolactone (Aldactone®) triamterene (Dyrenium®) amiloride (Midamor®)	Cortical collecting duct (↓ Na^+ reabsorption)	Aldosterone antagonist (spironolactone) Block Na^+ channels (triamterene and amiloride)	Reduces K^+ loss caused by other diuretics Edema/hypervolemia Severe CHF, ascites (spironolactone), cystic fibrosis (amiloride ↓ viscosity of secretions)	spironolactone: 25-200 mg/d once daily/BID dosing HTN: 50-200 mg/d once daily/BID dosing Hyperaldosteronism: 100-400 mg/d once daily/BID dosing amiloride: edema/HTN: 5-10 mg PO once daily	Hyperkalemia (caution with ACEI) Triamterene can be nephrotoxic (rare) Nephrolithiasis Gynecomastia (estrogenic effect of spironolactone)
Osmotic Diuretics	mannitol (Osmitrol®) glycerol urea	Renal tubules (proximal and collecting duct)	Non-reabsorbable solutes increase osmotic pressure of glomerular filtrate – inhibits reabsorption of water and ↑ urinary excretion of toxic material	To ↓ intracranial or intraocular pressure Mobilization of excess fluid in renal failure or edematous states	mannitol: ↓ ICP: 0.25-2 g/kg IV over 30-60 min	Transient volume expansion Electrolyte abnormalities (↓/↑ Na^+, ↓/↑ K^+)
ACEI	ramipril (Altace®) enalapril (Vasotec®) lisinopril (Prinivil®) trandolapril (Mavik®) captopril (Capoten®)	Lungs Tissues diffusely	Inhibits angiotensin converting enzyme, preventing formation of angiotensin II Prevents angiotensin II vasoconstricting vascular smooth muscle ➔ net vasodilation ➔ ↓ BP Prevents angiotensin II mediated aldosterone release from adrenal cortex and action on proximal renal tubules ➔ ↑ Na^+ and H_2O excretion ➔ ↓ BP Reduces fibrosis and atherogenesis	HTN Cardioprotective effects Renoprotective effects	ramipril: HTN: 2.5-10 mg PO once daily/BID dosing renoprotective use; 10 mg PO once daily trandolapril: HTN; 1-4 mg PO once daily	Cough Asthma Hyperkalemia Angioedema Agranulocytosis (captopril) AKI Teratogenic
ARB	losartan (Cozaar®) candesartan (Atacand®) irbesartan (Avapro®) valsartan (Diovan®) telmisartan (Micardis®) eprosartan (Teveten®) olmesartan (Olmetec®)	Vascular smooth muscle, adrenal cortex, proximal tubules	Competitive inhibitor at the angiotensin II receptor: prevents angiotensin II vasoconstricting action on vascular smooth muscle ➔ ↓ BP Prevents angiotensin II mediated aldosterone release from adrenal cortex and action on proximal renal tubules ➔ ↑ Na^+ and H_2O excretion	HTN Cardioprotective effects Renoprotective effects	HTN: losartan 25-100 mg PO once daily candesartan 8-32 mg PO once daily irbesartan 150-300 mg PO once daily valsartan 80-320 mg PO once daily telmisartan 20-80 mg PO once daily eprosartan 400-800 mg PO once daily olmesartan 20-40 mg PO once daily	Hyperkalemia Caution – reduce dose in hepatic impairment AKI Teratogenic

Landmark Nephrology Trials

Trial Name	Reference	Clinical Trial Details
ELECTROLYTE DISTURBANCES		
BICAR ICU	Lancet 2018; 392:31-40	**Title**: Sodium bicarbonate therapy for patients with severe metabolic acidaemia in the intensive care unit (BICAR-ICU): a multicentre, open-label, randomized controlled, phase 3 trial **Purpose**: To assess the potential benefits of sodium bicarbonate infusion on outcomes in critically ill patients. **Methods**: A multicenter, open-label, randomized controlled phase 3 trial was conducted in 26 ICUs in France. Critically ill adult patients with severe acidaemia were randomly assigned to receive sodium bicarbonate infusion or no treatment. The primary outcome measured death and organ failure. **Results**: 389 patients were enrolled in the study. The primary outcome occurred in 71% of the control group and 66% of the bicarbonate group. The probability of survival at day 28 was not significantly different between the groups, except for patients in the Acute Kidney Injury Network stratum. Adverse events were more common in the bicarbonate group, but no life-threatening complications were reported. **Conclusions**: Sodium bicarbonate had no effect on the primary outcome in patients with severe metabolic acidaemia, but benefited those with acute kidney injury.
SALT-1	NEJM 2006;16:2099-112	**Title**: Tolvaptan, a Selective Oral Vasopressin V2-Receptor Antagonist, for Hyponatremia **Purpose**: Investigate whether tolvaptan might be of benefit in hyponatremia. **Methods**: Patients with euvolemic or hypervolemic hyponatremia were randomized to oral tolvaptan 15 mg daily or oral matched placebo. The primary endpoints were changes in daily area-under-the-curve for serum Na^+ concentrations. **Results**: Serum Na^+ concentrations increased more in the tolvaptan group than placebo during the first 4 d ($P<0.001$) and after 30 d ($P<0.001$). Side effects included dry mouth, thirst, and increased urination. **Conclusions**: In patients with euvolemic or hypervolemic hyponatremia, tolvaptan, an oral vasopressin V2-receptor antagonist, was effective in increasing serum Na^+ concentrations.
SMART	NEJM 2018; 378:829-39	**Title**: Balanced Crystalloids versus Saline in Noncritically Ill Adults **Purpose**: To examine the clinical impact of using balanced crystalloids compared to saline for routine intravenous fluid therapy in noncritically ill adults in the emergency department. **Methods**: In a single-center trial, noncritically ill adults in the emergency department received either balanced crystalloids or saline for intravenous fluid therapy. The study assessed hospital-free days and major adverse kidney events as outcomes. **Results: 13,347 patients were enrolled, receiving either balanced crystalloids or saline in the emergency department. Hospital-free days were similar between the groups. However, the incidence of major adverse kidney events within 30 d was lower in the balanced crystalloids group compared to saline.** **Conclusions**: No disparity in hospital-free days was observed between balanced crystalloids and saline treatments in noncritically ill adults receiving intravenous fluids.
OPAL-HK	NEJM 2015;372:211-21	**Title**: Patiromer in Patients with Kidney Disease and Hyperkalemia Receiving RAAS Inhibitors **Purpose**: Assess the safety and efficacy of patiromer, a K^+ binder, in treating hyperkalemia. **Methods**: Patients with CKD receiving RAAS inhibitors with serum K^+ levels of 5.1 to 6.5 mmol/L received patiromer for 4 wk. The primary efficacy endpoint was the mean change in serum K^+ levels from baseline to week 4. Subsequently, 107 patients were randomly assigned to patiromer or placebo for the randomized withdrawal phase. **Results**: The median increase in K^+ levels from baseline was greater with placebo than with patiromer ($P<0.001$). A recurrence of hyperkalemia occurred in 60% of placebo patients compared with 15% in the patiromer group, **Conclusions**: In CKD patients receiving RAAS inhibitors and who had hyperkalemia, patiromer treatment was associated with a decrease in serum K^+ levels and a reduction in hyperkalemia recurrence.
DIABETIC NEPHROPATHY		
ACEI and Diabetic	NEJM 1993;329:1456-62	**Title**: The Effect of Angiotensin-Converting-Enzyme Inhibition on Diabetic Nephropathy **Purpose**: Determine whether captopril has kidney-protecting properties independent of BP control in patients with diabetic nephropathy. **Methods**: Patients with insulin-dependent DM were randomized to captopril or placebo. The primary endpoint was a doubling of the baseline serum Cr. **Results**: The associated risk reductions of the primary endpoint was 48% in the captopril group. Serum Cr concentrations doubled in 25 patients in the captopril group compared to 43 patients in the placebo group. The mean rate of decline in Cr clearance was 11% per yr in the captopril group and 17% in the placebo group. **Conclusions**: Captopril protects against deterioration in renal function in insulin-dependent diabetic nephropathy and is significantly more effective than BP control alone.
BENEDICT	NEJM 2004;351:1941-51	**Title**: Preventing Microalbuminuria in Type 2 Diabetes **Purpose**: Assess whether ACEI and non-dihydropyridine calcium channel blockers (CCBs), alone or in combination, prevent microalbuminuria in patients with HTN and T2DM. **Methods**: 1204 patients were randomized to 3 yr of treatment with trandolapril 2 mg daily plus verapamil SR 180 mg daily, trandolapril alone, verapamil alone, or placebo. The primary endpoint was the development of persistent microalbuminuria. **Results**: The primary outcome was reached in 5.7% of combination patients, 6% of trandolapril patients, 11.9% of verapamil patients, and 10% of placebo patients. Serious adverse events were similar among all treatment groups. **Conclusions**: Treatment with ACEI trandolapril alone or trandolapril combined with verapamil decreased the incidence of microalbuminuria in patients with T2DM and HTN with normoalbuminuria.
DETAIL	NEJM 2004;351:1952-61	**Title**: Angiotensin-Receptor Blockade versus Converting–Enzyme Inhibition in Type 2 Diabetes and Nephropathy **Purpose**: Compare renoprotective effects of ARBs and ACEIs in patients with T2DM. **Methods**: 250 patients with T2DM and early nephropathy were randomized to either telmisartan 80 mg daily or enalapril 20 mg daily. The primary endpoint was a change in GFR between baseline and last available value, during the 5 yr study period. **Results**: At 5 yr, the change in GFR was -17.9 mL/min/1.73 m^2 with telmisartan, compared with 14.9 mL/min/1.73 m^2 with enalapril (difference -3.0 mL/min/1.73 m^2; 95% CI -7.6 to 1.6). **Conclusions**: The ARB telmisartan and the ACEI enalapril are equally effective in slowing renal function deterioration in T2DM with mild to moderate HTN and early nephropathy.
IDNT	NEJM 2001;345:851-60	**Title**: Renoprotective Effect of the Angiotensin-Receptor Antagonist Irbesartan in Patients with Nephropathy Due to Type 2 Diabetes **Purpose**: Assess whether the ARB irbesartan or the CCB amlodipine slow progression of nephropathy in patients with T2DM independently of BP effects. **Methods**: 1715 hypertensive patients with nephropathy due to T2DM were randomized to irbesartan 300 mg daily, amlodipine 10 mg daily, or placebo. The primary endpoint was a composite of the doubling of baseline serum Cr, development of ESRD, or all-cause mortality. **Results**: Treatment with irbesartan was associated with a rate of primary endpoints 20% lower than placebo ($P=0.02$) and 23% lower than amlodipine ($P=0.006$). Treatment with irbesartan was associated with a RR of ESRD 23% lower than that in both other groups ($P=0.07$ for both comparisons). These differences were not explained by BP changes. **Conclusions**: Treatment with irbesartan reduced the risk of developing ESRD and worsening renal function in patients with T2DM and diabetic nephropathy.

Trial Name	Reference	Clinical Trial Details
RENAAL	NEJM 2001;345:861-69	**Title**: Effects of Losartan on Renal and Cardiovascular Outcomes in Patients with Type 2 Diabetes and Nephropathy **Purpose**: Assess the role of ARB losartan in slowing progression of renal disease, in patients with T2DM and nephropathy. **Methods**: 1513 patients were randomized to losartan 50-100 mg daily or placebo, in addition to conventional antihypertensive treatments. The primary outcome was a composite of the doubling of serum Cr, ESRD, or mortality. **Results**: 327 patients in the losartan group, compared with 359 in the placebo group, achieved the primary endpoint (risk reduction 16%; P=0.02). Losartan reduced the incidence of the doubling of serum Cr (risk reduction 25%; P=0.006) and ESRD (risk reduction 28%; P=0.002), with no effect on mortality. **Conclusions**: Losartan conferred significant renal benefits in patients with T2DM and nephropathy, and was generally well-tolerated.
ROADMAP	NEJM 2011;364:907-17	**Title**: Olmesartan for the Delay or Prevention of Microalbuminuria in Type 2 Diabetes **Purpose**: Assess whether treatment with an ARB would prevent the occurrence of microalbuminuria in T2DM patients with normoalbuminuria. **Methods**: 4447 patients with T2DM were randomized to receive olmesartan 40 mg OD or placebo. Additional hypertensives were used as needed to meet the target BP of <130/80 mmHg. The primary outcome was the time until the first onset of microalbuminuria. **Results**: Microalbuminuria developed in 8.2% of olmesartan-treated patients, and 9.8% in the placebo group. The time to onset of this increase was increased by 23% with olmesartan (hazard ratio 0.77; 95% CI 0.63 to 0.94; P=0.01). **Conclusions**: The use of the ARB olmesartan was more effective than placebo in delaying the onset of microalbuminuria in patients with T2DM, normoalbuminuria, and good BP control.
VA-NEPHRON D	NEJM 2013; 369: 1892-903	**Title:** Combined Angiotensin Inhibition for the Treatment of Diabetic Nephropathy **Purpose:** To compare the safety and effectiveness of combining an ACE inhibitor and an ARB versus ARB monotherapy in proteinuric diabetic nephropathy progression. **Methods:** Patients with T2DM, urinary albumin-to-creatinine ratio ≥300, and estimated GFR of 30.0-89.9 ml/min/1.73 m^2 received losartan. They were then randomly assigned to lisinopril or placebo. The primary outcome was a decline in estimated GFR, ESRD, or death. The secondary outcome was a decline in estimated GFR or ESRD. Safety outcomes were also assessed. **Results:** The study was halted early due to safety concerns. Among 1448 patients with a median follow-up of 2.2 years, there was no significant difference in the primary endpoint between monotherapy and combination therapy groups. The trend towards a secondary endpoint benefit decreased over time. Combination therapy increased the risk of hyperkalemia and acute kidney injury. **Conclusions:** The combination of an ACE inhibitor and an ARB in patients with diabetic nephropathy was linked to higher adverse event risks.
PARENCHYMAL KIDNEY DISEASES		
AASK	JAMA 2001;285:2719-28	**Title**: Effect of Ramipril vs. Amlodipine on Renal Outcomes in Hypertensive Nephrosclerosis **Purpose**: Compare the effects of an ACEI, a dihydropyridine CCB and β-blocker on hypertensive renal disease progression. **Methods**: 1094 patients with hypertensive renal disease were randomized to amlodipine 5-10 mg/d, metoprolol 50-200 mg/d or ramipril 2.5-10 mg/d, with other agents. The primary outcome was the rate of change of GFR. **Results**: The ramipril group had a 36% slower mean decline in GFR (P=0.006) vs. the amlodipine group (95% CI 20% to 66%). There were no significant differences in the mean GFR decline from baseline to 3 yr between treatment groups. **Conclusions**: Ramipril, compared with amlodipine, slows progression of hypertensive renal disease and proteinuria, and may benefit patients without proteinuria as well.
AURORA 1	Lancet 2021; 397(10289): 2070-80	**Title**: Efficacy and safety of voclosporin versus placebo for lupus nephritis (AURORA 1): a double-blind, randomised, multicentre, placebo-controlled, phase 3 trial **Purpose**: Evaluate the safety and efficacy of voclosporin in the treatment of lupus nephritis. **Methods**: Adults diagnosed with systemic lupus erythematosus with lupus nephritis (biopsy class III-V) were randomized (1:1 ratio) to receive oral voclosporin or placebo, in addition to standard therapy. The primary outcome at wk 52 was a complete renal response (urine protein: Cr ratio ≤0.5 mg/mg, stable renal function (eGFR ≥60 mL/min/1.73 m2 or <20% decrease from baseline eGFR), and no rescue therapy). **Results**: At endpoint wk 52, significantly more patients in the voclosporin group had a complete renal response, as compared to the placebo group (41% vs. 23%; OR 2.65; 95% CI 11.64-4.27; P<0.0001). The adverse event profile was similar between groups (21% vs. 21%) with no deaths attributable to study-related treatments. **Conclusions**: Patients who received voclosporin in addition to standard therapy had a higher rate of complete renal response than those receiving standard therapy alone.
BLISS-LN	NEJM 2020;383:1117-28	**Title**: Two Year, Randomized, Controlled Trial of Belimumab in Lupus Nephritis **Purpose**: Elucidate the efficacy and safety of IV belimumab as compared with placebo, when added to standard therapy of mycophenolate mofetil or cyclophosphamide-azathioprine. **Methods**: Adults with biopsy-proven, active lupus nephritis were randomized (1:1 ratio) to receive IV belimumab (10 mg/kg) or matching placebo, in addition to standard therapy. The primary outcome at week 104 was a primary efficacy renal response (urinary protein: Cr ratio ≤0.7, eGFR no <20% pre-flare value, or ≥60 mL/min and no use of rescue therapy). **Results**: At endpoint wk104, significantly more patients in the belimumab group had a primary efficacy response, as compared to the placebo group (43% vs. 32%; OR 1.65; 95% CI 1.1 to 2.5; P=0.02). The risk of a renal-related event or death was lower among patients who received belimumab than placebo (hazard ratio 0.51; 95% CI 0.34 to 0.77; P=0.001). **Conclusions**: Patients who received belimumab in addition to standard therapy had a higher rate of primary efficacy response than those who received standard therapy alone.
CORAL	NEJM 2014;370:13-22	**Title**: Stenting and Medical Therapy for Atherosclerotic Renal-Artery Stenosis **Purpose**: Study the usefulness of renal artery stenting for the prevention of major adverse renal and CV events in patients with atherosclerotic renal artery stenosis. **Methods**: 947 patients with atherosclerotic renal artery stenosis and either systolic HTN or CKD were randomized to medical therapy plus stenting, or to medical therapy alone. The primary outcomes were occurrence of adverse CV and renal events. **Results**: The rate of primary events did not differ significantly between participants who underwent stenting or medical therapy alone (35.1% vs. 35.8%; hazard ratio 0.94; 95% CI 0.76 to 1.17; P=0.58). There were no significant differences in other components of the primary endpoint. **Conclusions**: Renal-artery stenting did not confer a significant benefit with respect to the prevention of renal or cardiac events when added to comprehensive, multifactorial medical therapy in people with atherosclerotic renal-artery stenosis and hypertension or chronic kidney disease.
MAINRITSAN	NEJM 2014;371:1771-80	**Title**: Rituximab versus Azathioprine for Maintenance in ANCA-Associated Vasculitis **Purpose**: Assess whether rituximab helps maintain remission of ANCA-associated vasculitis. **Methods**: Patients with newly diagnosed ANCA-associated vasculitides in complete remission were randomized to either rituximab 500 mg or daily azathioprine. The primary endpoint at 28 mo was the rate of major relapse. **Results**: At 28 mo, major relapse occurred in 29% of patients in the azathioprine group, compared to 5% of patients in the rituximab group (hazard ratio 6.61; 95% CI 1.56 to 27.96; P=0.002). The frequency of serious adverse events was comparable between groups. **Conclusions**: More patients with ANCA-associated vasculitis had sustained remission at 28 mo with rituximab than with azathioprine.

Trial Name	Reference	Clinical Trial Details
ONTARGET	Lancet 2008;372:547-53	**Title**: Renal Outcomes with Telmisartan, Ramipril, or Both, in People at High Vascular Risk **Purpose**: Investigate the renal effects of ACEI, ARB and combination, in patients with atherosclerotic vascular disease for the reduction of proteinuria. **Methods**: 25 620 patients were randomized to ramipril 10 mg daily, telmisartan 80 mg daily, or a combination. The primary renal outcome was a composite of dialysis, doubling of serum Cr, and mortality. **Results**: The number of primary events were similar for telmisartan (13.4%) and ramipril (13.5%), (hazard ratio 1.00; 95% CI 0.92 to 1.09) but were increased with combination therapy (14.5%; hazard ratio 1.09; 95% CI 1.01 to 1.18, P=0.037). **Conclusions**: Telmisartan and ramipril monotherapy reduced proteinuria and Cr increase in patients with high vascular risk.
PEXIVAS	NEJM 2020;382:622-31	**Title: Plasma Exchange and Glucocorticoids in Severe ANCA-Associated Vasculitis** **Purpose**: To assess the effectiveness of plasma exchange versus no plasma exchange in terms of mortality or ESRD in patients with severe ANCA-associated vasculitis. **Methods**: A randomized trial with 2-by-2 factorial design assessing plasma exchange and two oral glucocorticoid regimens in severe ANCA-associated vasculitis. The primary outcome was a composite of death or ESRD. The follow-up period was up to 7 years. **Results**: Death or ESRD rates were 28.4% in the plasma-exchange group and 31.0% in the control group, showing no significant difference. The reduced-dose glucocorticoid regimen was non-inferior to the standard-dose regimen for death or ESRD. The reduced-dose group had fewer serious infections, but other outcomes were similar between the groups. **Conclusions**: Plasma exchange did not reduce death or ESRD in severe ANCA-associated vasculitis. The reduced-dose glucocorticoid regimen was as effective as the standard dose.
REIN	Lancet 1999;354:359-64	**Title**: Renoprotective Properties of ACE-inhibition in Non-diabetic Nephropathies with Non-Nephrotic Proteinuria **Purpose**: Assess the renoprotective effects of ACE inhibition in non-diabetic nephropathies with non-nephrotic proteinuria. **Methods**: 186 patients were randomized to ramipril or control (placebo plus conventional antihypertensive). The primary endpoints were change in GFR and time to overt proteinuria. **Results**: The decline in monthly GFR was not significantly different (0.26 mL/min/1.73 m ²in ramipril group vs. 0.29 mL/min/1.73 m ²in the control group). Progression to ESRD was significantly less common with ramipril than control, for a RR of 2.72 (95% CI 1.22 to 6.08), likewise for progression to overt proteinuria (RR 2.40; 95% CI 1.27 to 4.52). **Conclusions**: In non-diabetic nephropathy, ACEI were renoprotective in patients with non-nephrotic range proteinuria.
REIN2	Lancet 2005;365:939-46	**Title**: Blood-Pressure Control for Renoprotection in Patients with Non-diabetic Chronic Renal Disease **Purpose**: Assess effects of intensified vs. conventional BP control with ACEI on progression to ESRD. **Methods**: Patients with non-diabetic nephropathies receiving background treatment were randomized to either conventional (diastolic <90 mmHg) or intensified (<130 mmHg) BP control. The primary outcome was time to ESRD over 36 mo. **Results**: Patients assigned to intensified BP control progressed to ESRD at a rate of 23% compared to 20% in the control group. **Conclusions**: In patients with non-diabetic nephropathy already on ACEI, there was no further benefit from intensified BP control by adding CCB vs. conventional BP control on ACEI alone.
ROAD	JASN 2007;18:1889-98	**Title**: Renoprotection of Optimal Antiproteinuric Doses **Purpose**: Determine whether titration of benazepril or losartan would improve renal outcomes in chronic renal insufficiency. **Methods**: 360 patients without DM, who had proteinuria and chronic renal insufficiency were randomized to benazepril 10 mg/d, benazepril 20 mg/d, losartan 50 mg/d, or losartan 100 mg/d. The primary endpoint was time to a composite of doubling serum Cr, ESRD, or mortality. **Results**: Up-titration of benazepril and losartan were associated with a 51% and 53% reduction in the primary endpoint risk (P=0.028 and 0.022 respectively). There was no significant difference in the rates of major adverse events between treatment groups. **Conclusions**: Up-titration of either ACEI benazepril or ARB losartan to optimal anti-proteinuria doses conferred benefit on renal outcome in patients without DM who had proteinuria and renal insufficiency.
AMACING	Lancet 2017;389:1312-22	**Title**: Prophylactic Hydration to Protect Renal Function from Intravascular Iodinated Contrast Material in Patients at High Risk of Contrast-Induced Nephropathy **Purpose**: Assess clinical effectiveness of prophylactic hydration in preventing contrast-induced nephropathy in patients with compromised renal function. **Methods**: High-risk adult patients undergoing an elective procedure requiring iodinated contrast were randomized to IV NaCl 0.9% or no prophylaxis. The primary outcome was incidence of contrast-induced nephropathy. **Results**: Contrast-induced nephropathy was recorded in 2.6% of non-hydrated patients and 2.7% of hydrated patients. **Conclusions**: No-hydration prophylaxis was non-inferior and cost-saving in preventing contrast-induced nephropathy compared with IV hydration.
CHRONIC KIDNEY DISEASE		
CHOIR	NEJM 2006;355:2085-98	**Title**: Correction of Anemia with Epoetin Alfa in Chronic Kidney Disease **Purpose**: Determine the optimal level of Hb correction in CKD with erythropoietin (EPO) deficiency as a complication. **Methods**: 1432 patients with CKD were randomized to receive epoetin alfa (human recombinant EPO) targeted to Hb 13.5 g/dL, or those receiving epoetin alfa targeted to Hb 11.3 g/dL. The primary endpoint was a composite of death, MI, hospitalization for CHF, and stroke. **Results**: 125 primary events occurred in the high-Hb group compared to 97 events in the low-Hb group (hazard ratio 1.34; 95% CI 1.03 to 1.74; P=0.03). More patients in the high-Hb group had at least one serious adverse event. **Conclusions**: A higher Hb correction target resulted in increased rates of infarction, hospitalization for CHF, and stroke.
CLICK	NEJM 2021; 385:2507-19	**Title**: Chlorthalidone for Hypertension in Advanced Chronic Kidney Disease **Purpose**: Understand the safety and efficacy of thiazide diuretic chlorthalidone for the treatment of HTN in patients with advanced CKD. **Methods**: 160 patients with stage 4 CKD and poorly controlled HTN were randomized (1:1 ratio) to receive chlorthalidone or placebo. The primary outcome measure was the change in 24-h ambulatory sBP from baseline to 12 wk post-treatment. **Results**: Patients with advanced CKD and poorly controlled CKD receiving chlorthalidone experienced a greater reduction in sBP than those receiving placebo therapy (-11.0 mmHg vs. -0.5 mmHg; P<0.001). Adverse events, including hypokalemia, hyperglycemia, dizziness, and hyperuricemia occurred more frequently in patients receiving chlorthalidone. **Conclusions** : In patients with advanced CKD and poorly controlled HTN, chlorthalidone more effectively reduces sBP than placebo, however, adverse events must be carefully considered.
CREATE	NEJM 2006;355:2071-84	**Title**: Normalization of Hemoglobin Level in Patients with Chronic Kidney Disease and Anemia **Purpose**: Establish whether correction of anemia in stage 3 or 4 CKD improves CV outcomes. **Methods**: 603 patients with eGFR 15.0 to 35.0 mL/min/1.73 m2 and mild-moderate anemia were randomized to a normal target Hb (13-15 g/dL) or a subnormal target range (10.5-11.5 g/dL). The primary endpoint was a composite of 8 CV events. **Results**: Complete correction of anemia did not affect the likelihood of a first CV event (hazard ratio 0.78; 95% CI 0.53 to 1.14; P=0.20). The mean eGFR was 24.9 mL/min/1.73 m²in the complete group, and 24.2 mL/min/1.73 m2 in the incomplete group, decreasing by 3.6 and 3.1 mL/min/1.73 m²/yr, respectively. **Conclusions**: In patients with CKD, complete correction of Hb did not reduce the risk of CV events or incidence of hypertensive episodes.

Trial Name	Reference	Clinical Trial Details
CREDENCE	NEJM 2019;380:2295-306	**Title**: Canagliflozin and Renal Outcomes in Type 2 Diabetes and Nephropathy (CREDENCE) **Purpose**: Since few effective treatments are available for diabetic nephropathy, this study aims to assess renal outcomes in patients treated with SGLT2 inhibitor canagliflozin. **Methods**: Patients with type 2 diabetes and albuminuric CKD were randomized to receive canagliflozin 100 mg daily, or placebo. All patients had an estimated GFR of 30 to <90 mL/min/1.73 $m^2$and albuminuria >300 to 5000, and were treated with RAAS blockade. The primary outcome was a composite of ESRD (dialysis, transplantation, or sustained eGFR <15mL/min/1.73 m^2), a doubling of serum Cr, or death from renal or CV (CV) causes. **Results**: Of 4401 randomized patients with a median follow-up of 2.62 yr, the RR of primary outcome was 30% lower in the canagliflozin group than in the placebo group (hazard ratio 0.70; 95% CI 0.59 to 0.82; P=0.00001). The canagliflozin group also had a lower risk of CV death, MI or stroke (hazard ratio 0.85; 95% CI 0.67 to 0.95; P=0.01). **Conclusions**: In patients with T2DM and kidney disease, the risk of kidney failure and CV events was lower in the canagliflozin group than in the placebo group.
DAPA-CKD	NEJM 2020; 383:1436-46	**Title**: Dapagliflozin in Patients with Chronic Kidney Disease **Purpose**: Elucidate the safety of dapagliflozin in patients with CKD with or without T2DM. Methods: 4304 patients with CKD (eGFR 25-73 mL/min/1.73 $m^2$and ACR 200-5000) were randomized to receive dapagliflozin or placebo. The **Methods** outcome was a composite of ≥50% reduction in eGFR, ESRD, and death from cardiorenal causes. Results: The primary outcome occurred less frequently in patients receiving dapagliflozin compared to those receiving placebo (9,2% vs. 14.5%; HR 0.61; 95% CI 0.51-0.72; P<0.001; NNT to prevent one primary outcome event 19; 95% CI 15-27). This trial was stopped early because of efficacy. **Conclusions**: Patients receiving dapagliflozin are less likely to experience a composite of ≥50% reduction in eGFR, ESRD, or death from cardiorenal causes compared to those receiving placebo. Dapagliflozin is safe in patients with CKD.
EMPA-CKD	NEJM 2023;388:117–27	**Title**: Empagliflozin in Patients with Chronic Kidney Disease **Purpose**: To evaluate the impact of empagliflozin on patients with CKD who are at risk of disease progression, encompassing a wide range of individuals. **Methods**: 6609 participants were randomly assigned to receive empagliflozin (10mg once daily) or placebo. Participants had CKD with different levels of kidney function. The primary outcome assessed kidney disease progression or cardiovascular-related death. **Results**: During a median 2.0 years of follow-up, the empagliflozin group (13.1%) had a lower occurrence of primary outcome events compared to the placebo group (16.9%). There were fewer hospitalizations in the empagliflozin group, but no significant effect on heart failure or cardiovascular death. Rates of serious adverse events were similar. **Conclusions**: Empagliflozin decreased the risk of kidney disease progression or cardiovascular death in a broad range of patients at risk of CKD progression.
FIDELIO-DKD	NEJM 2020;383:2219-29.	**Title**: Effect of Finerenone on Chronic Kidney Disease Outcomes in Type 2 Diabetes **Purpose**: Understand the effects of finerenone on kidney and cardiovascular outcomes in patients with CKD and T2DM. Methods: 5734 patients with CKD (diabetic retinopathy + urine ACR 30-300 + eGFR 25-60 mL/min/1.73 m^2or urine ACR 300-5000 + eGFR 25-75 mL/min/1.73 m2) and T2DM were randomized (1:1 ratio) to receive finerenone or placebo. The primary outcome measure was a composite of kidney failure, ≥40% reduction in eGFR, and death from renal causes. Results: The primary outcome occurred less frequently in patients receiving finerenone compared to those receiving placebo (17.8% vs. 21.1%; HR 0.82; 95% CI 0.73-0.93; P=0.001). The frequency of adverse events was comparable between groups, though hyperkalemia-related discontinuation of therapy occurred more frequently in patients receiving finerenone. **Conclusions**: Patients receiving finerenone are less likely to experience a composite of kidney failure, ≥40% reduction in eGFR, and death from renal causes compared to those receiving placebo.
SHARP	Lancet 2011;377:2181-92	**Title**: The Effects of Lowering LDL Cholesterol with Simvastatin plus Ezetimibe in Patients with Chronic Kidney Disease **Purpose**: Assess safety and efficacy of low-density lipoprotein (LDL)-lowering with simvastatin plus ezetimibe in patients with CKD. **Methods**: 9270 patients with moderate-severe CKD with no history of MI or coronary revascularization were randomized to simvastatin 20 mg plus ezetimibe 10 mg daily, or to matching placebo. The primary outcome was the first major atherosclerotic event. **Results**: Combination therapy resulted in a 17% reduction in first major atherosclerotic events (11.3% vs. 13.4%; RR 0.83; 95% CI 0.74 to 0.94; P=0.0021). There were significant reductions in non-hemorrhagic strokes (2.8% vs. 3.8%; RR 0.75; 95% CI 0.60 to 0.94; P=0.01) and arterial revascularization (6.1% vs. 7.6%; RR 0.79; 95% CI 0.68 to 0.93; P=0.0036). **Conclusions**: In patients with CKD and no history of MI or coronary revascularization, 20 mg simvastatin plus 10 mg ezetimibe daily, compared to matching placebo, reduced the incidence of major atherosclerotic events.
SPRINT	NEJM 2015; 373:2103-16	**Title**: A Randomized Trial of Intensive versus Standard Blood-Pressure Control **Purpose**: To compare the effectiveness of treating systolic blood pressure to a target below 120 mmHg versus treating it to a target below 140 mmHg. **Methods**: A randomized trial including 9361 individuals with elevated cardiovascular risk without diabetes were assigned to either an intensive (target <120 mmHg) or standard (target <140 mmHg) systolic blood pressure treatment. The primary outcome included various cardiovascular events. **Results**: After 1 year, the intensive-treatment group achieved a lower mean systolic blood pressure of 121.4 mmHg compared to 136.2 mmHg in the standard-treatment group. The trial was stopped early due to significantly lower rates of the primary composite outcome and all-cause mortality in the intensive-treatment group. However, the intensive-treatment group experienced higher rates of certain serious adverse events. **Conclusions**: Targeting a systolic blood pressure below 120 mm Hg in high-risk, non-diabetic patients reduced cardiovascular events but increased some adverse events.
TEMPO 3:4	NEJM 2012;367:2407-18	**Title**: Tolvaptan in Patients with Autosomal Dominant Polycystic Kidney Disease **Purpose**: To determine the annual rate of change in the total kidney volume. **Methods**: 1445 Autosomal Dominant Polycystic Kidney Disease (ADPKD) patients aged 18-50 randomly assigned 2:1 to receive tolvaptan or placebo in Phase 3 double-blind, multicenter, and placebo-controlled trial lasting 3 years. The primary endpoint was annual rate of change in total kidney volume. Secondary endpoints included a composite of clinical progression and rate of kidney-function decline. **Results**: Over a 3-year period, tolvaptan resulted in a slower increase in total kidney volume (2.8% per year) compared to placebo (5.5% per year). Tolvaptan showed better outcomes in the composite endpoint, with lower rates of worsening kidney function, kidney pain, and a slower decline in kidney function. Tolvaptan had fewer ADPKD-related adverse events but more discontinuations due to aquaresis and hepatic issues. **Conclusions**: Tolvaptan slowed kidney volume increase and function decline but had higher discontinuation rates due to adverse events in ADPKD.
TREAT	NEJM 2009;361:2019-32	**Title**: A Trial of Darbepoetin Alfa in Type 2 Diabetes and Chronic Kidney Disease **Purpose**: Assess clinical outcomes with darbepoetin alfa among patients with T2DM and CKD. **Methods**: 4038 patients with diabetes, CKD and anemia were randomized to darbepoetin alfa at 13 g/dL, or to placebo. The primary endpoints were the composite outcomes of death, CV event, death, or ESRD. **Results**: Death or CV events occurred in 632 patients treated with darbepoetin alfa and 602 placebo-matched patients (hazard ratio 1.05; 95% CI 0.94 to 1.17; P=0.41). Death or ESRD occurred in 652 patients treated with darbepoetin alfa and 618 placebo-matched patients (hazard ratio 1.06; 95% CI 0.95 to 1.19; P=0.29). **Conclusions**: Darbepoetin alfa did not reduce the risk of death, a CV event, or a renal event, and was associated with an increased risk of stroke.

Trial Name	Reference	Clinical Trial Details
EVOLVE	NEJM 2012; 367:2482-94	**Title**: Effect of Cinacalcet on Cardiovascular Disease in Patients Undergoing Dialysis **Purpose**: Assess the effects of calcimimetic agent cinacalcet in reducing mortality risk and nonfatal CV events in patients with CKD. **Methods**: 3383 patients with moderate-severe hyperparathyroidism undergoing hemodialysis were randomized to cinacalcet or placebo. The primary composite endpoint was time until death, MI, hospitalization for unstable angina (UA), HF, or a peripheral vascular event. **Results**: The primary endpoint was reached in 48.3% of cinacalcet-treated patients and 49.2% of placebo-matched patients (hazard ratio 0.93; 95% CI 0.85 to 1.02; P=0.11). **Conclusions**: Cinacalcet did not significantly reduce the risk of death or major CV events in patients with moderate-to-severe secondary hyperparathyroidism who were undergoing dialysis.
CYSTIC DISEASES OF THE KIDNEY		
REPRISE	NEJM 2017;377:1930-42	**Title**: Tolvaptan in Later-Stage Autosomal Dominant Polycystic Kidney Disease **Purpose**: Assess the efficacy and safety of tolvaptan in patients with later-stage autosomal dominant polycystic kidney disease (ADPCKD). **Methods**: 1370 patients with ADPCKD with eGFR 25 to 44 mL/min/1.73 m^2were randomized (1:1 ratio) to tolvaptan or placebo for 12 mo. The primary endpoint was a change in eGFR from baseline to follow-up. **Results**: The change from baseline eGFR was -2.34 mL/min/1.73 m^2in the tolvaptan group (95% CI -2.81 to -1.87) compared with -3.61 mL/min/1.73 m2 in the placebo group (95% CI -4.08 to -3.14); (difference 1.27; 95% CI 0.86 to 1.86; P<0.001). **Conclusions**: Tolvaptan treatment in patients with later-stage ADPKD resulted in a slower decline in eGFR over a 1 yr period, compared to the placebo group.
RENAL REPLACEMENT THERAPY		
ALERT	Lancet 2003;361:2024-31	**Title**: Effect of Fluvastatin on Cardiac Outcomes in Renal Transplant Recipients **Purpose**: Evaluate the safety and efficacy of fluvastatin on cardiac and renal endpoints in renal transplant recipients. **Methods**: 2102 renal transplant patients were randomized to fluvastatin or placebo. The primary endpoint was the occurrence of a major CV event, including cardiac death, nonfatal MI, or coronary intervention. **Results**: Risk reduction in primary events was not significant with fluvastatin (risk ratio 0.83; 95% CI 0.64 to 1.06; P=0.139). There were fewer cardiac deaths and nonfatal MI in the fluvastatin group than in the placebo group (risk ratio 0.60; 95% CI 0.48 to 0.88; P=0.005). **Conclusions**: The use of fluvastatin in renal transplant recipients did not significantly decrease the risk of occurrence of a major adverse cardiac event, however, there was a significant reduction in cardiac deaths or nonfatal MI.
AURORA	NEJM 2009;360:1395-407	**Title**: Rosuvastatin and Cardiovascular Events in Patients Undergoing Hemodialysis **Purpose**: Assess the benefit of statin therapy in patients undergoing hemodialysis for reduction of CV risk. **Methods**: 2776 patients undergoing maintenance hemodialysis were randomized to rosuvastatin 10 mg daily or placebo. The primary endpoint was death from CV causes, nonfatal MI, or stroke. **Results**: 9.2% and 9.5% of patients reached the primary endpoint, in the rosuvastatin and placebo groups, respectively (hazard ratio 0.96; 95% CI 0.84 to 1.11; P=0.59). Rosuvastatin had no effect on individual components of the primary endpoint. **Conclusions**: In patients receiving maintenance hemodialysis, rosuvastatin had no significant effect on CV risk.
ELITE-SYMPHONY	NEJM 2007;357:2562-75	**Title**: Reduced Exposure to Calcineurin Inhibitors in Renal Transplantation **Purpose**: Evaluate the efficacy and relative toxic effects of four immunosuppressive agents in renal transplant recipients. **Methods**: 1645 renal-transplant recipients were randomized to receive standard-dose cyclosporine plus mycophenolate mofetil plus corticosteroids, or daclizumab induction plus mycophenolate mofetil plus corticosteroids, both groups in combination with either low-dose cyclosporine, low-dose tacrolimus, or low-dose sirolimus. The primary endpoint was eGFR 12 mo after transplantation. **Results**: The mean eGFR was higher in patients receiving low-dose tacrolimus (65.4 mL/min/1.73 m^2) than in the 3 other groups (ranging from 56.7 mL/min/1.73 $m^2$to 59.5 mL/min/1.73 m^2). Serious adverse events were more common in low dose sirolimus than the other groups (53.2% vs. a range of 43.4% to 44.3%). **Conclusions**: Daclizumab induction, mycophenolate mofetil, corticosteroids, and low-dose tacrolimus effectively maintain stable renal function following renal transplantation, without the negative effects on renal function commonly reported for standard calcineurin inhibitor (CNI) regimens.
FHN	NEJM 2010;363:2287-300	**Title**: Hemodialysis Six Times per Week versus Three Times per Week **Purpose**: Determine whether increasing the frequency of in-center hemodialysis would be beneficial. **Methods**: Patients were randomized to undergo hemodialysis 6x/wk or 3x/wk. The primary composite outcomes were death or change in left ventricular (LV) mass, and death or change in physical health scores. **Results**: Frequent hemodialysis was associated with significant benefits with respect to both primary outcomes (hazard ratio for LV mass 0.61; 95% CI 0.46 to 0.83; hazard ratio for physical health 0.70; 95% CI 0.53 to 0.92). Frequent hemodialysis was also associated with improved HTN and hyperphosphatemia control. **Conclusions**: Frequent hemodialysis, versus conventional hemodialysis, is associated with favourable patient outcomes.
HEMO	NEJM 2002;347:2010-19	**Title**: Effect of Dialysis Dose and Membrane Flux in Maintenance Hemodialysis **Purpose**: Assess the effects on morbidity and mortality of dialysis dose and level of flux, in patients undergoing maintenance hemodialysis. **Methods**: 1846 patients undergoing thrice-weekly dialysis were randomized to high-dose dialysis and to a low- or high-flux dialyzer. The primary outcome was all-cause mortality. **Results**: The primary outcome was not influenced by the dose or flux assignment; (RR 0.96; 95% CI 0.84 to 1.10; P=0.53) for a comparison of the high-dose group with standard-dose, and (RR 0.96; 95% CI 0.81 to 1.05; P=0.23) for a comparison of high- and low-flux dialyzer assignments. **Conclusions**: Use of high dose dialysis or high flux membranes vs. standard dose or low flux in 3x/wk dialysis does not improve survival or outcomes.
IDEAL	NEJM 2010;363:609-19	**Title**: A Randomized, Controlled Trial of Early versus Late Initiation of Dialysis **Purpose**: Examine effects of timing dialysis initiation on survival in patients with CKD. **Methods**: Patients with CKD and eGFR 10 to 15 mL/min/1.73 m2 were randomized to early initiation (eGFR 10.0 to 14.0 mL/min/1.73 m^2) or late initiation (eGFR 5.0 to 7.0 mL/min/1.73 m2). The primary outcome was all-cause mortality. **Results**: A total of 37.6% of patients in the early initiation group and 36.6% of patients in the late-initiation group died within 3.59 yr (hazard ratio 1.04; 95% CI 0.83 to 1.30; P=0.75). There were no significant differences in the frequency of adverse events. **Conclusions**: In patients with progressive CKD, early initiation of dialysis was not associated with an improvement in survival or clinical outcomes.
CONVERT	Transplantation 2009;87:233-42	**Title**: Conversion from Calcineurin Inhibitors to Sirolimus Maintenance Therapy in Renal Allograft Recipients **Purpose**: Evaluate the efficacy and safety of converting maintenance renal transplant patients from CNIs to sirolimus. **Methods**: 830 renal allograft recipients were randomized to continue CNI or convert from CNI to sirolimus. Primary endpoints were GFR and the rates of biopsy-confirmed acute rejection (BCAR), graft loss, or death at 12 mo. **Results**: Intention-to-treat analysis showed no significant difference in GFR, while on-therapy analysis showed higher GFR at 12 and 24 mo after sirolimus conversion. Rates of other primary endpoints were similar between groups. Malignancy rates were significantly lower at 12 and 24 mo in patients who underwent sirolimus conversion. **Conclusions**: At 2 years, conversion of maintenance therapy in renal transplant patients from CNIs to sirolimus was associated with excellent patient and graft survival.

Trial Name	Reference	Clinical Trial Details
STARRT-AKI	NEJM 2020;383:240–51	**Title**: Timing of Initiation of Renal-Replacement Therapy in Acute Kidney Injury **Purpose**: To evaluate and compare the impact of two strategies (accelerated initiation versus standard initiation) on critically ill patients with AKI. **Methods**: A multinational trial randomized critically ill patients with severe AKI to receive either accelerated or standard initiation of renal-replacement therapy, with the primary outcome as 90-day all-cause mortality. **Results**: Of 3019 patients, 97% were included in the analysis. The accelerated-strategy group had higher rates of renal-replacement therapy and adverse events. However, there was no significant difference in 90-day mortality between the accelerated and standard strategy groups. Survivors in the accelerated-strategy group had a higher dependence on renal-replacement therapy. **Conclusions**: The use of an accelerated renal-replacement strategy did not result in a lower 90-day mortality risk in critically ill patients with AKI.

TCA	tricyclic antidepressant
TIA	transient ischemic attack
tPA	tissue plasminogen activator
UMN	upper motor neuron

Lesion Localization

- **CNS vs. PNS lesion**
  - CNS: cortical, subcortical, brainstem (midbrain, pons, medulla), cerebellum, spinal cord
  - PNS: nerve root, plexus, peripheral nerve, neuromuscular junction, muscle
  - see *Table 3, N4* for differentiating LMN, UMN and extrapyramidal lesions
- **cortical**
  - contralateral hemiparesis (with differential effect on face and arm vs. leg)
  - contralateral hemisensory loss, cortical sensory loss (graphesthesia, stereognosis)
  - dominant hemisphere: aphasia, alexia, agraphia, acalculia, left-right disorientation
  - non-dominant hemisphere: hemineglect, dysprosody, amusia, constructional apraxia, alien hand syndrome
  - homonymous hemianospia/quadrantanospia
  - gaze deviation (involvement of frontal eye field)
  - seizure
  - agnosia (visual, auditory)
  - ideomotor and ideational apraxia
- **subcortical**
  - internal capsule: contralateral hemiparesis with equal face, arm, and leg involvement without sensory/cortical deficits (pure motor); contralateral hemiparesis and sensory deficit (sensorimotor); contralateral dysmetria/clumsiness and paresis (ataxic hemiparesis); dysarthria and ataxia of the hand (clumsy hand-dysarthria syndrome)
  - basal ganglia: resting tremor, bradykinesia, festinating gait, hemiballism, chorea, dystonic posture
  - thalamus: dense sensory loss, contralateral severe pain, visual field defect, cognitive impairment, altered LOC
- **brainstem (midbrain, pons, medulla)**
  - crossed hemiplegia or hemisensory loss (i.e. ipsilateral face, contralateral body)
  - ipsilateral limb ataxia (dysmetria, impaired rapid alternating movements)
  - nystagmus, diplopia, ptosis, pupil abnormalities (miosis, mydriasis), gaze impairment, internuclear ophthalmoplegia
  - dysphagia, dysarthria
  - hearing loss, vertigo
  - ipsilateral Horner's syndrome
- **cerebellum**
  - symptoms ipsilateral to side of lesion
  - limb ataxia (dysmetria, intention tremor, dysdiadochokinesia, hypotonia causing pendular reflexes)
  - truncal ataxia (wide-based gait, inability to perform heel-to-toe gait, truncal titubation)
  - nystagmus, hypermetric or hypometric saccades, impaired smooth pursuit
  - scanning speech (explosive speech with noticeable pauses and accentuated syllables)
- **spinal cord**
  - LMN signs at level of lesion; UMN signs below level of lesion
  - sensory level (line below which there is sensory loss); suspended "cape-like" sensory level (in central cord lesions)
  - neurogenic bladder and bowel, sexual dysfunction
  - saddle anesthesia (involvement of conus medullaris)
  - sensory ataxia (involvement of dorsal columns)
- **nerve root**
  - multiple peripheral nerve involvement
  - myotomal/dermatomal deficits
  - back/neck pain radiating to limb
  - saddle anesthesia (involvement of cauda equina)

- **peripheral nerve**
  - length-dependent ("stocking-glove distribution") or non-length-dependent sensory loss (see *Peripheral Neuropathies, N38*)
  - weakness or sensory loss respecting the distribution of a specific nerve (e.g. median nerve, ulnar nerve, radial nerve)
- **neuromuscular junction**
  - fluctuating/fatigable symptoms
  - facial and limb weakness, bulbar (dysarthria, dysphonia, dysphagia), ocular (diplopia, ptosis), respiratory distress (see *Neuromuscular Diseases, N40*)
  - reflexes usually preserved unless severe/advanced or LEMS
- **muscle**
  - usually symmetric proximal weakness (e.g. climbing stairs, getting up from chair) without sensory deficits
  - asymmetric myopathic weakness seen in distal myopathies, myositis, glycogen storage diseases, and facioscapulohumeral dystrophy
  - myalgia, muscle atrophy

Neurological Exam

Mental Status Exam

- orientation (person, place, time)
- appearance, mood and affect
- language, attention (serial sevens, months backwards)
- LOC with GCS
  - score from 3-15 (eye opening/4, verbal response/5, motor response/6)
- memory
  - MMSE – /30 (normal: ≥24, mild impairment: 19-23, moderate impairment: 10-18, severe impairment: <10)
  - MoCA – /30 (normal: ≥26)

Table 1. Glasgow Coma Scale

Points	Eyes	Verbal	Motor
1	No eye opening	No verbal response	No motor response
2	Eye opening to pain	Incomprehensible sounds	Extension to pain
3	Eye opening to verbal stimulus	Inappropriate words	Flexion to pain
4	Eye opening spontaneously	Confused	Withdraws from pain
5		Oriented	Localizes pain
6			Obeys commands

Screening Neurologic Exam
Mental status: orientation (person, place, time), obeys commands, gcs
Cranial nerves: visual acuity, visual fields, pupils, eye movements, face sensation, muscles of facial expression, speech, swallowing, sternocleidomastoid, trapezius, tongue
Motor: tone, power, reflexes (biceps, triceps, patellar, ankle), special tests (plantar response, pronator drift)
Sensory: pain, temperature, vibration, proprioception
Coordination: finger-to-nose, heel-to-shin, rapid alternating movements
Gait: normal, heel-to-toe, pull test

Cranial Nerve Exam

Table 2. Cranial Nerve Exam and Associated Deficits

Cranial Nerve	Physical Exam	Deficit
Olfactory (CN I)	Test identification of common odorants (i.e. coffee) in each nostril	Anosmia (complete loss of smell), hyposmia (partial loss of smell)
Optic (CN II)	Visual acuity, visual fields, colour vision, Pupils: symmetry, direct and consensual pupillary-light reflex, swinging flashlight test for RAPD Fundoscopy	Vision loss, absence of pupillary-light reflex, RAPD, optic disc edema/pallor
Oculomotor (CN III)	Test eye movements Pupils: symmetry, direct and consensual pupillary-light reflex Observe eyelids	Oblique binocular diplopia, eye position "down and out," mydriasis, ptosis
Trochlear (CN IV)	Test eye movements (superior oblique performs intorsion, depression and abduction of eye)	Vertical binocular diplopia, hypertropia, contralateral head tilt
Trigeminal (CN V)	Test face sensation: V1 (forehead, corneal reflex), V2 (cheek), V3 (chin) Test muscles of mastication: palpate temporalis and masseter when jaw clenched, observe for jaw deviation on mouth opening, test jaw jerk reflex	Decreased facial sensation, absent corneal reflex, atrophy and weakness of muscles of mastication, jaw deviation to weak side
Abducens (CN VI)	Test eye movements (lateral rectus performs abduction of eye)	Horizontal binocular diplopia, abduction deficit, esotropia
Facial (CN VII)	Test muscles of facial expression (raise eyebrows, close eyes tightly, smile with teeth showing) Test corneal reflex (efferent limb) Test taste in anterior 2/3 of tongue	Unilateral facial weakness (ipsilateral to LMN lesion, contralateral with forehead sparing in UMN lesion), decreased lacrimation, decreased salivation, hyperacusis, loss of taste from anterior 2/3 of tongue

If patient has not brought their glasses, have them look through a pinhole for best corrected vision

Innervation of Extraocular Muscles
CN III: superior rectus, inferior rectus, medial rectus, inferior oblique
CN IV: superior oblique
CN VI: lateral rectus

Contraction of the left sternocleidomastoid turns the head right

Table 2. Cranial Nerve Exam and Associated Deficits

Cranial Nerve	Physical Exam	Deficit
Vestibulocochlear (CN VIII)	Hearing: whisper, Rhinne and Weber tests Vestibular function: observe for nystagmus during eye movements, caloric test	Hearing loss, vertigo, nystagmus
Glossopharyngeal (CN IX)	Test swallowing, test gag reflex (afferent limb), test taste in posterior 1/3 of tongue	Mild oropharyngeal dysphagia, absent gag reflex, loss of taste from posterior 1/3 of tongue
Vagus (CN X)	Ask patient to open mouth, observe for soft palate and uvula, test swallowing, listen to speech for vocal cord function, test gag reflex (efferent limb)	Oropharyngeal dysphagia, hoarseness, dysarthria, soft palate drooping, contralateral uvula deviation, vocal cord paralysis, absent gag reflex
Accessory (CN XI)	Test strength of sternocleidomastoid (head turn) Test strength of trapezius (shoulder shrug)	Ipsilateral shoulder shrug weakness Contralateral head turn weakness
Hypoglossal (CN XII)	Ask patient to stick out tongue Inspect for deviation, atrophy and fasciculations Test strength through cheek	Tongue deviation to weak side on protrusion, atrophy, fasciculations

Caloric Test
Uses vestibulo-ocular reflex to test vestibular function
Cold fluid causes nystagmus towards contralateral ear
Warm fluid causes nystagmus towards ipsilateral ear

COWS: cold opposite, warm same

Motor Exam

- inspection
  - muscle bulk: atrophy, hypertrophy, asymmetry
  - abnormal movements: tremor, chorea, dystonia, dyskinesia, hemiballism, myoclonus, athetosis, tics, fasciculations, myokymia
  - abnormal posturing: flexor/decorticate (upper limb flexion and lower limb extension), extensor/decerebrate (limb extension)
- muscle tone
  - passively move a joint (i.e. elbow, wrist) and feel for resistance
  - hypotonia, hypertonia (spasticity, rigidity, paratonia)
- muscle power
- reflexes
  - upper limb reflexes (biceps, triceps, brachioradialis)
  - lower limb reflexes (patellar, ankle)
  - pathological reflexes (clonus, plantar response, Hoffmann's reflex)
- special tests (pronator drift, Holmes rebound phenomenon)

UMN Tests
Plantar response: normal is a flexor plantar response, abnormal is an extensor plantar response (Babinski sign) involving big toe extension
Pronator drift: with upper limbs extended in front, unable to keep them supinated with eyes closed
Hoffmann's reflex: flicking nail of middle finger causes reflexive flexion of thumb

Table 3. Differentiating LMN, UMN and Extrapyramidal Lesions

	LMN	UMN	Extrapyramidal
Muscle Tone	Hypotonia	Spasticity (hypertonia that is velocity-dependent)	Rigidity (hypertonia that is not velocity-dependent)
Muscle Atrophy	Significant denervation atrophy	Disuse atrophy over time	Variable
Reflexes	Decreased (hyporeflexia or areflexia)	Increased (hyperreflexia)	Variable
Plantar Reflex	Flexor plantar response	Extensor plantar response (Babinski sign)	Flexor plantar response
Involuntary Movements	Fasciculations	None	Tremor, chorea, hemiballism, myoclonus

Muscle Power Grading	
5	Normal power
4	Movement against gravity with some resistance (range 4-, 4, 4+)
3	Movement against gravity only
2	Movement with gravity eliminated
1	Flicker of contraction
0	No muscle contraction

Table 4. Overview of Neuromuscular Diseases

	Motor Neuron Disease (e.g. ALS)	Peripheral Neuropathy	Neuromuscular Junction Disorder	Myopathy
Signs and Symptoms				
Weakness	Segmental and asymmetrical, distal to proximal	Distal (except GBS) usually symmetrical	Proximal and fatigable (e.g. MG), or weak then recovers (e.g. LEMS)	Proximal (with some exceptions)
Fasciculations	Yes	Yes	No	No
Reflexes	Mixture of hyperreflexia and hyporeflexia or areflexia	Hyporeflexia or areflexia	Normal	Normal (until late)
Sensory	No	Yes	No	No
Autonomic	No	Yes	No (except LEMS)	No
Tests				
EMG	Denervation and reinnervation	Signs of demyelination and/or axonal loss	Decremental response on repetitive nerve stimulation, jitter on single fibre EMG	Small, short motor potentials
NCS	Normal or abnormal	Abnormal	Normal	Normal
Creatine Kinase	Normal or mildly increased	Normal	Normal	Increased (early/mid-stage) Normal/decreased (late stage)

Reflex	Muscle	Spinal Nerve	Peripheral Nerve
Biceps reflex	Biceps brachii	C5, C6	Musculocutaneous nerve
Triceps reflex	Triceps brachii	C7	Radial nerve
Brachioradialis reflex	Brachioradialis	C5, C6	Radial nerve
Patellar (knee) reflex	Quadriceps femoris	L2, L3, L4	Femoral nerve
Ankle (Achilles) reflex	Gastrocnemius and soleus	S1, S2	Tibial nerve
L2/3			Hip adductors
L3/4			Knee extensors
S1/2			Ankle (Achilles)

Reflex Grading	
0	Absent (areflexia)
1+	Decreased (hyporeflexia)
2+	Normal
3+	Increased (hyperreflexia)
4+	Increased with clonus (≥4 beats)

Table 5. Differentiating Radiculopathies and Peripheral Neuropathies

For each spinal nerve, learn two or more peripheral nerves and their associated actions/muscles.
In radiculopathies, all associated peripheral nerves (and their actions) will be impaired, whereas in peripheral neuropathies, only one of the nerves (and its actions) will be impaired.

Spinal Nerve	Peripheral Nerve	Action	Muscle
C5	Axillary	Shoulder abduction	Deltoid
C6	Musculocutaneous	Elbow flexion	Biceps brachii
	Radial	Wrist extension	Extensor carpi radialis longus
C7	Radial	Elbow extension	Triceps brachii
	Posterior interosseous	Finger extension	Extensor digitorum
	Median	Forearm pronation	Pronator teres
		Wrist flexion	Flexor carpi radialis
C8, T1	Median	Thumb flexion	Flexor pollicis longus
		Thumb abduction	Abductor pollicis brevis
		Opposition	Opponens pollicis
	Ulnar	Finger abduction	Dorsal interossei
	Radial	Index finger extension	Extensor indicis proprius
L2, L3, L4	Femoral	Hip flexion	Iliopsoas
		Knee extension	Quadriceps femoris
	Obturator	Hip adduction	Hip adductors
	Superior gluteal	Hip abduction	Tensor fasciae latae
L5	Tibial	Knee flexion	Hamstrings
		Ankle inversion	Tibialis posterior
	Superficial peroneal	Ankle eversion	Peroneus longus and brevis
	Deep peroneal	Ankle dorsiflexion	Tibialis anterior
		Big toe extension	Extensor hallucis longus
	Inferior gluteal nerve	Hip extension	Gluteus maximus
S1, S2	Tibial nerve	Ankle plantarflexion	Gastrocnemius and soleus

Cerebellar Signs and Symptoms
Limb ataxia: dysmetria, intention tremor, dysdiadochokinesia, hypotonia causing pendular reflexes, Holmes rebound phenomenon (if involvement of lateral zone of cerebellar hemisphere)
Truncal ataxia: wide-based gait and inability to perform heel-to-toe gait (if involvement of cerebellar vermis)
Eyes: nystagmus, hypermetric or hypometric saccades, impaired smooth pursuit
Speech: scanning speech

Romberg Test
Stable with eyes closed: normal
Unstable with eyes closed: positive Rhomberg, may indicate loss of proprioception
Sensory Exam

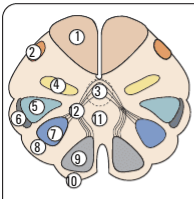
Sensory Exam

- **primary sensory modalities**
  - spinothalamic tract: pain and temperature
  - dorsal column-medial lemniscus pathway: fine touch, vibration, proprioception
- **cortical sensation**
  - graphesthesia, stereognosis, tactile extinction, 2-point discrimination
  - deficits in cortical sensation are often localized to the contralateral parietal lobe
- **Romberg test**
  - patient stands with eyes closed and feet together
  - instability may indicate loss of proprioception causing sensory ataxia

Coordination and Gait Exam

- **upper limb coordination**
  - finger-to-nose test
  - rapid alternating movements (repeatedly flip hand on palm of opposite hand)
- **lower limb coordination**
  - heel-to-shin test
  - rapid alternating movements (repeatedly tap foot on ground)
- **gait**
  - gait pattern: antalgic, hemiplegic, ataxic, apraxic, Parkinsonian, steppage, broad-based
  - heel-to-toe (tandem) gait
  - pull test for postural instability

Neuroanatomy Review



Medulla

Myotomes

- C5 – Shoulder abduction and elbow flexion
- C6 – Elbow flexion and wrist extension
- C7 – Elbow extension and finger extension
- C8 – Finger flexion
- T1 – Finger abduction
- T2-9 – Intercostal (abdominal reflexes)
- T9-10 – Upper abdominals
- T11-12 – Lower abdominals
- L2 – Hip flexion
- L3 – Hip adduction
- L4 – Knee extension and ankle dorsiflexion
- L5 – Ankle dorsiflexion and big toe extension
- S1 – Plantarflexion

Lumbar Puncture

Definition
- insertion of needle into lumbar cistern for removal of CSF or intrathecal administration of a substance

Indications
- diagnostic: CNS infection (meningitis, encephalitis), SAH (if CT head negative), IIH, NPH, CNS inflammatory disorder (MS, GBS, CNS vasculitis)
- therapeutic: decrease ICP, intrathecal administration of drugs (spinal anesthesia, chemotherapy, antibiotics)
- imaging: intrathecal administration of contrast for myelography or cisternography

Contraindications
- increased ICP in setting of mass, cerebral edema, or obstructive hydrocephalus (risk for cerebral herniation, CT head to rule out)
- skin infection at location for spinal needle insertion or suspected epidural abscess
- bleeding risk: severe thrombocytopenia (<50 x 109/L), high INR (>1.4), coagulopathy

The spinal needle for an LP is inserted into the L3-L4 or L4-L5 intervertebral space, which is below the conus medullaris of the spinal cord (L1-L2)

Complications
- post-LP headache (5-40%)
  - onset within 24-48 h, worse when upright, better when supineprevention: smaller gauge spinal needle (i.e. 22 G) , reinsert stylet prior to needle removal, blunt-ended needle
  - symptomatic treatment: oral analgesics, antiemetics, IV caffeine, sodium benzoate
  - definitive treatment: epidural blood patch
- localized back pain
- infection, bleeding (subdural hematoma, epidural hematoma)
- 6th nerve palsy (unilateral or bilateral, transient)
- epidermoid tumour (prevented by using spinal needle with stylet)
- tonsillar herniation (especiallly in setting of increased ICP)

Do not delay antibiotics while waiting for an LP if bacterial meningitis is suspected

CSF Opening Pressure
- measured using a manometer prior to collection of CSF
- patient positioning during measurement: lateral decubitus position, head neutral, legs extended
- normal CSF opening pressure
  - adults: 6-25 cmH_2O
  - children: 12-28 cmH_2O

RBC count in tube #1>>#4 → traumatic tap
RBC count in tube #1=#4 and elevated, or xanthohromic → SAH

CSF Analysis
- xanthochromia: yellow discolouration of CSF caused by bilirubin from the breakdown of RBCs, diagnostic of SAH
- tube #1: cell count (RBC count, WBC count and differential)
- tube #2: chemistry (protein and glucose)
- tube #3: microbiology (culture and sensitivity, Gram stain), additional tests depending on suspicion
  - viral: PCR for enterovirus, herpes simplex virus, varicella zoster virus, West Nile virus
  - bacterial: polysaccharide antigens of *H. influenzae, N. meningitidis, S. pneumoniae*, TB tests
  - fungal: cryptococcus antigen, fungal culture
- tube #4: cell count for comparison to tube #1

Table 6. CSF Interpretation

	Colour	Protein	Glucose	WBC Count	Other
Normal	Clear	0.15-0.60 g/L	60% of serum glucose (2.2-4.4 mmol/L)	Adults and children: <5 x 10^6/L neonates: <30 x 10^6/L	
Bacterial Meningitis	Cloudy	High (>1.0 g/L)	Normal or low	High (>1000 x 106/L, predominantly neutrophils)	High CSF opening pressure
Viral Meningitis	Clear	Normal or high (0.50-3.0 g/L)	Normal	High (<1000 x 10^6/L, predominantly lymphocytes)	Usually normal CSF opening pressure
Granulomatous Infection (tuberculosis, fungal)	Clear	High (usually <5.0 g/L)	Low	High (<1000 x 10^6/L, predominantly lymphocytes)	High CSF opening pressure in cryptococcal meningitis
Subarachnoid Hemorrhage	Xanthochromia or grossly bloody	High	Normal	High (from blood)	RBC count in tube #1=#4
Traumatic Tap	Grossly bloody	Normal	Slightly high	High (from blood)	RBC count in tube #1>>#4
Idiopathic Intracranial Hypertension	Clear	Normal	Normal	Normal	High CSF opening pressure
Normal Pressure Hydrocephalus	Clear	Normal	Normal	Normal	Normal CSF opening pressure
Multiple Sclerosis	Clear	Normal or slightly high	Normal	Normal or slightly high (predominantly lymphocytes)	Oligoclonal bands on CSF protein electrophoresis
Guillain-Barré Syndrome	Clear	High	Normal	Normal	Albuminocytologic dissociation (high protein, normal WBC count)
Leptomeningeal Disease	Clear	Normal or high	Normal or low	Normal or high lymphocytes	Presence of malignant cells on cytology

Approach to Common Presentations

Weakness

Approach

- **mode of onset**: abrupt (vascular, toxic, metabolic), subacute (neoplastic, infective, inflammatory), insidious (genetic, degenerative, endocrine, neoplastic)
- **course**: worse at onset (vascular), progressive (neoplastic, degenerative, infective, genetic), episodic (vascular, inflammatory), activity dependent (neuromuscular junction, muscular)
- **pattern**: objective vs. subjective, generalized vs. localized, asymmetric vs. symmetric, proximal vs. distal, UMN vs. LMN, peripheral vs. myotomal
- **associated symptoms**: sensory, cortical, autonomic, spinal (i.e. bowel/bladder dysfunction), signs/symptoms specific to various etiologies
- **history**: family history, developmental history, medications, risk factors, recent/preceding exposures
- **investigations for LMN**: NCS/EMG
- **investigations for UMN**: imaging (brain and/or spinal cord)
- **investigations for suspected myopathy**: muscle biopsy, creatine kinase level, NCS/EMG
- **investigations for suspected neuromuscular junction disorder**: NCS/EMG (with repetitive nerve stimulation and single fiber EMG), antibodies (e.g. acetylcholine receptor antibodies and muscle-specific kinase antibodies for MG, voltage-gated calcium channel antibodies for LEMS)

Differential Diagnosis

- objective muscle weakness; also, differentiate between true muscle weakness vs. fatigue
  - generalized
    - myopathy (proximal > distal weakness)
      - endocrine: hypothyroidism, hyperthyroidism, Cushing's syndrome
      - rheumatologic: dermatomyositis, polymyositis, vasculitis
      - infectious: HIV, influenza
      - other: collagen vascular disorders, corticosteroids, statins, EtOH, electrolyte disorders
  - neuromuscular junction (MG, botulism, LEMS, organophosphate poisoning)
  - polyradiculopathy (infection, malignancy, GBS, CIDP)
  - cachexia
  - localized
    - UMN (vasculitis, abscess, brain tumour, vitamin B_{12} deficiency, MS, stroke)
    - radicular pain (i.e. nerve root)
    - anterior horn cell (spinal muscular atrophy, ALS, polio, paraneoplastic)
    - peripheral neuropathy (peroneal muscle atrophy, GBS, leprosy, amyloid, myeloma, DM, lead toxicity)
- no objective muscle weakness
  - chronic illness (cardiac, pulmonary, anemia, infection, malignancy)
  - depression
  - deconditioning

Numbness/Altered Sensation

Approach

- positive sensory symptoms: paresthesia/dysesthesia = tingling, pins and needles, prickling, burning, stabbing
- negative sensory symptoms: hypoesthesia/anesthesia = numbness, reduction/absence of feeling
- determine distribution of sensory loss:
  - nerve root vs. peripheral nerve
  - symmetric stocking-glove pattern (indicative of distal symmetric polyneuropathy)
  - dissociated sensory loss: dorsal column (fine touch, proprioception, vibration) vs. spinothalamic tract (pain and temperature)
- investigations: NCS, blood glucose, vitamin B_{12} level, imaging based on associated findings

Differential Diagnosis

- cerebral: stroke, demyelination, tumour
  - symptoms: hemiplegia, aphasia, apraxia
- brainstem: stroke, demyelination, tumour
  - symptoms: diplopia, vertigo, dysarthria, dysphagia, crossed sensory, and/or motor findings
- spinal cord/radiculopathy: cord infarction, tumour, MS, syringomyelia, vitamin B_{12} deficiency, disc lesion
  - symptoms: back/neck pain, weakness (paraparesis or Brown-Séquard pattern), bowel and bladder dysfunction
- neuropathy: focal compressive neuropathy (based on location and distribution), DM, uremia, vasculitis, vitamin B_{12} deficiency, HIV, Lyme disease, alcohol, paraneoplastic, amyloid
  - polyneuropathy (length-dependent neuropathy) will have a stocking-glove distribution of sensory abnormalities
- other: dermatological (e.g. herpes zoster, angioedema), psychiatric disorders (e.g. panic attacks)

Abnormal Gait

Approach

- characterize abnormal gait (posture, stride length, width between feet, height of step, stability of pelvis, symmetry, arm swing, difficulty turning, tremor, elaborate/inconsistent movements, standing from sitting)
- full neurological exam
- identify red flags (sudden onset, cerebellar ataxia, paresis (hemi-, para-, quadri-) bowel/bladder incontinence)
- workup based on etiology (blood work, neuroimaging, urgent neurologist referral)

Table 7. Types of Gait Disturbance

Location	Description	Disorder
Visual Loss	Broad based gait with tentative steps	Cataract surgery without lens replacement
Proprioceptive Loss	Sensory ataxia: wide-based with high stepping posture and positive Romberg	Demyelinating neuropathies, paraneoplastic syndrome, tabes dorsalis, MS, compressive myelopathy, vitamin B12 deficiency
Peripheral Vestibular Lesion **1. Acute** **2. Bilateral**	1. Vestibular ataxia 2. Disequilibrium	1. Tumour, trauma, infectious, Ménière's disease 2. Ototoxic drugs
Peripheral Nerve Disorder **1. Foot drop** **2. Lumbosacral radiculopathy**	Steppage gait	Acquired/hereditary peripheral neuropathy, compressive peroneal neuropathy, L4-L5 radiculopathy
Myopathies	Waddling gait: broad based, short stepped gait with pronounced lumbar lordosis, rotation of pelvis	Muscular dystrophy, inflammatory myopathy
Pyramidal/Corticospinal Tract Lesion **1. Unilateral** **2. Bilateral**	Spastic gait: spastic foot drop, circumduction, scissoring of legs or toe walking with bilateral circumduction	Unilateral: stroke (ischemic/hemorrhagic) Bilateral: cervical spondylosis, cerebral palsy, spinal cord tumour, combined spinal cord degeneration, MS, motor neuron disease
Basal Ganglia	1. Parkinsonian gait: short stride length, stooped posture, reduced arm swing 2. Choreic/hemiballistic/dystonic gait	Infarct, PD, progressive supranuclear palsy, MSA, Huntington's, Sydenham's chorea, Wilson's disease, SLE, neuroleptic medications, polycythemia vera, genetic dystonia
Cerebellum	Cerebellar ataxic gait, wide-based without high stepping; veers to side of lesion Alcoholic gait	Primary and secondary neoplasm, toxins (EtOH), vitamin E deficiency, hypothyroid, hypoxia, hypoglycemia, paraneoplastic syndrome, vascular lesion

Cranial Nerve Deficits

- see *Cranial Nerve Exam, N3*

CN I: Olfactory Nerve

Signs and Symptoms

- anosmia (complete loss of smell), hyposmia (partial loss of smell)
- can be unilateral or bilateral, congenital or acquired
- change in smell may be described as a change in taste because of importance of both in flavour

Differential Diagnosis

- nasal obstruction: prevention of odorants from reaching olfactory receptors
  - rhinitis (upper respiratory infection, chronic rhinosinusitis, allergic rhinitis, atrophic rhinitis)
  - nasal mass, foreign body, septal deformity, choanal atresia
- involving olfactory receptor neurons (receptors, cell bodies in epithelium, axons that form CN I)
  - head trauma, smoking, COVID-19
- involving central olfactory structures (olfactory bulb, olfactory tract, primary olfactory cortex)
  - neurological disease (AD, PD, MS), anterior cranial fossa mass (meningioma, aneurysm), intracranial surgery, Kallmann syndrome

CN II: Optic Nerve

- see *Optic Neuropathy, N14*

Kallmann syndrome is a congenital disorder of anosmia and hypogonadotropic hypogonadism

CN III: Oculomotor Nerve

Signs and Symptoms
- vertical and horizontal (oblique) binocular diplopia
- eye position is "down and out" (paralysis of superior rectus, inferior rectus, medial rectus, and inferior oblique, unopposed lateral rectus and superior oblique)
- mydriasis (paralysis of pupillary constrictor)
- ptosis (paralysis of levator palpebrae superioris)

Differential Diagnosis
- peripheral (involving CN III)
  - microvascular ischemia (associated with vascular risk factors, GCA)
  - posterior communicating artery aneurysm, uncal herniation, trauma
  - orbital lesion (associated with optic neuropathy, chemosis, proptosis)
  - cavernous sinus lesion (internal carotid artery aneurysm, meningioma, sinus thrombosis, associated with other CN palsies)
  - demyelination (Miller-Fisher variant of GBS)
- fascicular (involving fascicle in midbrain)
  - demyelination (MS)
- nuclear (involving oculomotor nucleus)
  - midbrain infarction/mass
  - often includes bilateral superior rectus paralysis and ptosis with contralateral pyramidal signs ± mydriasis

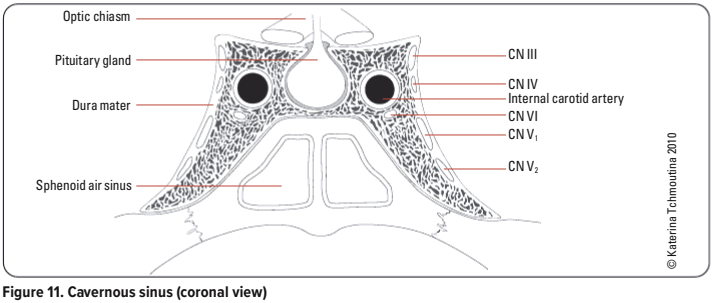

Figure 11. Cavernous sinus (coronal view)

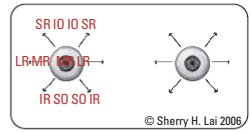

Figure 10. Direction of eye movement to isolate action of extraocular muscle

Parasympathetic axons for pupillary constrictor travel in periphery of CN III
Smaller blood vessels at centre of nerve at greater risk for ischemia
For CN III palsy with reactive pupil, think ischemic cause ("pupil sparing")
For CN III palsy with mydriasis think compressive cause

DDx of CN III Palsy

Ischemic
Compressive (posterior communicating artery aneurysm, uncal herniation, cavernous sinus lesion)
Midbrain lesion (mass, infarction, demyelination)

CN IV: Trochlear Nerve

Signs and Symptoms
- vertical and torsional binocular diplopia
- hypertropia (paralysis of superior oblique, unopposed elevation)
- patient may have contralateral head tilt or describe difficulty going down stairs or reading

Differential Diagnosis
- microvascular ischemia (associated with vascular risk factors, GCA)
- trauma (TBI or surgical)
- cavernous sinus lesion, superior orbital fissure mass (tumour, granuloma)
- demyelination (Miller-Fisher variant of GBS)
- congenital, idiopathic

CN IV is only cranial nerve that exits the brainstem posteriorly
Axons that form CN IV decussate in the midbrain before exiting
Lesions of the trochlear nucleus cause contralateral superior oblique paralysis

CN V: Trigeminal Nerve

- see *Trigeminal Neuralgia, N44*

Signs and Symptoms
- ipsilateral loss of facial sensation and corneal reflex (V1 forms afferent limb)
- ipsilateral weakness of muscles of mastication (V3 only), jaw deviation towards side of weakness

Differential Diagnosis
- pons: infarction, tumour, syringobulbia, demyelination
- peripheral: tumour, aneurysm, chronic meningitis, metastatic infiltration of nerve
- trigeminal ganglion: vestibular schwannoma, meningioma, fracture of middle cranial fossa
- cavernous sinus: internal carotid artery aneurysm, meningioma, sinus thrombosis
- trauma

Jaw deviation is towards the side of a LMN CN V lesion

CN VI: Abducens Nerve

Signs and Symptoms

- horizontal binocular diplopia (worse on lateral gaze towards affected side)
- abduction deficit (paralysis of lateral rectus)
- esotropia (unopposed medial rectus)

Differential Diagnosis

- peripheral (involving CN VI)
  - microvascular ischemia (associated with vascular risk factors, giant cell arteritis)
  - increased or decreased ICP (false localizing sign), trauma, petrous apicitis
  - cavernous sinus lesion (internal carotid artery aneurysm, meningioma, sinus thrombosis, associated with other CN palsies)
  - demyelination (Miller-Fisher variant of GBS)
- fascicular (involving fascicle in pons)
  - demyelination (MS)
- nuclear (involving abducens nucleus)
  - pontine infarction/mass, Duane's syndrome (congenital)
  - presents as lateral gaze palsy due to involvement of internuclear neurons that form pathway to contralateral medial rectus
  - may occur with nuclear facial nerve palsy or corticospinal tract lesion

Distinguishing CN III, IV, and VI Lesions

CN	III	IV	VI
Diplopia	Oblique	Vertical	Horizontal
Eye position	"Down and out"	Hypertropia	Esotropia
Associated Features	Ptosis, mydriasis	Contralateral head tilt	Diplopia worse on lateral gaze

CN VI is vulnerable to increased and decreased ICP, resulting in a false localizing sign

Lesions involving the cavernous sinus can lead to palsies of CN III, IV, VI, V1, and V2 as well as orbital pain and proptosis

CN VII: Facial Nerve

Signs and Symptoms

- unilateral facial weakness (facial droop, flatting of nasolabial fold, inability to wrinkle forehead, and close eyelids)
  - LMN lesion: ipsilateral paralysis
  - UMN lesion: contralateral paralysis with forehead sparing (due to bilateral UMN input to facial motor nucleus for frontalis)
- decreased lacrimation, decreased salivation, hyperacusis (paralysis of stapedius), loss of taste (ageusia) from anterior 2/3 of tongue

Differential Diagnosis

- Bell's palsy (idiopathic): 80-90% of cases (see Otolaryngology, OT22)
- herpes zoster oticus (Ramsay Hunt syndrome)
- otitis media/mastoiditis, sarcoidosis, Lyme meningitis, HIV
- parotid gland disorder, temporal bone fracture

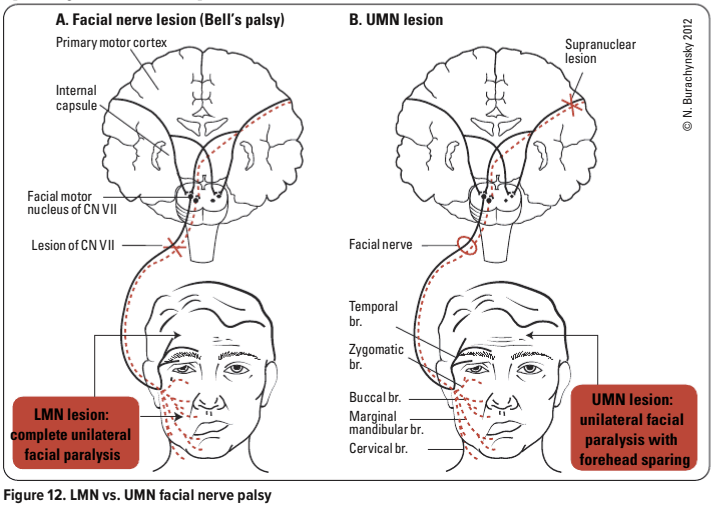

Figure 12. LMN vs. UMN facial nerve palsy

CN VIII: Vestibulocochlear Nerve

- see Otolaryngology, OT9

CN IX: Glossopharyngeal Nerve

Signs and Symptoms
- oropharyngeal dysphagia (paralysis of stylopharyngeus, less severe dysphagia than CN X palsy)
- absent gag reflex (CN IX forms afferent limb)
- loss of taste (ageusia) and sensation from posterior 1/3 of tongue

Glossopharyngeal Neuralgia
- electrical, shock-like, paroxysmal pain from posterior tongue, oropharynx, and ear
- triggers: swallowing, chewing, coughing, talking
- causes: compression (vascular - usually posterior inferior cerebellar artery, neck mass, Eagle syndrome), demyelination, idiopathic
- treated with antiepileptic drugs (carbamazepine), local anesthetic (lidocaine), or surgery (microvascular decompression or surgical ablation of CN IX)

Facial Nerve Branch Memory Aid

"To Zanzibar By Motor Car"
Temporal
Zygomatic
Buccal
Marginal mandibular
Cervical

CN X: Vagus Nerve

Signs and Symptoms
- oropharyngeal dysphagia (paralysis of most muscles of pharynx), for other causes of dysphagia see Gastroenterology, G8
- hoarseness, dysarthria (paralysis of intrinsic muscles of larynx)
- contralateral uvula deviation (paralysis of most muscles of soft palate)
- absent gag reflex (CN X forms efferent limb)

CN X LMN lesions cause contralateral uvula deviation because of paralysis of ipsilateral muscles of soft palate that prevents ipsilateral palatal elevation

When screening for dysphagia and assessing aspiration risk, the presence of a gag reflex is insufficient; the correct screening test is to observe the patient drinking water from a cup while observing for any coughing, choking, or "wetness" of voice

CN XI: Accessory Nerve

Signs and Symptoms
- contralateral head turn weakness (paralysis of sternocleidomastoid)
- ipsilateral shoulder shrug weakness (paralysis of trapezius)
- LMN lesion: ipsilateral paralysis, UMN lesion: contralateral paralysis

CN XI is vulnerable to injury during neck surgery

CN XII: Hypoglossal Nerve

Signs and Symptoms
- tongue weakness (paralysis of ipsilateral muscles of tongue, except palatoglossus)
- tongue deviation to weak side on protrusion (ipsilateral to LMN lesion, contralateral to UMN lesion)
- signs of LMN lesion: atrophy, fasciculations

Neuro-Ophthalmology

Optic Neuropathy

Signs and Symptoms
- vision loss (decreased visual acuity, decreased colour vision, visual field defect)
- RAPD (only if unilateral or asymmetric bilateral optic neuropathy)
- change in appearance of optic disc (optic disc edema, optic disc pallor)

Optic Neuritis
- see *Multiple Sclerosis, N55*

Ischemic Optic Neuropathy
- anterior ischemic optic neuropathy (AION)
  - ischemia of optic nerve head
  - arteritic: most commonly due to GCA
  - non-arteritic: associated with vascular risk factors (DM, hyperlipidemia, HTN)
- posterior ischemic optic neuropathy (PION)
  - ischemia of retrobulbar segment of optic nerve
  - usually perioperative

Other Causes
- traumatic, compressive, toxic, nutritional, hereditary

Optic Atrophy

- non-reversible death of retinal ganglion cells that form the optic nerve
- optic disc pallor on fundoscopic exam, permanent vision loss (decreased visual acuity, visual field defect, decreased colour vision)
- occurs in setting of severe optic neuropathy

Optic Disc Edema

Table 8. Common Causes of Optic Disc Edema

	Optic Neuritis	Papilledema	Anterior Ischemic Optic Neuropathy (AION)	Central Retinal Vein Occlusion (CRVO)
Age	<50 yr	Any	>50 yr but usually >70 yr	>50 yr
Vision	Acute to subacute monocular/ binocular central vision loss (decreased visual acuity and colour vision) with recovery	Late vision loss	Acute, painless unilateral vision loss over h to d with decreased colour vision	Painless unilateral variable vision loss
Symptoms	Pain with eye movement	Symptoms of increased intracranial pressure (headache, nausea, vomiting, focal neurological deficits)	GCA: headache, scalp tenderness, jaw claudication, systemic (weight loss, fatigue, fever)	Acute, painless monocular vision loss
Pupil	RAPD	No RAPD	RAPD	± RAPD
Fundus	Optic disc edema involves optic nerve head, optic disc pallor in chronic stage if severe	Bilateral optic disc edema, retinal hemorrhage, no venous pulsations	Segmental optic disc edema, retinal dot and flame hemorrhages	Optic disc edema, venous engorgement, retinal hemorrhage
Etiologies	MS, neuromyelitis optica, other inflammatory and infectious diseases	Increased ICP see *Table 24, Headaches, N47* IIH if CT/CT venography rules out space-occupying lesion and cerebral venous thrombosis	Arteritic: GCA Non-arteritic: atherosclerosis, DM, hyperlipidemia, HTN	Associated with vascular risk factors, DM, glaucoma, SLE
Investigations	MRI brain and orbits with gadolinium	Emergent CT with CT venography, LP if CT normal, to measure CSF opening pressure	CBC, ESR, C-reactive protein temporal artery biopsy, MRI orbits with gadolinium	Fluorescein angiography, thrombophilia workup if no cause identified (younger patients)
Treatment	High-dose IV or PO corticosteroids (accelerates recovery of vision, does not improve long-term outcome)	Treat underlying cause of increased ICP	Arteritic: corticosteroids Non-arteritic: no proven treatment	Optimize risk factors, reduce intraocular pressure, ± laser, ± vascular endothelial growth factor) inhibitors

If diagnosis of GCA is suspected, do not wait for temporal artery biopsy; begin treatment with corticosteroids immediately

Visual Field Defects

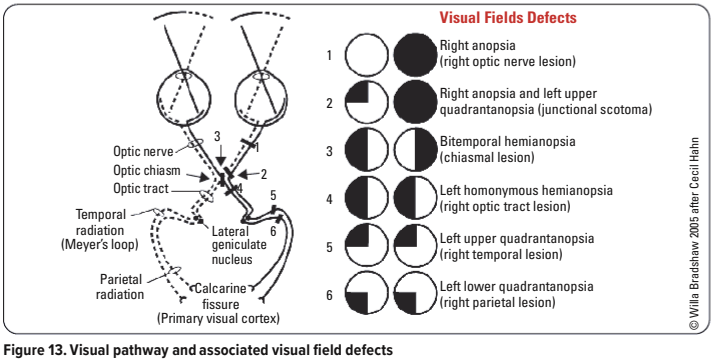

Figure 13. Visual pathway and associated visual field defects

DDx of Bitemporal Hemianopsia by Age
Children: craniopharyngioma
20-50 yr: pituitary adenoma
>60 yr: meningioma

In homonymous hemianopsia, more congruent deficits are caused by more posterior lesions; macular sparing may occur with occipital lesions

Lesion of the frontal eye field (FEF) (i.e. stroke, tumour) causes eye deviation towards the side of the lesion

Overactivation of the FEF (i.e. seizure) causes eye deviation away from the side of overactivation

Lesion of the paramedian pontine reticular formation (PPRF) (i.e. stroke, tumour) causes eye deviation away from the side of the lesion

Amaurosis Fugax

- see Ophthalmology, OP36 and *Stroke, N51*

Pupil Abnormalities

- see Ophthalmology, OP29

Eye Movement Disorders

Internuclear Ophthalmoplegia

Pathophysiology
- caused by lesion of medial longitudinal fasciculus (MLF) that impairs horizontal gaze pathway
- MLF connects abducens nucleus in pons to contralateral medial rectus subnucleus of oculomotor nucleus in midbrain

Signs and Symptoms
- horizontal binocular diplopia (worse on lateral gaze towards opposite side of lesion)
- adduction deficit in eye ipsilateral to lesion
- horizontal abducting nystagmus in eye contralateral to lesion
- can differentiate from medial rectus denervation (i.e. CN III palsy) by testing convergence since it is separate from horizontal gaze pathway
- can be bilateral (especially MS)

Etiology
- demyelination of MLF (i.e. MS), brainstem infarction/mass

Investigation
- MRI brain

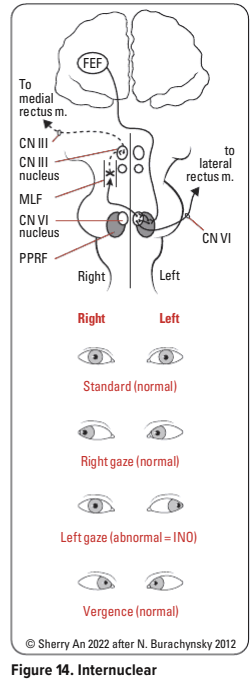

Figure 14. Internuclear ophthalmoplegia

Diplopia

Definition
- visual symptom characterized by the perception of two images of a single object
- also called double vision

Classification
- monocular: diplopia remains when unaffected eye is closed
- binocular: diplopia disappears when either eye is closed
- based on where the two images are relative to each other, diplopia can be described as vertical, horizontal or oblique

Etiology – Monocular
- benign optical problem (refractive error, cataract, corneal abnormality, dry eye) or functional

Etiology – Binocular
- caused by ocular misalignment
- classification of cause
  - muscle: extraocular muscle restriction/entrapment (orbital fracture, orbital mass, Graves' ophthalmopathy), myopathy
  - neuromuscular junction: MG, LEMS
  - nerve: CN III, IV, VI palsy
  - brain: internuclear ophthalmoplegia, stroke, Wernicke's encephalopathy

Approach
- monocular or binocular
- vertical, horizontal or oblique
- worse in specific direction of gaze
- onset (acute, chronic), progression
- corrective head positions
- associated symptoms (ptosis, miosis/mydriasis, symptoms of GCA, fatigable weakness)

Diplopia worse at the end of the day suggests MG (i.e. variable and fatigable), usually with associated ptosis

Nystgmus

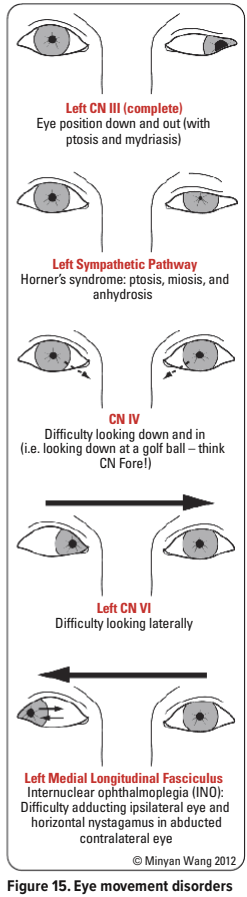
Definition
- rapid, involuntary, small-amplitude eye movements that are rhythmic in nature

Classification
- based on axis of movement (vertical, horizontal, torsional)
- based on movement type
  - jerk: slow drift in one direction (slow phase) followed by a fast corrective movement in the opposite direction (fast phase), direction of nystagmus is named after fast phase, fast phase may occur in one direction or multiple directions (unidirectional, bidirectional, multidirectional)
  - pendular: smooth, sinusoidal pattern without a fast phase

- based on cause
  - congenital or acquired, physiological or pathological (peripheral or central)

Table 9. Nystagmus Features

Characteristic	Peripheral (Vestibular)	Central (Brainstem)
Lesion Location	Peripheral vestibular system (semicircular canals, vestibulocochlear nerve)	CNS (usually cerebellum, brainstem or visual pathway)
Nystagmus Features	Often horizontal and torsional components, unidirectional, fast phase away from lesion	Often purely vertical, horizontal or torsional, can be bidirectional or multidirectional
Gaze Fixation	Decreases nystagmus	No effect on nystagmus
Vertigo	Severe	Mild
Auditory Symptoms	Common	Rare
Other Neurological Signs	Rare	Common
Adaptation	Within days	Often persists
Causes	Benign paroxysmal positional vertigo (BPPV), vestibular neuritis, Ménière's disease, trauma ototoxic medications	MS, stroke, neoplastic, paraneoplastic, medications



Left CN III (complete)
Eye position down and out (with ptosis and mydriasis)
Left Sympathetic Pathway
Horner's syndrome: ptosis, miosis, and anhydrosis
CN IV
Difficulty looking down and in (i.e. looking down at a golf ball – think CN Fore!)
Left CN VI
Difficulty looking laterally
Left Medial Longitudinal Fasciculus
Internuclear ophthalmoplegia (INO): Difficulty adducting ipsilateral eye and horizontal nystagamus in abducted contralateral eye
© Minyan Wang 2012

Figure 15. Eye movement disorders and Horner's syndrome

Nutritional Deficiencies and Toxic Injuries

- sufficient nutritional intake is required for optimal functioning of the nervous system; deficiencies in the following nutrients may result in CNS and PNS abnormalities (potential neurological symptoms are provided)

Table 10. Nutritional Deficiency Features and Management

Vitamin Deficiency	Neurological Clinical Manifestation	Investigation	Treatment*
Vitamin B_{12}	Paresthesias and sensory ataxia are the most common initial symptoms Myelopathy (subacute combined degeneration), peripheral neuropathy Neuropsychiatric symptoms: memory impairment, change in personality and mood, delirium, and psychosis Optic neuropathy	CBC and blood smear Serum cobalamin Serum methylmalonic acid Serum homocysteine Intrinsic factor antibodies	Vitamin B_{12} 1000 µg IM once weekly for 4 wk then 1000 µg PO daily or IM monthly thereafter
Folate	May be clinically indistinguishable from vitamin B_{12} deficiency Myelopathy, peripheral neuropathy Neuropsychiatric symptoms Neural tube defects (in fetus	Serum folate Homocysteine	Folic acid 1-5 mg PO TID initially, then 1 mg PO once daily thereafter
Copper	Myelopathy, myeloneuropathy, sensory ataxia, spastic gait (similar to vitamin B_{12} deficiency) Severe sensory loss	Serum copper and ceruloplasmin Urinary copper MRI spine; EMG/NCS	Discontinue zinc; copper 8 mg/d PO daily for 1 wk, then 4 mg PO daily for 2 wk, then 2 mg PO daily thereafter
Vitamin E	Ophthalmoplegia, retinopathy, spinocerebellar syndrome with peripheral neuropathy (with signs of cerebellar ataxia), psychomotor impairment	Serum vitamin E Ratio serum vitamin E to sum of cholesterol and triglycerides; EMG/NCS	Vitamin E 2200 mg/kg/d PO or IM
Thiamine (Vitamin B_1)	Three manifestations include: beriberi (dry and wet), infantile beriberi, Wernicke-Korsakoff syndrome, see *Cerebellar Disorders, N36*	Clinical diagnosis MRI brain	Thiamine 200 mg IV TID, followed by 10 mg PO once daily until nutritional status stable If suspected Wernicke-Korsakoff syndrome: 500 mg TID for 2 d, followed by 250 mg IV or IM for 2 d
Pyridoxine (Vitamin B_6)	Painful sensorimotor peripheral neuropathy, intractable epilepsy in infants, confusion	Serum pyridoxal phosphate EMG/NCS EEG in infants and children	Pyridoxine 50-100 mg PO once daily
Niacin (Vitamin B_3)	Pellagra: encephalopathy, dementia, and peripheral neuropathy	Urinary nicotinamide mononucleotide (NMN) and nuclear matrix protein (NMP) tests Niacin index	Nicotinic acid 25-50 mg PO daily or IM once daily. When supplementing, be aware of "niacin flush" in some patients

- also consider occupational neurotoxic syndromes secondary to exposure to pesticides, solvents, and metals. Encephalopathy, extrapyramidal features, neurodegenerative diseases, and peripheral neuropathy are commonly encountered. Onset and progression of neurological diseases should be temporally related to neurotoxin exposure. Main toxins associated with neurotoxicity are listed on *Table 11, N18*

Table 11. Selected Occupational Neurotoxic Syndromes

Toxin	Associated Occupations	Characteristic Neurological Findings
Organic Solvents	Printer, spray painters, industrial cleaners, paint or glue manufacturers, graphic industry, electronic industry, plastic industry	Acutely, may present as nausea, headache, concentration difficulty Long-term exposure may lead to "chronic solvent-induced encephalopathy" (characterized by mild-to-severe cognitive impairment), seizures, death
Pesticides (e.g. insecticides, fungicides, rodenticides, fumigants, herbicides)	Agricultural work, pesticide manufacturing and formulating, highway and railway workers, green house, forestry, and nursery workers	May increase the risk of PD
Heavy Metals (e.g. lead, mercury, manganese, aluminum, arsenic, tin, thallium)	Battery and metal production (e.g. solder, pipes), chemical and electronic application industries, steel manufacturing, welders, alloy workers, transportation, packaging, construction	**Lead:** headache, difficulty concentrating, deficits in short-term memory, delayed/reversed development, permanent learning disabilities, peripheral neuropathy (commonly presenting with radial neuropathy resulting in wrist drop), seizures, coma, delirium, death from encephalopathy (rare) **Mercury:** psychiatric symptoms, ataxia, tremor, visual loss, hearing loss, tiredness, memory disturbances, peripheral neuropathy **Manganese:** psychiatric symptoms, hallucinations ("manganese madness"), extrapyramidal features, headache, dystonia, parkinsonism (manganism) **Aluminum:** implicated in AD and Down's syndrome pathogenesis **Arsenic:** peripheral neuropathy, encephalopathy, sleeplessness/sleepiness, irritability, headache, spasms and fatigue in appendicular muscles, peripheral neuropathy **Thallium:** ataxia, seizures, motor neuropathy, brain edema **Tin:** mental status changes with persistent neuropsychological abnormalities
Gases (e.g. carbon dioxide, nitrous oxide, formaldehyde)	Anesthesia, disinfection, manufacture of illuminating gas and water-gas	Cognitive/behavioural and emotional symptoms, parkinsonian syndromes Nitrous oxide misuse may result in a functional vitamin B12 deficiency and thus symptoms of subacute combined degeneration

Neurologic Complications due to Toxic Injuries Related to Bariatric Surgery

- deficiencies of both fat- and water-soluble vitamins may occur following malabsorptive bariatric surgery
- patients who have undergone malabsorptive surgery should be monitored for late metabolic complications (e.g. B_{12} and copper deficiency) and neurological manifestations (e.g. peripheral neuropathy)

Seizure Disorders and Epilepsy

Seizure

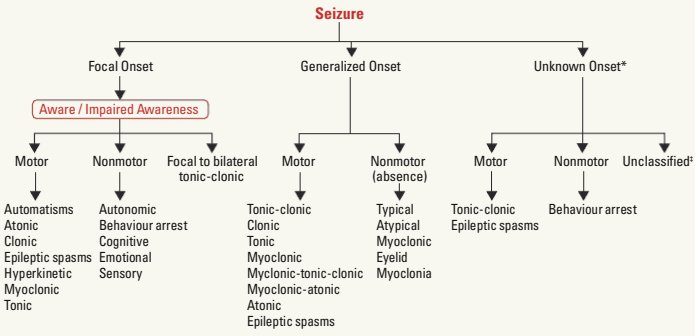
Definitions

- seizure: transient signs and/or symptoms due to abnormal hyper-synchronization of neurons
  - precipitating factors (acute brain insult) such as: EtOH and illicit drug use/withdrawal; brain injury/abnormality (tumour, trauma, vascular); CNS infection; fever (children); metabolic (hypoglycemia, electrolyte abnormalities, liver/renal failure); medications; or genetic cause
- epilepsy: enduring predisposition to generate epileptic seizures, with its associated neurobiologic, cognitive, psychological, and social consequences
  - diagnosis of epilepsy requires:
    1. at least two unprovoked seizures >24 h apart
    2. one unprovoked seizure and a probability of further seizures similar to the general recurrence risk (≥60%) of two unprovoked seizures, occurring over the next 10 yr
    3. diagnosis of an epilepsy syndrome
  - etiologies: genetic; structural (e.g. prior stroke, tumour, meningo/encephalitis, perinatal insult, vascular malformation, malformation of cortical development, neurodegenerative); or unknown

Stroke is the most common cause of late-onset (>50 yr) seizures, accounting for 50-80% of cases

Seizures and Dementia
Neurodegenerative diseases can underlie seizures. Conversely, seizures can be a cause of dementia

Classification



*Unknown Onset may be reclassified into focal or generalized onset with further information or future observed seizures
‡ Unclassified comprises both seizures with patterns that do not fit other categories or lack information

Figure 16. International League Against Epilepsy (ILAE) 2017 seizure classification

Clinical Features

- **focal (partial) seizures**
  - focal can secondarily generalize or remain focal
  - focal without impaired awareness (i.e. "simple partial seizures") → focal with impaired awareness (i.e. "complex partial seizures") → secondarily generalized seizures
  - **focal aware (formerly simple partial)**
    - motor: dystonic posturing, clonic movements, forceful turning of eyes and/or head, focal muscle rigidity/jerking ± Jacksonian march (spreading to adjacent muscle groups)
    - sensory: unusual sensations affecting vision, hearing, smell, taste or touch
    - autonomic: epigastric discomfort, pallor, sweating, flushing, piloerection, pupillary dilatation
  - **focal impaired awareness (formerly complex partial)**
    - classic complex seizure is characterized by automatisms such as chewing, swallowing, lip-smacking, scratching, fumbling, running, disrobing, and other stereotypic movements
    - other forms: dysphasic, dysmnesic (déjà vu), cognitive (disorientation of time sense), affective (fear, anger), illusions, structured hallucinations (music, scenes, taste, smells), epigastric fullness
- **generalized seizures**
  - **absence (petit mal):** usually seen in children, unresponsive for 5-10 s with arrest of activity, staring, blinking or eye-rolling, no post-ictal confusion; 3 Hz spike and slow wave activity on EEG
  - **clonic**: whole body repetitive rhythmic jerking movements
  - **tonic**: whole body muscle rigidity in flexion or extension
  - **tonic-clonic (grand mal)**
    - may have prodrome of unease or irritability hours to days before
    - tonic ictal phase: muscle rigidity
    - clonic ictal phase: repetitive violent jerking of face and limbs, tongue biting, cyanosis, frothing, incontinence
    - post-ictal phase: flaccid limbs, extensor plantar reflexes, headache, confusion, aching muscles, sore tongue, amnesia, elevated creatine kinase lasting hours, may have focal paralysis ('Todd's paralysis)
  - **myoclonic**: sporadic contractions localized to muscle groups of one or more limbs
  - **atonic**: loss of muscle tone leading to drop attack

Temporal lobe seizures are suggested by an aura of fear, olfactory or gustatory hallucinations, and visceral or déjà vu sensations
Frontoparietal cortex seizures are suggested by contralateral focal sensory or motor phenomena

Antiepileptic Drug Monotherapy for Epilepsy: A Network Meta-Analysis of Individual Participant Data
Cochrane DB Syst Rev 2017;CD011412
Purpose: To compare the time to withdrawal of treatment, time to remission, and time to first seizure of 10 antiepileptic drug treatments for adults and children with partial onset seizures
Methods: Articles were identified from Cochrane Epilepsy's Specialised Register, CENTRAL, MEDLINE, SCOPUS, and two clinical trial registers. Individual patient data was identified for network-meta analysis
Results: Carbamazepine and lamotrigine are suitable first-line treatments for partial onset seizures with levetiracetam as a suitable alternative. Evidence supports sodium valproate as first-line treatment for generalized tonic-clonic seizures with lamotrigine and levetiracetam as suitable alternatives, particularly for females of child-bearing age

DDx of Convulsions
Syncope, psychogenic non-epileptic seizures, hyperventilation, panic disorder, TIA, hypoglycemia, movement disorder, alcoholic blackouts, migraines (confusional, vertebrobasilar), narcolepsy (cataplexy)

Table 12. Classic Factors Differentiating Seizure, Syncope and Pseudoseizure

Characteristic	Seizure	Syncope	Dissociative/Functional Seizures
Timing	Day or night (especially from sleep)	Day	Day, other people present
Onset	Sudden, in any position	Gradual, upright position (not recumbent)	Provoked by emotional disturbance or suggestion
Early Symptoms or Signs	Possible specific aura	Lightheadedness, pallor, diaphoresis, tunnel vision	Variable
Duration	Brief or prolonged	Brief	Often prolonged
Incontinence	Common	Possible but rare	Rare
Post-Ictal	Confusion, aphasia, Todd's paresis, fatigue	No	Variable, often none
Motor Activity	Synchronous, stereotypic, automatisms (common in complex partial), lateral tongue biting, eyes open or eyes rolled back	Occasional brief tonic stiffening, can have "convulsive syncope"	Prolonged episodes, opisthotonos, eye closure, irregular limb movements, shaking head, pelvic thrust, crying, tongue biting at the tip
Injury	Common	Rare unless from fall	Rare
EEG	Usually abnormal ± interictal discharges	Normal	Normal

*Pseudoseizures do not rule out seizures (not uncommon to have both)

Note that seizures originating in the frontal lobes may look like psychogenic non-epileptic spells due to an abundance of repetitive hyperkinetic movements; they often occur during sleep

By law, the Ministry of Transportation in most provinces must be contacted for all patients who have had a seizure, patients will have their license suspended until seizure free for 6 mo, commercial drivers face a longer wait

EEG findings suggestive of predisposition to epilepsy: spike and wave discharges, polyspike and wave discharges, spike-wave complex discharges

EEG has a 17% sensitivity and 95% specificity after first unprovoked seizure, sensitivity increases to 51% if EEG is performed within 24 h
If the first routine EEG is normal, a sleep-deprived sleep EEG should be considered to increase the likelihood of detecting an abnormality

- alcoholic withdrawal seizures may occur up to 2 d from the last exposure to EtOH (see Emergency Medicine, ER54)

Investigations
- CBC, electrolytes, Ca^{2+}, Mg^{2+}, PO_4^{3-}, fasting blood glucose, Cr, liver enzymes, creatine kinase, prolactin
- toxicology screen, EtOH level, ASM level (if applicable)
- CT/MRI (if new seizure without identified cause or known seizure history with new neurologic signs/symptoms)
  (Note: Neuroimaging may be normal in up to 90% of cases following the first unprovoked seizure)
- LP (if fever or meningismus)
- EEG (Note: EEG is specific but not sensitive)

Treatment
- avoid precipitating factors
- prognosis: risk of seizure recurrence increases with the number of unprovoked seizures at initial presentation, abnormal EEG, and presence of a neurological disorder
- indications for ASM: EEG with epileptiform activity, prior brain injury (organic brain disease, prior head injury, or CNS infection), abnormal neurologic examination or neuroimaging findings, nocturnal seizure, recurrent unprovoked seizure
- psychosocial issues: stigma of seizures, education of patient and family, status of driver's license, pregnancy issues
- safety issues: driving, operating heavy machinery, bathing, swimming alone
- appropriate follow-up; refer for evaluation for possible surgical treatment if focal and refractory

Status Epilepticus

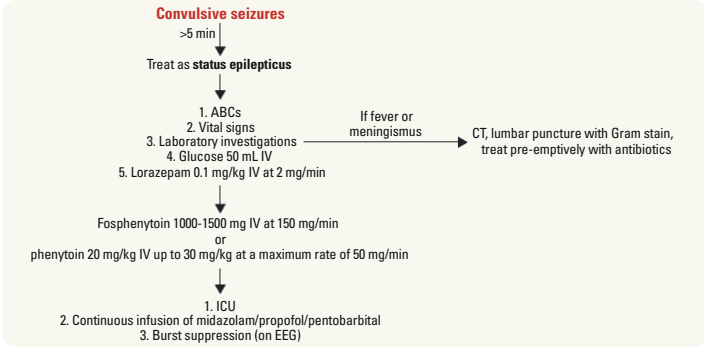
- **definition**: unremitting seizure or successive seizures without return to baseline state of >5 min
- **complications**: anoxia, cerebral ischemia and cerebral edema, MI, arrhythmias, cardiac arrest, rhabdomyolysis and renal failure, aspiration pneumonia/pneumonitis, death (20%)
- **initial measures**: ABCs, vitals, monitors, capillary glucose (STAT), ECG, nasal O_2, IV normal saline, IV glucose, IV thiamine, arterial blood gas (if respiratory distress/cyanotic)
- **blood work**: electrolytes, Ca^{2+}, Mg^{2+}, PO_4^{3-}, glucose, CBC, toxicology screen, EtOH level, ASM levels
- focused history: onset, past history of seizures, drug and EtOH ingestion, past medical history, associated symptoms, witnesses/collateral history
- **physical exam (once seizures controlled):** LOC, vitals, HEENT (nuchal rigidity, head trauma, tongue biting, papilledema), complete neurological exam, signs of neurocutaneous disorders, decreased breath sounds, cardiac murmurs or arrhythmias, urinary incontinence, MSK exam (rule out injuries)
- **post-treatment stabilization**: CT head, EEG, Foley catheter to monitor urine output, urine toxicology screen, monitor for rhabdomyolysis, and IV fluids to maintain normal cerebral perfusion pressure

Medical Emergency: Status epilepticus can cause irreversible brain damage without treatment

The most common causes of status epilepticus in adults are failure to take ASM, remote symptomatic causes, and stroke
Despite being a common cause of seizures, EtOH withdrawal is a rare cause of status epilepticus

Consider non-convulsive status epilepticus in a patient who has a persistent decreased level of awareness >20 min after a generalized seizure; order an EEG if unsure

Antiseizure Medications
- focal and most generalized seizures
  - valproate (Depakene®), lamotrigine (Lamictal®), levetiracetam (Keppra®), topiramate (Topamax®), phenobarbital (Phenobarb®), primidone, zonisamide, rufinamide (Banzel®), felbamate, benzodiazepines
- primarily focal seizures (± 2° generalization)
  - carbamazepine (Tegretol®), phenytoin (Dilantin®), gabapentin (Neurontin®), lacosamide (Vimpat®), oxcarbazepine (Trileptal®), eslicarbazepine acetate (Aptiom®), pregabalin (Lyrica®), tiagabine (Gabitril®), vigabatrin (Sabril®)
- absence seizure: ethosuximide (Zarontin®)



Convulsive seizures
>5 min
Treat as status epilepticus
1. ABCs
2. Vital signs
3. Laboratory investigations
4. Glucose 50 mL IV
5. Lorazepam 0.1 mg/kg IV at 2 mg/min
If fever or meningismus
CT, lumbar puncture with Gram stain, treat pre-emptively with antibiotics
Fosphenytoin 1000-1500 mg IV at 150 mg/min
or
phenytoin 20 mg/kg IV up to 30 mg/kg at a maximum rate of 50 mg/min
1. ICU
2. Continuous infusion of midazolam/propofol/pentobarbital
3. Burst suppression (on EEG)

Figure 17. Status epilepticus treatment algorithm

Complex partial status epilepticus can resemble schizophrenia or psychotic depression

Teratogenicity of anticonvulsants includes neural tube defects, cleft palate, urogenital malformations, and heart defects. Advise patient planning pregnancy to take 1-4 mg/d of folic acid. Optimize AEDs with lowest possible dose associated with good seizure control, preferably monotherapy if possible. The risk of fetal malformations with AEDs is 2x the general population; highest risk associated with valproic acid and/or 2+ concurrent AEDs. Consider pre-conception AED levels if patient is well-controlled, monthly serum levels during pregnancy, and titrate AED to maintain pre-conception serum levels. Refer to high-risk OB for intrapartum fetal screening

Behavioural Neurology

- see Psychiatry, PS23

Acute Confusional State/Delirium

Table 13. Selected Causes of Acute Confusion

	Etiology	Key Clinical Features	Investigations
Vascular	SAH	Thunderclap H/A, increased ICP, meningismus, loss of consciousness	CT, LP Angiography if CT and LP negative
	Stroke/TIA (ischemic or hemorrhagic)	Focal neurological signs	CT, MRI
Infectious	Meningitis	Fever, H/A, nausea, photophobia, meningismus	CT, LP
	Encephalitis	Fever, H/A, ± seizure Focal neurological signs	CT, LP MRI
	Abscess	Increased ICP Focal neurological signs	CT with contrast (often ring enhancing lesion)
Traumatic	Diffuse axonal shear, epidural hematoma, subdural hematoma	Trauma Hx Increased ICP Focal neurological signs	CT MRI
Autoimmune	Acute CNS vasculitis	Skin rash, active joints	ANA, ANCA, RF MRI Angiography
	Paraneoplastic or autoimmune encephalitis (anti-NMDA-R)	Onset: psychiatric features, memory loss, seizures Delayed: movement disorder, and changes in BP, HR, and temperature	Serum and CSF (test for presence of antibodies), search for primary neoplasm
Neoplastic	Primary or secondary CNS neoplasm	Increased ICP Focal neurological signs Papilledema	CT MRI Search for primary neoplasm if metastatic disease
Seizure	Focal seizure with impaired awareness, non-convulsive status epilepticus, post-ictal confusion	See *Seizure Disorders and Epilepsy, N18*	EEG CT or MRI Workup for seizure triggers
Primary Psychiatric	Psychotic, mood, and anxiety disorder	No organic signs or symptoms	No specific tests
Other	Illicit drug use (e.g. cocaine)	Chest pain, cough with black sputum, new-onset seizure, HTN, increased ICP, dyspnea	Vital signs Serum chemistry and electrolyte analysis Serum and urine toxicology screen
	Medications (e.g. anticholinergic side effects, benzodiazepines)	Flushing, dry skin and mucous membranes, mydriasis with loss of accommodation	Serum chemistry and electrolyte analysis
	Neuroleptic Malignant Syndrome	Antipsychotic medication use Muscle rigidity Hyperthermia Autonomic instability	Serum chemistry and electrolyte analysis

Delirium is a medical emergency carrying significant risk of morbidity and mortality. It is diagnosed using the Confusion Assessment Method when feature 1 AND 2 as well as feature 3 OR 4 are present:

- **Feature 1:** acute onset and fluctuating course
- **Feature 2:** inattention
- **Feature 3:** disorganized thinking
- **Feature 4:** altered LOC

Mild Neurocognitive Disorder (Mild Cognitive Impairment)

Definition
- change in cognition
  - Impairment in one or more cognitive domains (amnestic vs. non-amnestic)
  - preservation of independence or minimal impairment in ADLs and IADLs
  - Not meeting criteria for major NCD

Epidemiology
- mild NCD: 2-10% at age 65 and 5-25% by age 85

Risk Factors
- non-modifiable: age, history of stroke or heart disease, and apolipoprotein E (APOE) ε4 genotype
- modifiable: educational level and vascular risk factors (e.g. HTN, DM, obesity)

Clinical Features
- cognitive impairment with different subtypes
  - single domain vs. multiple domains (e.g. memory, visual spatial function, attention, executive function, language)
  - amnestic (memory impairment) vs. non-amnestic (memory function preserved)
  - amnestic subtype is the most common and most associated with AD pathology
  - important to ascertain that memory complaints represent change from baseline
- neuropsychiatric symptoms: depression (50%), irritability, anxiety, aggression, and apathy

Investigations
- establish a baseline for follow-up with validated cognitive screening tool
- clinical interview with patient and caregivers, including family history
- neuropsychological testing
  - MMSE (not sensitive to early cognitive change) or MoCA (more sensitive); should be done in conjunction with a history and neurological exam or with other neurocognitive tests
  - if abnormal, follow-up in one year to monitor cognitive and functional decline
- neuroimaging
  - role uncertain; non-contrast CT head often ordered to evaluate for structural abnormalities (CVD, subdural hematoma, NPH, or mass lesion); MRI is helpful to establish baseline and to look for other possible reversible causes of cognitive impairment
- other testing to exclude treatable conditions (e.g. vitamin B12 deficiency, hypothyroidism, seizures, autoimmune encephalitis) and underlying psychiatric conditions (e.g. depression)

Treatment
- non-pharmacologic management: exercise training for 6 mo is likely to improve cognition; insufficient evidence to support or refute cognitive intervention, it may improve outcome on select cognitive measures
- pharmacologic management: monitoring and management of HTN and other vascular risk factors is recommended
- no evidence for cholinesterase inhibitors, anti-inflammatory agents

Prognosis
- development of major NCD for age ≥65 is 14.9% after 2 yr
- relative risk of major NCD is 3.3 after 2-5 yr

Prevalence of Depression in Patients with Mild Cognitive Impairment: A Systematic Review and Meta-Analysis
JAMA Psychiatry 2017;74:58-67
Purpose: To estimate the prevalence of depression in individuals with mild cognitive impairment.
Methods: Review of articles with patients with mild cognitive impairment as a primary study group, reported depression/depressive symptoms using a validated tool, and reported the prevalence of depression in patients with mild cognitive impairment.
Results: Pooled prevalence of depression patients with mild cognitive impairment was 32% (95% CI 27-37%). Prevalence in community-based populations (25%, 95% CI 19-30) was significantly lower than clinic-based populations (40%, 95% CI 32-48).
Conclusions: Prevalence of depression in patients with mild cognitive impairment is high.

Major Neurocognitive Disorder (formerly Dementia)

- see Psychiatry, PS24

Definition
- progressive decline in cognitive function with impairment in ADLs/IADLs (e.g. shopping, food preparation, finances, medication management)
- diagnosis of major NCD requires presence of significant cognitive decline from a previous level of performance in one or more cognitive domains based on:
  a) concern of the individual or a knowledgeable informant AND
  b) substantial impairment in cognitive performance either documented by standardized neuropsychological testing or quantified clinical assessment

Epidemiology
- major NCD: 1-2% at age 65 and reaching as high as 30% by age 85
- major NCD due to AD is uncommon before age 60
- major NCD due to frontotemporal lobar degeneration has an earlier onset and represents a progressively smaller fraction of all NCDs with increasing age

Etiology *(see Table 14, N23)*
- reversible causes: EtOH (intoxication or withdrawal, Wernicke's encephalopathy), medication (benzodiazepines, anticholinergics), heavy metal toxicity, hepatic or renal failure, vitamin B12 deficiency, glucose, cortisol, thyroid dysfunction, NPH, depression (pseudodementia), intracranial tumour, subdural hematoma, and hypercalcemia
- must rule out delirium

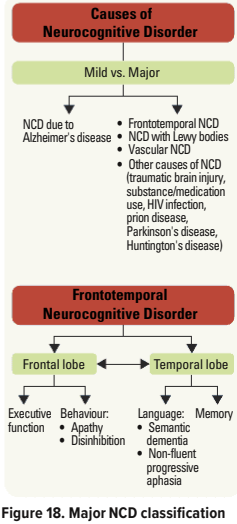


Figure 18. Major NCD classification

History
- "geriatric giants"
  - confusion/incontinence/falls
  - memory and safety (wandering, leaving doors unlocked, leaving stove on, losing objects, driving)
  - behavioural (mood, anxiety, psychosis, suicidal ideation, personality changes, aggression)
  - polypharmacy and compliance (sedative hypnotics, antipsychotics, antidepressants, anticholinergics)
- ADLs and IADLs
- cardiovascular, endocrine, neoplastic, renal ROS, head trauma history
- EtOH, smoking
- collateral history
- FHx

Physical Exam
- BP
- hearing and vision
- neurological exam with attention to signs of parkinsonism, UMN findings
- general physical exam with focus on CVD, patient-specific risk factors, and history
- MMSE or MoCA, clock drawing, frontal lobe testing (go/no-go, word lists, similarities, proverb)

Investigations
- rule out reversible causes
  - CBC (note MCV for evidence of alcohol use and vitamin B_{12} deficiency), glucose, TSH, vitamin B_{12}, RBC folate
  - electrolytes, LFTs, renal function, lipids, serum calcium
  - CT head, MRI as indicated, SPECT (optional)
  - as clinically indicated: VDRL, HIV, ANA, anti-dsDNA, ANCA, ceruloplasmin, copper, cortisol, toxicology, heavy metals
- issues to consider
  - failure to cope, fitness to drive, caregiver capacity and wellbeing, power of attorney, legal will, advanced medical directives, patient and caregiver safety

Table 14. Selected Causes of Major NCD (Dementia)

Etiology	Key Clinical Features	Investigations
PRIMARY DEGENERATIVE		
Alzheimer's disease	Memory impairment Aphasia, apraxia, agnosia	CT or MRI, FDG-PET or SPECT
Dementia with Lewy bodies	Visual hallucinations Parkinsonism Fluctuating cognition REM sleep behaviour disorder Severe neuroleptic sensitivity	CT or MRI, SPECT
Frontotemporal dementia (e.g. Pick's disease)	Behavioural presentation: disinhibition, perseveration, decreased social awareness, mental rigidity, memory relatively spared Language presentation: progressive non-fluent aphasia, semantic dementia	CT or MRI, SPECT
Huntington's disease	Chorea Neuropsychiatric symptoms	Genetic testing
VASCULAR		
Vascular cognitive impairment (previously Multi-infarct dementia)	Bradyphrenia without features of parkinsonism (slow thinking, slow rate of learning, slow gait) Dysexecutive syndrome May be abrupt onset Stepwise deterioration is classic but progressive deterioration is most common	CT or MRI, SPECT
CNS vasculitis	Systemic signs and symptoms of vasculitis	ANA; ANCA; RF CT or MRI Angiography
INFECTIOUS		
Chronic meningitis	Fever, H/A, nausea (triad often absent in cases of chronic meningitis) Meningismus Localizing neurological deficits	CT,MRI, LP
Chronic encephalitis	Fever, H/A	CT or MRI
Chronic abscess	Increased ICP Localizing neurological deficits	CT with contrast, MRI
HIV	See Infectious Diseases, ID27	HIV serology
Creutzfeldt-Jakob disease	Rapidly progressive, myoclonus, akinetic mutism, parkinsonism, or cortical symptoms	EEG, CT or MRI, LP
Syphilis	Ataxia, myoclonus, tabes dorsalis	LP, CT, or MRI VDRL
TRAUMATIC		
Diffuse axonal shear, epidural hematoma, subdural hematoma	Trauma Hx Increased ICP, papilledema Localizing neurological signs	CT, MRI

Sensitivity and Specificity

Tool	Sensitivity	Specificity
MMSE	87%	82%
Clinical Judgment	85%	82%
DSM IV	76%	80%

Vitamin B_{12} Deficiency Symptoms
- Macrocytic anemia, pallor, SOB, fatigue, chest pain, palpitations
- Confusion or change in mental status (if advanced)
- Decreased vibration sense
- Distal numbness and paresthesia
- Weakness with UMN findings
- Diarrhea, anorexia

Major NCD Considerations for Management

ABCDs
Affective disorders, ADLs
Behavioural problems
Caretaker, Cognitive medications and stimulation
Directives, Driving
Sensory enhancement (glasses/hearing aids)

Most common causes of rapidly progressive neurodegenerative dementia are CJD, frontotemporal lobar dementia, tauopathies, diffuse Lewy body disease, and AD

Features of Early Major NCD vs. Normal Aging

Early Signs of Major NCD	Normal Aging
Forgetting the names of close relations	Forgetting the names of acquaintances
Increased frequency of forgetting	Briefly forgetting part of an experience
Repeating phrases/ stories in the same conversation	Not putting away things properly
Unpredictable mood changes	Mood changes in response to appropriate causes
Decreased interest in activities and difficulty making choices	Changes in usual interests

Table 14. Selected Causes of Major NCD (Dementia)

Etiology	Key Clinical Features	Investigations
RHEUMATOLOGIC		
SLE	See Rheumatology, RH11	MRI ANA, anti-dsDNA
NEOPLASTIC		
Primary or secondary brain tumour (metastasis), paraneoplastic encephalitis	Increased ICP Localizing neurological signs Systemic symptoms of cancer	CT with contrast MRI Paraneoplastic antibodies
OTHER		
Normal pressure hydrocephalus	Gait disturbances Urinary incontinence See Neurosurgery, NS9	CT or MRI, large volume LP

Cholinesterase Inhibitors for Dementia with Lewy Bodies (DLB), Parkinson's Disease Dementia (PDD) and Cognitive Impairment in Parkinson's Disease (CIND-PD)
Cochrane DB Syst Rev 2012;3:CD006504
Purpose: To assess the efficacy of treatment with cholinesterase inhibitors in DLB, PDD, and CIND-PD.
Methods: Review of articles from databases including MEDLINE, EMBASE, PsychINFO, and CINAHL.
Results: The six trials (n=1236) included demonstrated therapeutic benefit of cholinesterase inhibitors for global assessment, cognitive function, behavioural disturbance, and activities of daily living. Cholinesterase inhibitors were associated with increased adverse events (OR 1.64) and drop out (OR 1.94). Adverse events were more common with rivastigmine but not with donepezil. Fewer deaths occurred in the treatment group (OR 0.28).
Conclusion: Current evidence supports use of cholinesterase inhibitors for patients with PDD, but its role in DLB and CIND-PD is still unclear.

Major or Mild Neurocognitive Dementia due to Alzheimer's Disease

- see Psychiatry, PS23

Definition

- beyond criterion for NCD, the core features of AD include an insidious onset and gradual progression of cognitive and behavioural symptoms
- typical presentation: amnestic
  - mild phase: impairment in memory and learning sometimes accompanied with deficits in executive function
  - moderate-severe phase: visuoconstructional/perceptual-motor ability and language may also be impaired
  - social cognition tends to be preserved until late in the course of the disease
- atypical nonamnestic presentation (one of the following):
  1. language: aphasia, word-finding difficulty
  2. visuospatial: object agnosia, prosopagnosia, simultanagnosia, alexia, limb apraxia
  3. executive: reasoning, judgment, and problem-solving are affected

4 As and one D of AD
Anterograde amnesia
Aphasia
Apraxia
Agnosia
Disturbance in executive function
(Anterograde amnesia plus at least one of the other features is required for AD diagnosis)

Pathophysiology

- genetic factors
  - minority (<1%) of AD cases are familial (autosomal dominant), associated with early onset AD (<65 yr)
  - 3 major genes, responsible for 5-10% of early onset AD cases, for autosomal dominant AD have been identified:
  - amyloid precursor protein (chromosome 21), presenilin 1 (chromosome 14), presenilin 2 (chromosome 1)
  - the ε4 polymorphism of APOE is a susceptibility genotype (ε2 is protective)
  - note: APOE cannot serve as a diagnostic marker because it is only a risk factor and neither necessary nor sufficient for disease occurrence
- pathology (not necessarily specific for AD)
  - gross pathology
  - diffuse cortical atrophy, especially frontal, parietal, and temporal lobes (hippocampi)
  - microscopic pathology
  - senile β-amyloid plaques (extracellular deposits of amyloid in the grey matter of the brain)
  - loss of synapses
  - neurofibrillary tangles (intracytoplasmic paired helical filaments with amyloid and hyperphosphorylated tau protein)
  - loss of cholinergic neurons in the nucleus basalis of Meynert that project diffusely throughout the cortex
  - biochemical pathology
  - 50-90% reduction in action of choline acetyltransferase

Down syndrome (trisomy 21) predisposes to early onset of AD (i.e. age 40) due to three copies of the amyloid precursor protein on chromosome 21

Epidemiology

- 1/12 of population 65-75 yr
- up to 1/3 population >85 yr
- very rare <65 yr
- accounts for 60-90% of all dementias (depending on setting and diagnostic criteria)

Risk Factors

- age is the greatest risk factor
- genetic susceptibility polymorphism: APOE ε4 increases risk and decreases age of onset
- other factors include: TBI, FHx, Down syndrome, low education, and vascular risk factors (e.g. smoking, HTN, hypercholesterolemia, DM)

Clinical Features
- cognitive impairment
  - memory impairment for newly acquired information (early)
  - deficits in language, abstract reasoning, and executive function
- behavioural and psychiatric manifestations (80% of those with major NCD)
  - mild NCD: major depressive disorder and/or apathy
  - major NCD: psychosis, irritability, agitation, combativeness, and wandering
- motor manifestations (late)
  - gait disturbance, dysphagia, incontinence, myoclonus, and seizures

Investigations
- perform investigations to rule out other potentially reversible causes of dementia
- EEG: usually normal in mild-moderate stages, slow waves in moderate-advanced stages. May observe generalized slowing (nonspecific)
- MRI: preferential atrophy of the hippocampi and precuneus of the parietal lobe; dilatation of lateral ventricles; widening of cortical sulci
- SPECT: hypoperfusion in temporal and parietal lobes
- PET imaging using Pittsburgh compound B (PIB) as a tracer enables imaging of β-amyloid plaque in neuronal tissue
  - FDG-PET can be used to identify regional patterns of cortical hypometabolism and can be helpful to distinguish AD from other causes of dementia (e.g. FTD, DLB)
- LP: β-amyloid protein can be measured in CSF
- Note: common investigations in a clinical setting include ruling out reversible causes with bloodwork, CSF studies, and MRI brain ± EEG. The remainder of the tests are less frequently done or done so in a research setting

Treatment
- **acetylcholinesterase inhibitors** (donepezil, rivastigmine, galantamine) slow the decline in cognitive function
  - do not prolong life expectancy but reduce morbidity
  - relative contraindications: bradycardia, heart block, arrhythmia, CHF, CAD, asthma, COPD, ulcers, or risk factors for ulcers and/or GI bleeding
  - galantamine contraindication: hepatic/renal impairment
- **NMDA-receptor antagonist** (memantine) that has some benefits in moderate-to-severe AD (i.e. MMSE <17)
- **combination therapy** (acetylcholinesterase inhibitor + NMDA antagonist) is most effective in reducing morbidity
- behavioural symptom management
  1. pharmacologic
     - low dose neuroleptics for agitation (neuroleptics may worsen cognitive decline)
     - trazodone for sleep disturbance
     - antidepressants (SSRIs)
  2. non-pharmacologic
     - redirection
     - explore inciting factors for behaviour and modify behaviour of patient or caregiver
     - family support and daycare facilities

Prognosis
- mean duration of survival after diagnosis is approximately 10 yr, reflecting the advanced age of the majority of individuals rather than the course of the disease
- death commonly results from aspiration

Vitamin E and Donepezil for the Treatment of Mild Cognitive Impairment
NEJM 2005;352:2379-88
Purpose: To investigate the efficacy of vitamin E or donepezil in slowing the progression of AD in patients with mild cognitive impairment.
Methods: Patients with the amnestic subtype of mild cognitive impairment were randomly assigned to receive vitamin E (2000 IU daily), donepezil (10 mg daily), or placebo for 3 yr.
Results: Donepezil, but not vitamin E, reduced the likelihood of progression to AD during the first 12 mo (P=0.04), but neither donepezil nor vitamin E significantly reduced the likelihood of progression to AD after 3 yr.
Conclusion: Although donepezil reduced the rate of progression to AD during the first 12 mo, it had no significant effect after 3 yr.

See Landmark Neurology Trial table for more information on the CATIE-AD trial. The trial examined the effects of time and treatment on neuropsychological functioning during the Clinical Antipsychotic Trials of the Intervention Effectiveness-Alzheimer's Disease study.

Major or Mild Neurocognitive Dementia with Lewy Bodies (formerly Dementia with Lewy Bodies)

Definition
- progressive cognitive impairment; early changes in attention, executive, and visuospatial function, recurrent complex visual hallucinations

Clinical Features
- core diagnostic features (probable DLB must have ≥2 core features, possible DLB must have ≥1 core feature):
  - fluctuating cognition with pronounced variations in attention and alertness
  - recurrent visual hallucinations, that are well formed and detailed
  - ≥1 features of parkinsonism (bradykinesia, rest tremor, or rigidity) with onset subsequent to development of cognitive decline
  - REM sleep behaviour disorder
- suggestive/supportive features
  - severe sensitivity to neuroleptic medications (rigidity, neuroleptic malignant syndrome, extrapyramidal symptoms)
  - repeated falls, syncope, or transient episodes of unexplained loss of consciousness
  - auditory or other non-visual hallucinations, systematic delusions, and depression

Etiology and Pathogenesis
- Lewy bodies (eosinophilic cytoplasmic inclusions) found in both cortical and subcortical structures
- mixed DLB and AD pathology is common

Investigations
- indicative
  - SPECT/PET: low striatal dopamine transporter uptake
- supportive
  - CT/MRI: relative preservation of medial temporal structures
  - SPECT/PET: generalized low uptake with occipital atrophy
  - 123-I-metaiodobenzylguanidine myocardial scintigraphy: low uptake
  - EEG: prominent slow wave activity with temporal lobe transient sharp waves

Epidemiology
- 0.1-5% of the general elderly population
- Lewy bodies are present in 20-35% of all dementia cases (more common in males)

Treatment
- only symptomatic treatments available
- cognitive symptoms: acetylcholinesterase inhibitors (e.g. donepezil and rivastigmine)
- REM sleep behaviour disorder: melatonin, clonazepam (use with caution in patients with cognitive impairment and gait disorders)

Prognosis
- average duration of survival 5-7 yr

Major or Mild Frontotemporal Neurocognitive Dementia (formerly Frontotemporal Dementia)

Definition
- group of disorders caused by progressive frontal or temporal lobes atrophy
  - deficits in executive function (e.g. poor mental flexibility, abstract reasoning, response inhibition, planning/organization, increased distractibility) with relative sparing of learning, memory, and perceptual-motor function
- "probable" is distinguished from "possible" frontotemporal NCD by:
  - Family history or genetic testing: evidence of causative frontotemporal NCD genetic mutation
  - CT/MRI: evidence of disproportionate frontal and/or anterior temporal atrophy
  - SPECT/PET: evidence of frontal and/or anterior temporal hypoperfusion or hypometabolism

Behavioural Variant FTD
- most common variant
- typically early symptom presentation (i.e. within the first 3 yr)
- at least 3/5 of the following symptoms must be present and persistent/recurrent:
  - behavioural disinhibition (socially inappropriate behaviour, impulsive, careless)
  - apathy or inertia (decreased initiation or continuation of behaviour, requiring cues/prompts, less likely to initiate or sustain conversations)
  - loss of sympathy or empathy (diminished response to others' needs/feelings, social interest)
  - preservative, stereotyped, or compulsive/ritualistic behaviour
  - hyperorality and dietary changes (binge eating, increased consumption of EtOH/cigarettes or inedible objects)

Primary Progressive Aphasia (PPA)
- prominent decline in language ability, in the form of speech production, word finding, object naming, grammar, or word comprehension
- three subtypes
  - nonfluent/agrammatic variant PPA (NFAV-PPA) or progressive nonfluent aphasia (PNFA): non-fluent, laboured articulation/speech, anomia, preserved single word comprehension, word-finding deficit, impaired repetition
  - semantic variant PPA (SV-PPA) or semantic dementia (SD): fluent, normal rate, anomia, impaired single word comprehension, intact repetition, use words of generalization ("thing") or supraordinate categories ("animal" for "dog")
  - logopenic progressive aphasia (LPA): naming difficulty and impaired repetition

FTD Movement Disorders
- corticobasal degeneration (CBD) (see *Parkinson's Disease, N33*)
- progressive supranuclear palsy (PSP) (see *Parkinson's Disease, N33*)

Etiology and Pathogenesis
- genetic/familial component (40% have family history of early onset NCD)
- genetic variants: MAPT gene (tau), PGRN gene (progranulin), VCP gene, TARDBP gene (TDP-43), CHMP2D gene, C9ORF72 gene (associated with FTD-ALS)
- gross changes: frontal and anterior temporal lobe atrophy, cortical thinning, possible ventricular enlargement

- histological changes: gliosis, swollen neurons, microvacuolation, inclusion bodies in neurons/glia (Tau or TDP-43)

Epidemiology
- 4th most common cause of dementia (5% of all dementia cases)
- common cause of early-onset NCD in individuals <65 yr

Prognosis
- median survival being 6-11 yr after symptoms onset and 3-4 yr after diagnosis
- survival is shorter and decline is faster than in typical AD

Major or Mild Vascular Neurocognitive Dementia

Definition
- CVD as the dominant if not exclusive pathology that accounts for the cognitive deficits
- vascular etiology suggested by one of the following:
  - onset of cognitive deficits is temporally related to one or more cerebrovascular events
  - for mild vascular NCD: history of a single stroke or extensive white matter disease is sufficient
  - for major vascular NCD: history of two or more strokes, a strategically placed stroke, or a combination
  - evidence for decline is prominent in complex attention (including processing speed) and frontal-executive function
- neuroimaging evidence of CVD:
  - one or more large vessel infarct or hemorrhage
  - a strategically placed single infarct or hemorrhage (e.g. angular gyrus, thalamus, basal forebrain)
  - two or more lacunar infarcts outside the brainstem
  - extensive and confluent white matter lesions
- associated features supporting diagnosis: personality and mood changes, abulia, depression, emotional lability, and psychomotor slowing

Etiology and Pathogenesis
- risk factors: same as CVD (e.g. HTN, DM, smoking, obesity, high cholesterol levels, high homocysteine levels, other risk factors for atherosclerosis, atrial fibrillation, and conditions increasing risk of cerebral emboli)
- major or mild vascular NCD with gradual onset and slow progression is generally due to small vessel disease leading to lesions in white matter, basal ganglia, and/or thalamus
- cognitive deficits can be attributed to disruption of cortical-subcortical circuits

Epidemiology
- second most common cause of NCD
- prevalence estimates for vascular dementia/NCD range from 0.2-13% (by age 70), 16% (ages ≥80) to 44.6% (ages ≥90)
- higher prevalence in African Americans
- prevalence higher in males than in females

Creutzfeldt-Jakob Disease

Definition
- rare degenerative, fatal brain disorder caused by prion proteins causing spongiform changes, astrocytosis, and neuronal loss
  - rapidly progressive and common features include cognitive impairment, myoclonus, ataxia, akinetic mutism, weakness, visual changes, etc.
- most common forms are sporadic (85%), hereditary (5-10%), and acquired (<1%)

Prion proteins have a normal form and an infectious form, which results from conversion of the protein from α-helix (normal) to β-pleated sheet (abnormal); these abnormally folded proteins aggregate leading to neuronal loss

Investigations
- CSF analysis, MRI brain (cortical (i.e. cortical ribbon sign) and/or subcortical (i.e. hockey stick sign) FLAIR changes), EEG (periodic complexes), real-time quaking-induced conversion
- definitive diagnosis is by brain biopsy

Treatment
- symptomatic management of seizures and movement disorders, and neuropsychiatric symptoms but there is no known cure for CJD

Aphasia

Definition

- an acquired disturbance of language characterized by errors in language production, writing, comprehension, or reading

Relevant Neuroanatomy

- Broca's area (posterior inferior frontal lobe) is involved in language production (expressive)
- Wernicke's area (posterior superior temporal lobe) is involved in comprehension of language (receptive)
- angular gyrus is responsible for relaying written visual stimuli to Wernicke's area for reading comprehension
- arcuate fasciculus association bundle connects Wernicke's and Broca's areas

Assessment of Language

- assessment of context
  - handedness (writing, drawing, toothbrush, scissors), education level, native language, learning difficulties
- assessment of aphasia
  - spontaneous speech (fluency, paraphasias, repetition, naming, writing, neologism, comprehension – auditory and reading)

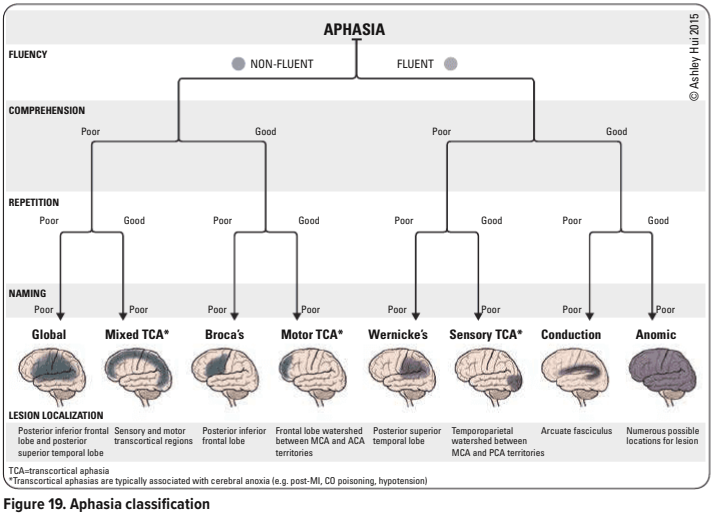

Figure 19. Aphasia classification

>99% of right-handed people have left hemisphere language representation
70% of left-handed people have left hemisphere language representation, 15% have right hemisphere representation, and 15% have bilateral representation

Types of Paraphasias
Semantic (e.g. "chair" for "table")
Phonemic (e.g. "clable" for "table")

Aphasia localizes the lesion to the dominant cerebral hemisphere

Apraxia

Definition

- inability to perform skilled voluntary motor sequences that cannot be accounted for by weakness, ataxia, sensory loss, impaired comprehension, or inattention

Clinicopathological Correlations

Table 15. Apraxia

	Description	Tests	Hemispheres
Ideomotor	Inability to perform skilled learned motor sequences	Blowing out a match, combing one's hair	Left
Ideational	Inability to sequence actions	Preparing and mailing an envelope	Right and left
Constructional*	Inability to draw or construct	Copying a figure	Right and left
Dressing*	Inability to dress	Dressing	Right

*Refers specifically to the inability to carry out the learned movements involved in construction, drawing, or dressing; not merely the inability to construct, draw, or dress. Many skills aside from praxis are needed to carry out these tasks.

Agnosia

Definition

- inability to recognize the significance of sensory stimuli in the presence of intact sensation and naming

Clinicopathological Correlations

Table 16. Agnosias

	Description	Lesion
Apperceptive Visual Agnosia	No visual defect but inability to recognize objects	Bilateral temporo-occipital cortex
Associative Visual Agnosia	Inability to name an object presented visually, 2º to disconnect between visual cortex and language areas Visual perception is intact as demonstrated by visual matching	Bilateral inferior temporo-occipital junction
Prosopagnosia	Inability to recognize familiar faces in the presence of intact visual perception and intact auditory recognition	Bilateral temporo-occipital areas or right inferior temporo-occipital region
Colour Agnosia	Inability to perceive colour	Bilateral inferior temporo-occipital lesions
Impaired Stereognosis	Inability to identify objects by touch	Anterior parietal lobe in the hemisphere opposite to the affected hand
Finger Agnosia	Inability to recognize, name, and point to individual fingers	Dominant hemisphere parietal-occipital lesions

Lesions of the dominant parietal lobe are characterized by Gerstmann's syndrome: acalculia, agraphia, finger agnosia, and left-right disorientation

Lesions of the non-dominant parietal lobe are characterized by neglect, anosognosia, and asomatognosia

Cortical sensory loss (graphesthesia, astereognosis, impaired 2-point discrimination, and extinction) can be seen with left or right parietal lesions

Mild Traumatic Brain Injury

Definition

- mild TBI = concussion
- trauma-induced transient alteration in mental status that may involve loss of consciousness
- hallmark symptoms: confusion and amnesia, which may occur within minutes
- loss of consciousness (if present) less than 30 min, initial GCS between 13-15, post-traumatic amnesia <24 h

Extent of retrograde amnesia correlates with severity of injury
Regained from most distant to recent memories

Epidemiology

- 75% of TBIs are estimated to be mild; the remainder are moderate or severe (see Neurosurgery, *Brain Injury*, NS37and Emergency Medicine, ER9)
- highest rates in children 0-4 yr, adolescents 15-19 yr, and elderly >65 yr

Clinical Features

- impairments following mild TBI
  - physical: headache, sleep disturbance (hypersomnia or insomnia), nausea, vomiting, and blurred vision, photophobia, phonophobia, dizziness
  - cognitive dysfunction: attentional impairment, slowed reaction time, drowsiness, amnesia, confusion, executive function impairment
  - emotion and behaviour: impulsivity, irritability, depression
- severe concussion: may precipitate seizure, bradycardia, hypotension, sluggish pupils
- associated conditions: brain contusion, diffuse axonal injury, C-spine injury

Investigations

- neurological exam to identify focal neurologic deficits
- neurocognitive assessment
  - simple orientation questions are inadequate to detect cognitive changes
  - initial assessment of severity is determined by GCS
    - mild: 13-15, moderate: 9-12, severe: 3-8
  - sideline evaluation: Standardized Assessment of Concussion, Westmead Post-Traumatic Amnesia Scale, Sport Concussion Assessment Tool
- neuroimaging
  - x-ray skull: not indicated for routine evaluation of mild TBI
  - CT head as indicated by Canadian CT Head Rules
  - MRI not indicated in initial evaluation; consider if continued or worsening symptoms despite normal CT

Treatment

- minimum hourly clinical observations until at least 4 h post injury
- hospitalization if CT is abnormal, or if CT is normal but symptoms not improving at 4-6 h post injury
- early rehabilitation to maximize outcomes
  - occupational therapy (OT), physical therapy (PT), speech-language pathology (SLP), vestibular therapy, driving, therapeutic recreation, sleep hygiene
- pharmacological management of headaches, pain, depression
- cognitive behavioural therapy, relaxation therapy
- follow Return to Play guidelines (www.thinkfirst.ca)

Prognosis

- most recover from mild TBI with minimal treatment, but some experience long-term consequences
- patients with a previous concussion are at increased risk of subsequent concussions and cumulative brain injury
- repeat TBI can lead to life threatening cerebral edema (controversially known as second impact syndrome) or permanent impairment
- sequelae include:
  - post-concussion syndrome: dizziness, headache, neuropsychiatric symptoms, cognitive impairment (usually resolves within wk to mo)
  - post-traumatic headaches: begin within 7 d of injury
  - post-traumatic epilepsy: approximately 2% risk post-mild TBI; prophylactic anticonvulsants are not effective
  - post-traumatic vertigo

Neuro-Oncology

Paraneoplastic Syndromes

- see Endocrinology, E56

Tumours of the Nervous System

- see Neurosurgery, NS12

Movement Disorders

Basal Ganglia

- formed by the caudate, putamen, globus pallidus, subthalamic nucleus, and substantia nigra
- input from cerebral cortex, output to thalamus
- direct pathway: promotes movement, indirect pathway: inhibits movement

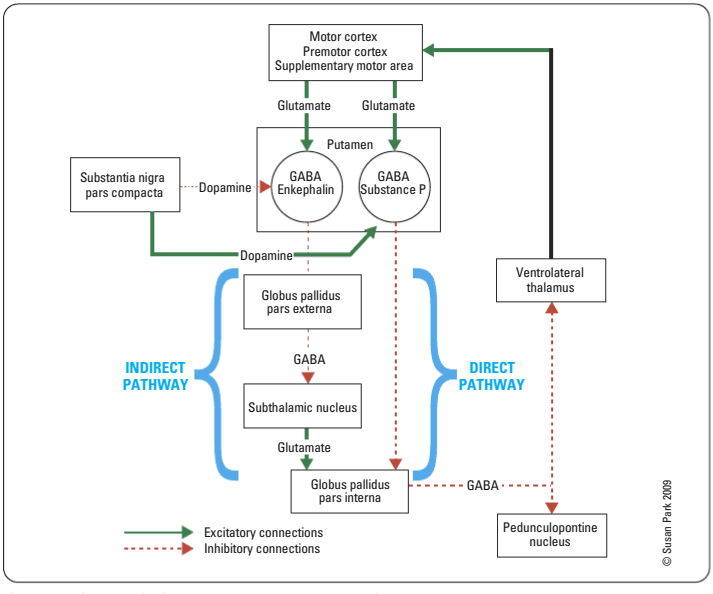

Figure 20. Direct and indirect pathways of the basal ganglia

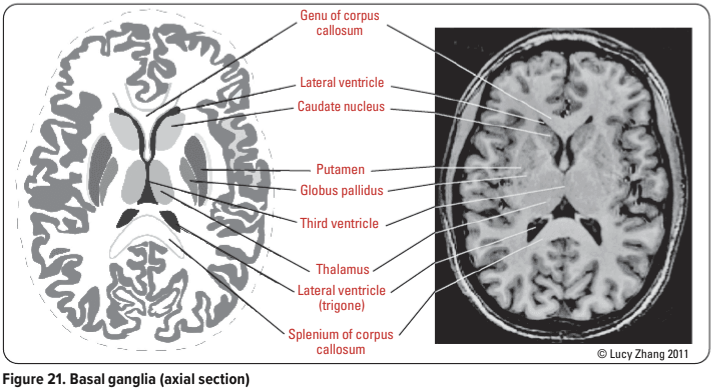

Figure 21. Basal ganglia (axial section)

Signs and Symptoms of Movement Disorders

Table 17. Movement Disorder Definitions

Akathisia	Subjective generalized restlessness relieved by voluntary stereotypic movements (e.g. squirming)
Asterixis	Transient loss of muscle tone (negative myoclonus)
Athetosis	Slow writhing movements, especially distally
Ballism	Large-amplitude, involuntary, flinging movements that are most commonly unilateral (hemiballism)
Bradykinesia	Slow, small amplitude movements
Chorea	Brief, unpredictable, irregular movements, flowing from one body part to another; can appear purposeful in milder forms
Dysdiadochokinesia	Inability to smoothly perform rapidly alternating movements
Dyskinesia	Any involuntary movement, but the term is often used to describe the stereotypical movements that come with long-term neuroleptic use (tardive dyskinesia) or levodopa use (levodopa induced dyskinesia)
Dystonia	Co-contraction of agonist and antagonist muscles causing sustained twisting movements which can be tonic (dystonic postures) or phasic (dystonic movements)
Freezing	Episodes of halted motor action, especially during repetitive actions (e.g. walking)
Myoclonus	Brief muscle group contraction that is either focal, segmental, or generalized
Myokymia	Spontaneous, fine, fascicular contraction of muscle
Stereotypies	Predictable, repetitive, involuntary movements that do not appear to have any purpose (commonly associated with intellectual disability or autism)
Tachykinesia	Acceleration of movements e.g. accelerated walking (festination)
Tics	Stereotyped, nonrhythmic, and brief repetitive actions due to inner urge Can be phonic (vocal) or motor and can be suppressed
Tremor	Rhythmic and involuntary antagonistic muscle alternating/oscillating contractions

In some cases, dystonias may occur only during voluntary movements and sometimes only during specific activities, such as writing, chewing, or speaking (task-specific dystonia)

Hemiballism is most often due to a vascular lesion

Myoclonus can be stimulus-sensitive (induced by sudden noise, movement, light, visual threat, or pinprick)

Tremor

Table 18. Approach to Tremors

	Resting Tremor	Action-Postural Tremor	Action-Intention Tremor
Affected Body Part	Upper limb >jaw>lower limb>head	Upper limb>head>lower limb>tongue	Upper limb>voice>Lower limb
Characteristics	3-6 Hz pill-rolling	6-12 Hz fine tremor	<5 Hz coarse tremor
Worse with Associated Sx	Rest while concentrating "TRAP"	Sustained posture (outstretched arms) ± Autosomal dominant FHx	Finger to nose Cerebellar findings
DDx	PD, parkinsonism, Wilson's disease, mercury poisoning, severe essential tremor	Physiologic, essential tremor, hyperthyroidism, hyperglycemia, heavy metal poisoning, CO poisoning, drug toxicity, sedative/EtOH withdrawal	Cerebellar disorders, Wilson's disease, MS, ASMs, EtOH, sedatives
Treatment	Levodopa/carbidopa (Sinemet®), DBS	Propranolol, primidone, topiramate, and other ASMs, surgery (thalamotomy, DBS)	Treat underlying cause

In a young patient (<45 yr) must do TSH (thyroid disease), ceruloplasmin (Wilson's disease), and CT/MRI (cerebellar disorder) as indicated by type of tremor

Most of the time, essential tremor does not need treatment

Alcohol

Dampens essential tremor

Potentiates intention tremor during abstinence (delirium tremens)

Does not improve resting tremor of PD

Chorea

- HD, HD-like syndromes, neuroacanthocytosis, SLE, antiphospholipid antibodies (APLA) syndrome, Wilson's disease, CVD, tardive dyskinesia, senile chorea, Sydenham's chorea, pregnancy chorea (chorea gravidarum), levodopa-induced dyskinesia

Most common cause of chorea is drug therapy for PD (levodopa-induced dyskinesia)

Dystonia

- **primary dystonia**: familial, sporadic (torticollis, blepharospasm, writer's cramp)
- **dystonia-plus syndromes**: dopa-responsive dystonia, myoclonus-dystonia
- **secondary dystonia**: stroke, CNS tumour, demyelination, drugs/toxins (L-dopa, neuroleptics, anticonvulsants, Mn, CO, cyanide, methanol)
- **heredodegenerative dystonias**: Parkinsonian disorders, Wilson's disease, HD

Myoclonus

- **physiologic myoclonus**: hiccups, nocturnal myoclonus
- **essential myoclonus**: myoclonus-dystonia with minimal or no occurrence of dystonia
- **epileptic myoclonus**
- **symptomatic myoclonus**
- **degenerative disorders**: Wilson's disease, HD, corticobasal degeneration
- **infectious disorders**: CJD, viral encephalitis, AIDS-dementia complex
- **metabolic disorders**: drug intoxication/withdrawal, hypoglycemia, hyponatremia, hyperglycemic hyperosmolar syndrome, hepatic encephalopathy, uremia, hypoxia
- **focal brain damage**: head injury, stroke, mass

Palatal tremor can result from lesion to the dentato-rubro-olivary tract

Parkinson's Disease

Etiology
- sporadic: combination of oxidative stress to dopaminergic neurons, environmental toxins (e.g. pesticides), accelerated aging, genetics
- familial (10%): autosomal dominant α-synuclein or LRRK2 mutations, autosomal recessive parkin, PINK1, or DJ-1 mutation (juvenile onset)
- MPTP (neurotoxin)

Epidemiology
- prevalence of 0.3% in industrialized countries, but rises with increased age
- second most common neurodegenerative disorder, after AD
- mean age of onset is 60 yr

Associated Factors
- risk: family history, male, head injury, rural living, exposure to certain neurotoxins
- protective: coffee drinking, smoking, estrogen replacement in post-menopausal women

Pathophysiology
- α-synucleinopathy: α-synuclein accumulates intracellularly as Lewy bodies and Lewy neurites leading to neuronal loss
- pathological progression of α-synuclein explains onset clinical features: dorsal motor nucleus of the vagus (medulla) and olfactory bulbs (constipation, anosmia) pons (REM sleep behaviour disorder) midbrain, substantia nigra pars compacta, and cortex (cognitive impairment, hallucinations)
- motor symptoms emerge when 70% loss of dopaminergic neurons in substantia nigra pars compacta → decreased dopamine in striatum → 1. disinhibition of the indirect pathway, and 2. decreased activation of the direct pathway → increased inhibition of cortical motor areas

Clinical Features
- diagnosis is based on clinical features:
  1. **bradykinesia**
     - bradykinesia: slow, small amplitude decrementing movements, fatigue from rapid alternating movements, difficulty initiating movement
  2. **resting tremor or rigidity**
     - resting tremor: typically 4-6 Hz "pill-rolling" tremor, especially in hands
     - cogwheel rigidity: increased muscle tone with superimposed tremor
  3. **asymmetric onset of tremor, rigidity, bradykinesia**
  4. **progressive course**
  5. **other signs and symptoms**
     - hypomimia (reduced facial expression), hypophonia, aprosodia (monotonous speech), dysarthria, micrographia, shuffling gait with decreased arm swing
     - freezing of gait: occurs with walking triggered by initiating stride or barriers/reaching destinations, lasting seconds
     - postural instability: a late finding that presents as falls
     - cognition: bradyphrenia (slow to think/respond), dementia (late finding)
     - behavioural: decreased spontaneous speech, depression, sleep disturbances, anxiety
     - autonomic: constipation, urinary dysfunction (nocturia, urgency, frequency), sexual dysfunction, orthostatic hypotension, clinostatic HTN
     - sleep: REM sleep behaviour disorder, insomnia, hypersomnolence

Treatment
- **pharmacologic**
  - levodopa/carbidopa (Sinemet®) or levodopa/benserazide (Prolopa®)
  - levodopa is a dopamine precursor, carbidopa/benserazide decrease levodopa peripheral metabolism, decreasing levodopa side effects and increasing its half-life
    - levodopa-related fluctuation: delayed onset of response (affected by mealtime), end-of-dose deterioration ("wearing-off"), random oscillations of on-off symptoms
    - major adverse effect of levodopa: dyskinesia
  - treatment of early PD: levodopa, dopamine agonists, amantadine, MAOI
  - adjuncts: dopamine agonists, MAOI, anticholinergics (especially if prominent tremors), catechol-O-methyltransferase inhibitors
- **surgical** (for patients who respond to levodopa but with debilitating motor fluctuation/dyskinesia)
  - thalamotomy
  - pallidotomy
  - DBS (thalamic, pallidal, subthalamic)
- **psychiatric**
  - SSRIs first line
  - TCAs (beware fall risk, cognitive impairment, and worsening symptoms of PD)

Key Parkinsonian Features

TRAP
Tremor (resting)
Rigidity
Akinesia/bradykinesia
Postural instability

2015 Movement Disorder Society (MDS) Clinical Diagnostic Criteria for PD

"Clinically established PD" requires:

Cardinal Parkinsonism Manifestations: Bradykinesia with either resting tremor or rigidity

2 or more supportive criteria (clear and dramatic beneficial response to dopaminergic therapy, levodopa-induced dyskinesia, rest tremor of a limb, and/or olfactory loss/cardiac sympathetic denervation on MIBG scintigraphy)

No absolute exclusion criteria and no red flags (see full diagnostic criteria - Mov Disord 2015;30:1591-601)

Consider an Alternative Diagnosis if Atypical Parkinsonism

Poor response to levodopa

Abrupt onset of symptoms

Rapid progression

Early falls

Early autonomic dysfunction

Symmetric symptoms at onset

Early age of onset (<50 yr)

Early cognitive impairment

FHx of psychiatric disorders and/or dementia

Recent diagnosis of psychiatric disease

History of encephalitis

Unusual toxin exposure

Extensive travel history

Other Parkinsonian Disorders

- NCD with Lewy bodies: see *Behavioural Neurology, N21*
- progressive supranuclear palsy (PSP): tauopathy; limited vertical gaze (downgaze more specific, can be overcome by the oculocephalic reflex), early postural instability (frequent falls, wide-based unsteady gait), axial rigidity, akinesia, dysarthria, dysphagia; little or no response to levodopa
- corticobasal syndrome: tauopathy; unilateral parkinsonism, dystonia/myoclonus, and apraxia ± "alien limbs" phenomenon; ± progressive non-fluent aphasia; unlikely to respond to levodopa
- MSA: synucleinopathy; cerebellar predominant (MSA-C) or parkinsonism predominant (MSA-P); early autonomic dysfunction (urinary incontinence or orthostatic hypotension)
- vascular parkinsonism: multi-infarct presentation with gait instability and lower body parkinsonism; stepwise decline over time; less likely associated with tremor

Huntington's Disease

Etiology and Pathogenesis

- genetics: autosomal dominant cytosine-adenine-guanine (CAG) repeats in HTT gene on chromosome 4, which leads to accumulation of defective protein in neurons; autosomal dominant inheritance; genetic anticipation where CAG repeats increase in size with subsequent generations
- pathology: global cerebral atrophy, especially affecting the striatum, leading to increased activity of the direct pathway, and decreased activity of the indirect pathway

Epidemiology

- North American prevalence 4-8 in 100000
- mean age of onset 35-44 yr, but varies with degree of anticipation from 5-70 yr

Clinical Features

- typical progression: insidious onset with clumsiness, fidgetiness, and irritability, progressing over 15 yr to major NCD, psychosis, and chorea
  - major NCD: progressive memory impairment and loss of intellectual capacity
  - chorea: begins as movement of eyebrows and forehead, shrugging of shoulders, and parakinesia (pseudo-purposeful movement to mask involuntary limb jerking)
  - progresses to dance-like or ballism, and in late stage is replaced by dystonia and rigidity
  - mood changes: irritability, depression, anhedonia, impulsivity, bouts of violence
- Juvenile-onset HD (Westphal variant) characterized by parkinsonism, dystonia, rigidity, seizures

Investigations

- MRI
  - enlarged ventricles, atrophy of cerebral cortex, and caudate nucleus
- genetic testing
  - CAG trinucleotide repeats in HTT on chromosome 4p16.3
  - CAG repeat sizes that result in meiotic instability (27-35 repeats), reduced disease penetrance (36-39 repeats), and full disease penetrance (≥40 repeats)

Treatment

- no disease-modifying treatment
- psychiatric symptoms: antidepressants and antipsychotics
- chorea: tetrabenazine, amantadine, and neuroleptics
- dystonia: botulinum toxin (for focal dystonia)

Wilson's Disease

- see Gastroenterology, G37

Dystonia

Epidemiology

- 3rd most common movement disorder after PD and essential tremor

Clinical Features

- abnormal posturing, sustained or intermittent twitching movements caused by co-contraction of agonist and antagonist muscles
- symptoms exacerbated by fatigue, stress, and emotions; relieved by sleep or specific tactile/proprioceptive stimuli (sensory tricks, e.g. placing hand on face for cervical dystonia)
- more likely to be progressive and generalized if younger onset or leg dystonia

Dopamine Agonist Therapy in Early Parkinson's Disease
Cochrane DB Syst Rev 2009;2:CD006564
Study: Meta-analysis of trials of dopamine agonists in early PD.
Results: Twenty-nine trials were included (n=5247). Dopamine agonists were found to have decreased motor side effects (dyskinesia (OR 0.51), dystonia (OR 0.64), motor **fluctuations** (OR 0.75), but provided poorer symptom control compared to levodopa. Also, other side effects were increased (constipation (OR 1.59), hallucinations (OR 1.69), dizziness (OR 1.45)).
Conclusion: Dopamine agonists have fewer motor side effects than levodopa, but provide worse symptom control and increased rate of other side effects.

Treatment
- local medical: botulinum toxin
- systemic medical: anticholinergics (trihexyphenidyl, benztropine), muscle relaxants (baclofen), benzodiazepines, dopamine depletors (tetrabenazine), dopamine for dopa-responsive dystonia
- surgical: DBS or denervation of affected muscle

Tic Disorders

Definition
- sudden, rapid, recurrent, nonrhythmic, stereotyped motor movement or vocalization
- common criteria
  - onset <18 yr
  - tics may wax and wane in frequency but have persisted for an extended period of time
  - disturbance is not attributable to the physiological effects of a substance or another medical condition

Classification
- **Tourette's syndrome**: multiple motor and ≥1 vocal tics that have persisted for >1 yr since onset
- **persistent (chronic) motor or vocal tic disorder**: single or multiple motor or vocal tics (but not both motor and vocal) that have persisted for >1 yr since onset
- **provisional tic disorder**: single or multiple motor and/or vocal tics present for <1 yr since first tic onset
- **other specified or unspecified tic disorder**: symptoms characteristic of a tic disorder but do not meet full criteria
- **secondary tic disorders**: encephalitis, CJD, Sydenham's chorea, head trauma, drugs (stimulants, levodopa), intellectual disability syndromes
- **neurodegenerative diseases**: neuroacanthocytosis, HD (see *Huntington's Disease, N34*)

Tic Types
- simple tics: short duration (msec)
- complex tics: longer (s), more purposeful and often include a combination of simple tics
- motor tics
  - simple: blinking, head jerking, shoulder shrugging, extension of the extremities
  - dystonic: bruxism (grinding teeth), abdominal tension, sustained mouth opening
  - complex: copropraxia (obscene gestures), echopraxia (imitate gestures), throwing, touching
- vocal tics
  - simple: blowing, coughing, grunting, throat clearing
  - complex: coprolalia (shout obscenities), echolalia (repeat others' phrases), palilalia (repeat own phrases)

Treatment
- indicated if quality of life affected
- mild tics: education, counselling, supportive care, Comprehensive Behavioural Intervention for Tics
- debilitating tics: α-2 adrenergic agonists (guanfacine, clonidine), antipsychotics (e.g. haloperidol, pimozide), botulinum toxin, topiramate, DBS

Tourette's Syndrome

DSM-V Definition
1. presence of both multiple motor and one or more vocal tics at some point during the illness, although not necessarily concurrently
2. tics may wax and wane in frequency but have persisted >1 yr since first tic onset (with no tic-free periods >3 mo)
3. onset <18 yr
4. not due to effect of a substance or another medical condition

Epidemiology
- estimated prevalence among adolescents 3-8 in 1000 school-age children, M:F=2-4:1

Signs and Symptoms
- tics: wide variety that wax and wane in type and severity (see *Tic Disorders – Tic Types*)
  - can be associated with the presence of premonitory feelings or sensations that are relieved by carrying out the tic
  - can be voluntarily suppressed for some time
  - can be worsened by anxiety, excitement, and exhaustion; improved by calm, focused activities
- psychiatric: compulsive behaviour (associated with obsessive-compulsive disorder (OCD) and Attention-Deficit/Hyperactivity Disorder (ADHD)), hyperactive behaviour, "rages," sleep-wake disturbances, or learning disabilities

Treatment
- mild tics: (see *Tic Disorders –Treatment, N35*)
- debilitating tics: (see *Tic Disorders –Treatment, N35*)

Prognosis
- typically begins between ages 4-6
- peak severity occurs between ages 10-12, with a decline in severity during adolescence (50% are tic-free by age 18)
- tic symptoms, however, can manifest similarly in all age groups and across the lifespan

Cerebellar Disorders

Cerebellar Signs and Symptoms
- symptoms ipsilateral to side of lesion
- limb ataxia (if involvement of lateral zone of cerebellar hemisphere)
  - dysmetria (uncoordinated movements, assessed with finger-to-nose and heel-to-shin tests)
  - intention tremor (tremor that worsens at end of goal-directed movement)
  - dysdiadochokinesia (inability to perform rapid alternating movements)
  - hypotonia causing pendular reflexes
  - Holmes rebound phenomenon (exaggerated movement after resistance is removed)
- truncal ataxia (if involvement of cerebellar vermis)
  - wide-based gait
  - inability to perform heel-to-toe (tandem) gait
  - truncal titubation
- nystagmus (often gaze-evoked), hypermetric or hypometric saccades, impaired smooth pursuit
- scanning speech (explosive speech with noticeable pauses and accentuated syllables)

Wernicke-Korsakoff Syndrome

- acute (Wernicke's encephalopathy) and chronic (Korsakoff's psychosis) disorders caused by thiamine (vitamin B1) deficiency, see Psychiatry, PS29
- etiology: alcohol use disorder, gastrointestinal disorders especially malabsorption, surgeries (e.g. gastric bypass), malnutrition, acquired immune deficiency syndrome, hemodialysis, malignancies
- note that alcohol can also cause a cerebellar ataxia separate from thiamine deficiency; this ataxia can be due to cerebellar atrophy or alcohol polyneuropathy

Cerebellar Ataxias

Congenital Ataxias
- early onset non-progressive ataxias associated with various syndromes as well as developmental abnormalities (e.g. Arnold-Chiari malformation, Dandy-Walker cysts)

Hereditary Ataxias
- autosomal recessive: Friedrich's ataxia, ataxia with oculomotor apraxia, ataxia telangiectasia, ataxia with vitamin E deficiency
  - Friedrich's ataxia: prevalence 2 in 100000; typical onset between 8-15 yr
  - signs: gait and limb ataxia, weakness, areflexia, extensor plantar response, impaired proprioception and vibration, dysarthria, nystagmus
  - death in 10-20 yr from cardiomyopathy or kyphoscoliotic pulmonary restriction
- autosomal dominant: most commonly spinocerebellar ataxias (SCAs); 30+ types, most commonly due to CAG repeats
  - signs: ataxia and dysarthria, chorea, polyneuropathy, pyramidal, and/or extrapyramidal features, dementia

Acquired Ataxias
- neurodegeneration: multiple system atrophy, SCAs
- systemic: alcohol, celiac sprue, hypothyroidism, Wilson's, thiamine deficiency, vitamin E deficiency
- toxins: CO, heavy metals, lithium, anticonvulsants, solvents
- vascular: infarct, bleed, basilar migraine
- autoimmune: MS, Miller-Fisher variant of GBS
- primary or secondary neoplasm

Vertigo

- see Otolaryngology, OT12

Motor Neuron Disease

Amyotrophic Lateral Sclerosis

Definition
- progressive neurodegenerative disease that causes UMN and LMN symptoms and is ultimately fatal
- also known as Lou Gehrig's disease

Etiology
- idiopathic (most common), genetic (5-10% familial, most commonly C9orf72 mutation, other mutations include: SOD1, TARDBP)

Pathology
- disorder of lower motor neurons of the spinal cord and cranial nerve motor nuclei, and upper motor neurons of the corticospinal tract

Epidemiology
- 5 in 100000; incidence increases with age

Clinical Features
- UMN symptoms
  - poor dexterity
  - spasticity (spastic gait)
  - hyperreflexia
  - bulbar findings: dysarthria (spastic; strained vocal quality with slow speech), dysphagia, pseudobulbar affect, laryngospasm
- LMN symptoms
  - weakness (of hands, arms, tongue, pharyngeal muscles, lips, eyelids, masseters and pterygoids, diaphragm)
  - muscle atrophy
  - fasciculations
  - muscle cramps
  - bulbar findings: dysarthria (flaccid; slurred and may have a nasal quality) and dysphagia
- cognitive and behavioural dysfunction, FTD (~15%)
- sensory symptoms uncommon (20-30%)

Investigations
- EMG: to assess active and chronic denervation and reinnervation, fasciculations
- NCS: to rule out peripheral neuropathy (e.g. multifocal motor neuropathy with conduction block)
- MRI brain and spine: to exclude alternative diagnoses and evaluate LMN, UMN, and bulbar findings
- genetic testing: to look for pathogenic variants in patients with familial ALS

Treatment
- riluzole (been shown to slow disease progression and prolong survival)
- edaravone (been shown to slow functional decline by 33% in early-stage ALS)
- sodium phenylbutyrate-taurursodiol (PB-TURSO; been shown to slow clinical deterioration)
- symptomatic relief
  - spasticity/cramping: baclofen, tizanidine (Zanaflex®), regular exercise, and physical therapy
  - sialorrhea: TCA (e.g. amitriptyline), sublingual atropine drops, parotid, and/or submandibular Botox® (rare)
  - pseudobulbar affect: dextromethorphan and quinidine, TCA, SSRI
- non-pharmacologic: high caloric diet, ventilatory support (especially BiPAP), early nutritional support (e.g. percutaneous endoscopic gastrostomy tube), rehabilitation (PT, OT, SLP), and psychosocial support

Prognosis
- median survival is 3 yr; death is typically due to respiratory failure

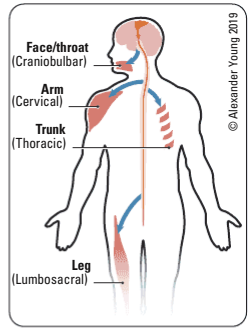

Figure 22. Regions affected by ALS
Adapted from: https://www.mda.org/disease/amyotrophic-lateral-sclerosis/signs-and-symptoms and labels: ALS and Other Motor Neuron Diseases (2017) Lecture by Dr. Aaron Izenberg

Safety and Efficacy of Edaravone in Well Defined Patients with Amyotrophic Lateral Sclerosis: A Randomised, Double-Blind, Placebo-Controlled Trial
Lancet Neurol 2017;16:505-12
Purpose: To assess the safety and efficacy of edaravone in patients with early-stage ALS.
Methods: 137 early-stage ALS patients meeting stringent inclusion criteria were randomly assigned to receive 60 mg IV edaravone or IV saline placebo for 6 cycles (4 wk/cycle with 2 wk on, 2 wk off) for a total treatment duration of 24 wk.
Primary Outcome: Difference in the Revised ALS Functional Rating Scale (ALSFRS-R) score from baseline to 24 wk.
Results: The ALSFRS-R score change was -5.01 (SE 0.64) and -7.50 (0.66) in the edavarone group and placebo, respectively. The between-group least-squares mean difference was 2.49 (SE 0.76, 95% CI 0.99-3.98; P=0.0013), thus favouring edaravone. Adverse events were similar in both groups.
Conclusion: In early-stage ALS patients identified in post-hoc analysis of a previous phase 3 study, edaravone significantly reduced the decline of ALSFRS-R scores.

The only interventions shown to extend survival in ALS are riluzole and use of BiPAP. Edavarone in early ALS can decrease functional decline

Red Flags Inconsistent with ALS
Sensory Sx, predominant pain, bowel or bladder incontinence, extraocular muscle weakness

Denervation on EMG
Fibrillations, positive sharp waves, complex repetitive discharges

Reinnervation on EMG
Increased amplitude and duration of motor units

Other Motor Neuron Diseases

- degenerative
  - **progressive muscular atrophy (progressive bulbar palsy):** only LMN symptoms with asymmetric weakness, later onset than ALS, 5-10% of patients in ALS centres (considered the isolated LMN version of ALS)
  - **primary lateral sclerosis (progressive pseudobulbar palsy):** UMN symptoms, later onset, not fatal, variable disability, 5-10% of patients in ALS centres (considered the isolated UMN version of ALS)
  - **progressive bulbar palsy**: UMN and LMN disorder of cranial muscles, bulbar symptoms
- genetic
  - **spinal muscular atrophy**: pediatric or adult-onset disease with symmetric LMN symptoms (genetic disorder)
  - **spino-bulbar muscular atrophy (Kennedy disease):** speech and swallowing difficulty and limb weakness (X-linked genetic)
- infectious
  - **post-polio syndrome**: muscle weakness usually many years after a poliomyelitis infection
  - **West Nile infection**: residual asymmetric muscle weakness, atrophy

Peripheral Neuropathies

Approach

1. differentiate: motor vs. sensory vs. autonomic vs. mixed
2. pattern of deficit: symmetry; focal vs. diffuse; upper vs. lower limb; CN involvement
3. temporal pattern: acute vs. chronic; relapsing/remitting vs. constant vs. progressive
4. history: PMHx, detailed FHx, exposures (e.g. insects, toxins, sexual, travel), systemic symptoms
5. detailed peripheral neuro exam: LMN findings, differentiate between root and peripheral nerves, cranial nerves, respiratory status

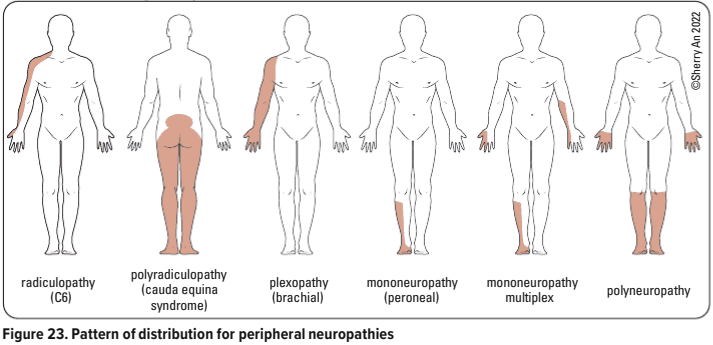

Figure 23. Pattern of distribution for peripheral neuropathies

Classification

- **radiculopathy**: dermatomal sensory deficit and myotomal weakness in distribution of single nerve root (e.g. C7)
  - often due to disc herniation or root compression causing radicular pain
  - little tactile anesthesia, as dermatomes overlap
- **polyradiculopathy**: multiple dermatome sensory deficits and myotomal weakness
  - due to multiple nerve root lesions (e.g. cauda equina syndrome due to lumbosacral roots lesion)
- **plexopathy**: deficit matching distribution of a nerve plexus
  - due to lesion distal to nerve roots but proximal to origin of individual peripheral nerves
  - **brachial plexopathy**
    - upper (C5-C7): LMN Sx of shoulder and upper arm muscles (Erb's palsy)
    - lower (C8-T1): LMN Sx and sensory Sx of forearm and hand (Klumpke's palsy)
    - DDx: trauma, idiopathic neuritis, tumour infiltration, radiation, thoracic outlet syndrome (e.g. cervical rib)
  - **lumbosacral plexopathy** (rare, especially unilateral)
    - DDx: idiopathic neuritis, infarction (e.g. DM), compression
- **mononeuropathy**: single nerve deficit
  - **carpal tunnel syndrome (most common):** compression of median nerve at wrist
    - symptoms: wrist pain, paresthesia first 3 and ½ digits, ± radiation to elbow, worse at night
    - signs: Tinel's sign, Phalen's test, thenar muscle wasting, sensory deficit
    - EMG/NCS: slowing at wrist (both motor and sensory)
    - etiology: entrapment, pregnancy, DM, gammopathy, rheumatoid arthritis, thyroid disease
  - **Bell's palsy (most common cranial neuropathy):** see Otolaryngology, OT22

Diabetic Neuropathies

Peripheral neuropathy: pain or loss of sensation in a stocking-glove distribution (hands and feet affected before arms and legs)

Autonomic neuropathy: tachycardia, anhidrosis, orthostatic hypotension, gastroparesis, GERD, bowel and bladder dysfunction, erectile dysfunction

Mononeuropathy multiplex: nerve infarct or compression

Cranial neuropathy: CN III (pupil sparing) > IV > VI

Lumbosacral plexopathy (i.e. diabetic amyotrophy): unilateral leg pain and weakness, unintentional weight loss

DDx of Demyelinating Neuropathy

GBS, CIDP, paraproteinemia, diphtheria, amiodarone, Charcot-Marie-Tooth (including hereditary neuropathy with liability to pressure palsy), storage diseases, pressure palsy predisposition, paraneoplastic

Tinel's Sign

Tap lightly over the median nerve at the wrist; the patient's symptoms of carpal tunnel will be elicited in a positive test

Phalen's Test

Hold both wrists in forced flexion (with the dorsal surfaces of the hands pressed against each other) for 30-60 s; test is positive if symptoms of carpal tunnel are elicited

Axonal neuropathies have decreased amplitude on NCS; demyelinating neuropathies have decreased conduction velocity on NCS

Ototoxic drugs (e.g. aminoglycosides) should not be given to diabetic patients Sensory neuropathy of the feet prevents these patients from adequately compensating for loss of vestibular function

- **entrapment/compression:** ulnar (compression at elbow), median (at pronator teres), radial (at spiral groove of humerus), obturator (from childbirth), peroneal (due to crossing legs or surgical positioning), posterior tibial (tarsal canal)

- **mononeuropathy multiplex**: subacute involvement of multiple individual peripheral nerves in asymmetric, non-length-dependent manner; often painful
  - must rule out vasculitis or collagen vascular disease; consider MMN (multifocal motor neuropathy) or MADSAM (multifocal acquired demyelinating sensory and motor neuropathy), multiple compressive neuropathies
- **polyneuropathy**: chronic progressive involvement of multiple peripheral nerves in symmetrical, distal-predominant pattern
  - length-dependent, i.e. longest fibres affected first (stocking-glove distribution)
  - sensorimotor, with progression of dysesthesia earlier and weakness later
  - etiology: DM (most common), renal disease, substances, toxins, genetic, SLE, HIV, leprosy, alcohol, vitamin B12 deficiency
  - **CIDP**
    - chronic relapsing sensorimotor polyneuropathy or polyradiculopathy with increased protein in CSF and demyelination (shown on EMG/NCS)
    - course is fluctuating, in contrast with the acute onset of GBS
    - treatment: first-line is prednisone; alternatives are plasmapheresis, IVIG, and azathioprine

Evaluation of Distal Symmetric Polyneuropathy: Role of Laboratory and Genetic Testing
Neurology 2009;72:185-192
Screening Lab Tests: Blood glucose, serum vitamin B12 with metabolites, serum protein immunofixation electrophoresis.
Genetic Testing: Indicated for cryptogenic polyneuropathy exhibiting classic hereditary neuropathy phenotype. Screen for CMT1A duplication/deletion and Cx32 mutations.

Table 19. Differential Diagnosis of Symmetric Polyneuropathy

	Etiology	Mechanism	Course	Modalities	Investigations
Vascular*	PAN	Ischemic	Chronic	S/M	See Rheumatology, RH21
	SLE	Ischemic	Chronic	S/M	See Rheumatology, RH11
	RA	Ischemic	Chronic	S/M	See Rheumatology, RH8
Infectious	HIV	Axonal	Chronic	S/A	HIV serology
	Leprosy	Infiltrative	Acute	S/A	Leprosy serology Nerve biopsy
	Lyme	Axonal	Chronic	M	Lyme serology
Immune+	GBS	Demyelination	Acute	M	LP (↑ protein, no ↑ cells) EMG
	CIDP	Demyelination	Chronic	S/M	LP (↑ protein) EMG
Hereditary	HMSN	Axonal/demyelination	Chronic	S/M	Genetic testing
Neoplastic	Paraneoplastic	Axonal/demyelination	Chronic	S/M	Paraneoplastic antibodies
	Myeloma	Axonal/demyelination	Chronic	S/M	SPEP Skeletal bone survey
	Lymphoma	Axonal	Chronic	M	SPEP Bone marrow biopsy
	Monoclonal gammopathy	Axonal/Demyelination	Chronic	S/M	SPEP Bone marrow biopsy
Toxin	EtOH	Axonal	Sub-acute	S/M	GGT, MCV
	Heavy metals (e.g. lead)	Axonal	Sub-acute	S/M	Urine heavy metals
	Medications	Axonal	Sub-acute	S/M	Drug levels
Metabolic	DM	Ischemic/axonal	Chronic	S/A	Fasting glucose, HbA1c, 2 h OGTT
	Hypothyroidism	Axonal	Chronic	S/M	TSH, T3, T4
	Renal failure	Axonal	Chronic	S/A	Electrolytes, Cr, BUN
Nutritional	B_{12}deficiency	Axonal	Sub-acute	S/M	Vitamin B_{12}
Other	Porphyria	Axonal	Sub-acute	M	Urine porphyrins
	Amyloid	Axonal	Sub-acute to chronic	S/M	SPEP Nerve biopsy

A = autonomic; CIDP = chronic inflammatory demyelinating polyneuropathy; GGT = gamma-glutamyl transferase; HMSN = hereditary motor sensory neuropathy;
M = motor; OGTT = oral glucose tolerance test; PAN = polyarteritis nodosa; RA = rheumatoid arthritis; S = sensory; SLE = systemic lupus erythematosus;
SPEP = serum protein electrophoresis
* Neuropathies of vascular etiology usually present as mononeuropathy multiplex
+ Neuropathies of immune etiology usually present as polyradiculopathy

Guillain-Barré Syndrome

Definition
- acute, rapidly evolving (evolving over 4 wk or less) demyelinating inflammatory polyradiculoneuropathy that often starts in the distal lower limbs and ascends

Etiology
- autoimmune attack and damage to peripheral nerve myelin
- usually preceded by viral/bacterial infections

Signs and Symptoms
- sensory: distal and symmetric paresthesias, loss of proprioception and vibration sense, neuropathic pain
- motor: weakness starting distally in legs and progressing proximally, areflexia
- autonomic: blood pressure dysregulation, arrhythmias, bladder dysfunction

Investigations
- CSF: albuminocytologic dissociation (high protein, normal WBC)
- EMG/NCS: conduction block, differential or focal (motor>sensory) slowing, decreased F-wave, sural sparing

Treatment
- IVIG or plasmapheresis, pain management, monitor vitals and vital capacity

Prognosis
- peak of symptoms at 2-3 wk, plateau or resolution at 4-6 wk
- 5% mortality (higher if require ICU), up to 15% have permanent deficits

In GBS, IVIG and plasmapheresis lead to more rapid improvement, less intensive care, and less ventilation, but do not change mortality or relapse rate

GBS is a neurological emergency due to risk of imminent respiratory failure

The most commonly identified antecedent infection in GBS is *Campylobacter jejuni*

Miller-Fischer Variant of GBS – Triad
Ophthalmoplegia, ataxia, areflexia

Neuromuscular Junction Disorders

Table 20. Common Disorders of the Neuromuscular Junction

	Myasthenia Gravis	Lambert-Eaton	Botulism
Ocular/Bulbar Paresis	+	–	++ (early)
Limb Weakness	+	+	+
Fatigability	+	+	+
Post-Exercise Enhancement	–	+	+
Reflexes	N	↓	↓
Anticholinergic Sx	–	+	++
Sensory Sx	–	–	–
Associated Conditions	Thymoma	Small cell carcinoma	GI signs and symptoms
Repetitive EMG Stimulation	Decremental response	Incremental response	↑ (rapid stimulation) ↓ (slow stimulation)

Neuromuscular Junction Disease

Typically feature prominent fatigability

Fatigability can be tested by holding the arms out or by holding the gaze in the upward position (especially in MG)

Muscle weakness due to fatigability will improve with rest and/or ice

Myasthenia Gravis

Etiology and Pathophysiology
- autoimmune disorder of the neuromusclar junction, commonly associated with acetylcholine receptor antibodies or muscle-specific kinase antibodies
- 15% of patients with MG have associated thymic neoplasia, 85% have thymic hyperplasia

Epidemiology
- bimodal age of onset, 20s (mostly women) and 60s (mostly men)

Clinical Features
- fatigable, symmetric, or asymmetric weakness without reflex changes, sensory changes, or coordination abnormalities
- ocular (diplopia/ptosis), bulbar (dysarthria/dysphagia), and/or proximal limb weakness
- symptoms may be exacerbated by infection, pregnancy, menses, and various drugs
- respiratory muscle weakness may lead to respiratory failure

Investigations
- repetitive stimulation: decrement in amplitude >10%
- single fibre EMG: shows increased jitter (80-100% sensitivity)
- spirometry: forced vital capacity may be used to monitor adequacy of respiratory effort over time
- acetylcholine receptor antibody assay (50-90% sensitivity); muscle-specific kinase antibody may be used if seronegative for acetylcholine receptor antibody
- CT/MRI chest: screen for thymoma/thymic hyperplasia
- edrophonium (Tensilon®) test: assess for improvement over 2 min following edrophonium injection (no longer performed)

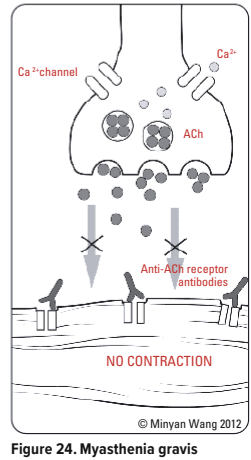

Figure 24. Myasthenia gravis

Treatment
- acetylcholinesterase inhibitors (e.g. pyridostigmine): first line treatment
- corticosteroids (e.g. prednisone): mainstay of treatment if acetylcholinesterase inhibitors not effective
- short-term immunomodulation (e.g. IVIG and plasmapheresis): for crisis
- long-term immunosuppression (e.g. azathioprine, cyclophosphamide, mycophenolate): can be used as steroid-sparing therapy
- newer medications that are more disease specific: Eculizumab (complement inhibitor), Efgartigimod (neonatal Fc receptor blocker)
- thymectomy: option in non-thymomatous acetylcholine receptor antibody-positive generalized MG (85% remission rate)

Prognosis
- 30% eventual spontaneous remission
- with treatment, life expectancy is equal to that of a person without MG, but quality of life may vary

Lambert-Eaton Myasthenic Syndrome

Etiology and Pathophysiology
- autoimmune disorder due to antibodies against presynaptic voltage-gated calcium channels, causing decreased acetylcholine release at the neuromuscular junction
- 50-66% are associated with small cell carcinoma of the lung

Clinical Features
- weakness of skeletal muscles without sensory or coordination abnormalities, proximal and lower muscles more affected
- reflexes are diminished or absent, but increase after active muscle contraction
- bulbar and extraocular muscles affected in 25% (vs. 90% in MG)
- prominent anticholinergic autonomic symptoms (dry mouth>impotence>constipation>blurred vision)

Investigations
- rapid (>10 Hz) repetitive nerve stimulation: incremental response
- anti-P/O-type voltage-gated calcium channel antibodies: are present in 85-95% of patients with LEMS
- EMG: typically normal in LEMS
- edrophonium test: no response
- EMG: incremental response with exercise
- screen for malignancy, especially small cell lung cancer

Treatment
- tumour removal
- increase acetylcholine concentration at synaptic cleft
  - increase acetylcholine release (3,4-diaminopyridine)
  - decrease acetylcholine degradation (pyridostigmine)
- immunomodulation: corticosteroids, plasmapheresis, IVIG

Botulism

Etiology and Pathophysiology
- caused by a toxin produced by spores of Clostridium botulinum bacteria, which can enter through wounds or by ingestion
- infantile botulism is the most common form and is usually from ingestion of honey or corn syrup

Clinical Features
- occur 6-48 h after ingestion
- bilateral cranial neuropathies: ptosis, extraocular muscle weakness, dilated poorly reactive pupils, dysarthria, jaw weakness, dysphagia
- symmetric descending weakness with paralysis and absent/decreased reflexes
- autonomic dysfunction: nausea, orthostatic hypotension, constipation (paralytic ileus), bladder distension
- anticholinergic symptoms: dry mouth, constipation, urinary retention
- pattern of paresis often starts with GI symptoms → extraocular muscle weakness → dysphagia → limbs and respiratory involvement
- without prompt treatment, respiratory muscle weakness can lead to respiratory failure

Investigations
- blood test for toxin, stool culture
- CT/MRI to rule out intracranial lesion (normal in botulism)

Treatment
- botulinum anti-toxin: good prognosis with prompt treatment
- supportive therapy as required (monitor respiratory status and assess need for intubation)

Tensilon® is a drug that inhibits acetylcholinesterase. While it can improve muscle function immediately in MG, it is ineffective in a cholinergic crisis. Although it is no longer available for use, if it is administered, it is crucial to have a crash cart nearby, as respiratory difficulty and/or bradycardia may occur.

Randomized Trial of Thymectomy in Myasthenia Gravis
NEJM 2016;375:511-22
Purpose: To compare the efficacy of thymectomy plus prednisone vs. prednisone alone in the treatment of MG
Methods: 126 patients with generalized nonthymomatous MG (clinical class II-IV disease <5 years duration and elevated acetylcholine receptor antibodies) received extended transsternal thymectomy plus alternate-day prednisone or alternate-day prednisone alone.
Results: Over 3 years, thymectomy was associated with a lower time-weighted average quantitative MG score as compared to prednisone alone (6.15 vs. 8.99, P<0.001), and a lower average requirement for alternate-day prednisone (44 mg vs. 60 mg, P<0.001). Immunosuppression was required by fewer patients in the thymectomy group (17% vs. 48%, P<0.001); they were also hospitalized less frequently for exacerbations (9% vs. 37%, P<0.001).
Conclusion: In patients with nonthymomatous MG, thymectomy improved clinical outcomes.

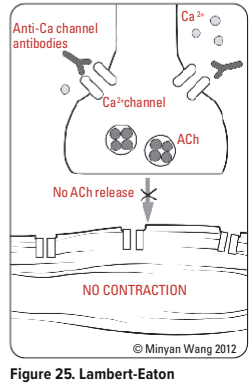

Figure 25. Lambert-Eaton myasthenic syndrome

Myopathies

Table 21. Myopathies

	Etiology	Key Clinical Features	Key Investigations
Inflammatory	Polymyositis (see Rheumatology, RH16)	Proximal muscle weakness Myalgias Nasopharyngeal involvement	↑ creatine kinase Biopsy: endomysial infiltrates, necrosis
	Dermatomyositis (see Rheumatology, RH16)	Proximal muscle weakness Myalgias Characteristic rashes Can be paraneoplastic	↑ creatine kinase Biopsy: perifascicular atrophy
	Sarcoidosis	See Respirology, R16	ACE level Biopsy: granulomas
	Inclusion body myositis	Weak quadriceps and deep finger flexors	↑ creatine kinase Biopsy: inclusion bodies
Endocrine	Thyroid (↑ or ↓) Cushing's syndrome Parathyroid (↑ or ↓)	See Endocrinology, E25	TSH Serum cortisol Calcium panel
Toxic	Medication	Medication or toxin history	Toxicology screen
	Critical illness myopathy	ICU patient Hx steroids and nondepolarizing paralyzing agents Failure to wean from ventilation	Biopsy: selective loss of thick myosin filaments
Infectious	Parasitic, bacterial, or viral	Myalgias Inflammatory myopathy	↑ myoglobin
Hereditary Dystrophy	Duchenne (see Medical Genetics, MG8)	Early onset (Duchenne and Becker)	Dystrophin analysis: absent Genetic testing
	Becker	Progressive proximal muscle weakness Calf pseudohypertrophy	Dystrophin analysis: reduced Genetic testing
	Myotonic dystrophy	Distal myopathy Myotonia Genetic anticipation	Genetic testing
Hereditary Metabolic	McArdle's	Exercise-related myalgias, cramping, and myoglobuminuri	↑ lactate ↑ serum/urinary myoglobin post-exercise
Hereditary Periodic Paralysis	"Channelopathy"	Episodic weakness Normal between attacks	Normal, ↑ or ↓ K^+
Hereditary Mitochondrial	MERRF (mitochondrial encephalopathy with ragged red fibres)	Myoclonus, generalized seizures, dementia, myopathy	Biopsy: ragged red fibres Increased lactate
	MELAS (mitochondrial encephalopathy, lactic acidosis and stroke-like episodes)	Paediatric onset, stroke-like symptoms, episodic vomiting, dementia	
	Kearns Sayre	Progressive ophthalmoplegia, retinal pigment degeneration, cardiac conduction abnormalities	

MELAS: mitochondrial encephalomyopathy, lactic acidosis, and stroke-like episodes; MERRF: mitochondrial encephalomyopathy with ragged red fibres
CK: creatine kinase

Myotonic Dystrophy Type 1

Etiology and Pathophysiology

- unstable trinucleotide (CTG) repeat in myotonic dystrophy kinase gene (protein kinase) at 19q13.3, number of repeats correlates with severity of symptoms, autosomal dominant

Epidemiology

- most common adult muscular dystrophy, prevalence 3-5 in 100000

Clinical Features

- appearance
  - ptosis, facial weakness, frontal baldness (including women), atrophy of facial, levator palpebrae, and masticatory muscles giving a drooping/dull appearance
- physical exam
  - distribution of weakness: distal weaker than proximal (in contrast to other myopathies), steppage gait
  - myotonia: delayed relaxation of muscles after exertion (elicit by tapping on thenar muscles with hammer)
  - cardiac: 90% have conduction defects (1° heart block; atrial arrhythmias)

- respiratory: hypoventilation 2° to muscle weakness
- ocular: subcapsular cataracts, retinal degeneration, decreased intraocular pressure
- other: DM, infertility, testicular atrophy
- EMG: electrical myotonia (waxing and waning discharges, sound like "dive-bomber")

Treatment
- management of myotonia: mexiletine, phenytoin

Prognosis
- varies with age of onset and number of CTG repeats
- no cure, progressive, death usually around 50 yr

Pain Syndromes

Pinprick sensation mediated by Aδ fibres

Pain due to tissue damage is mediated by C fibres

Definitions
- nociceptive pain: pain arising from stimulus causing potential or actual non-neural tissue injury
- neuropathic pain: pain arising from lesion or disease affecting the somatosensory system
- spontaneous pain: unprovoked burning, shooting, or lancinating pain
- paresthesia: spontaneous abnormal non-painful sensation (e.g. tingling)
- dysesthesia: evoked pain with inappropriate quality or excessive quantity
- allodynia: pain response to a non-noxious stimulus
- hyperalgesia: exaggerated pain response to a noxious stimulus

WHO Pain Ladder
Mild Pain: Non-opioid (acetaminophen and/or NSAID) ± adjuvant
Moderate Pain: Opioid for mild to moderate pain (codeine/oxycodone) + non-opioid ± adjuvant
Severe Pain: Opioid for moderate to severe pain (morphine/hydromorphone) + non-opioid ± adjuvant

Non-Pharmacological Management
- physical (PT, acupuncture, chiropractic manipulation, massage)
- psychoeducational (cognitive behavioural therapy,, family therapy, education, psychotherapy)

Pharmacological Management
- combination multi-modal therapy is important
- primary analgesics: acetaminophen, NSAIDs (often used for soft tissue injuries, strains, sprains, headaches, and arthritis), opiates
- adjuvants: antidepressants (TCAs, SSRIs), anticonvulsants (gabapentin, carbamazepine, pregabalin), baclofen, sympatholytics (phenoxybenzamine), α2-adrenergic agonists (clonidine)

Axonal regeneration is directed by intact nerve sheaths. If the nerve sheath is damaged, axons grow without direction, become tangled, and form a neuroma. This can result in ectopic electrical impulses and neuropathic pain

Surgical Management
- peripheral ablation: nerve blocks, facet joint denervation
- direct delivery: implantable morphine pump
- central ablation: stereotactic thalamotomy, spinal tractotomy, or dorsal root entry lesion
- DBS or dorsal column stimulation

Neuropathic Pain

Epidemiology
- affects up to 6% of people (2 million Canadians)

Symptoms and Signs
- hyperalgesia, allodynia
- subjectively described as burning, heat/cold, pricking, electric shock, perception of swelling, numbness
- can be spontaneous or stimulus evoked, distribution may not fall along classical neuro-anatomical lines
- associated issues: sleep difficulty, anxiety/stress/mood alteration

Causes of Neuropathic Pain
- **sympathetic**: complex regional pain syndrome
- **non-sympathetic**: damage to peripheral nerves
  - systemic disease: DM, thyroid disease, renal disease, rheumatoid arthritis, MS
  - nutritional/toxicity: alcoholism, pernicious anemia, chemotherapy
  - infectious: post-herpetic, HIV
  - trauma/compression: nerve entrapment, trigeminal neuralgia, post-surgical, nerve injury, cervical/lumbar radiculopathy, plexopathy
- **central**: abnormal CNS activity
  - phantom limb, post spinal cord injury, post stroke, MS

Treatment
- identify/treat underlying cause
- **pharmacotherapy**
  - stepwise approach (Canadian Pain Society, 2014)
    - 1st line: gabapentinoids, TCA, serotonin and norepinephrine reuptake inhibitor (SNRI)
    - 2nd line: tramadol, opioid analgesics
    - 3rd line: cannabinoids
    - 4th line: methadone, anticonvulsants (lamotrigine, lacosamide), tapentadol, botulinum toxin

- **common non-pharmacologic therapies**
  - neuropsychiatry: cognitive behavioural therapy,, psychotherapy
  - rehabilitation: physiotherapy
- **surgical therapies**: dorsal column neurostimulator, DBS (thalamus)

Trigeminal Neuralgia

Clinical Features
- recurrent episodes of sudden onset, excruciating, unilateral, paroxysmal, shooting "electric" pain in trigeminal root territory (V3>V2>>V1)
- may have normal sensory exam (if abnormal, think of secondary or structural cause)
- pain lasts s/min over d/wk, may remit for wk/mo
- triggers: touching face, eating, talking, cold wind, shaving, applying make-up

Etiology
- classical: compression of trigeminal nerve by tortuous blood vessel (usually superior cerebellar artery)
- secondary: cerebellopontine angle mass, MS
- idiopathic

Epidemiology
- F>M; usually middle-aged or elderly

Diagnosis
- clinical diagnosis
- MRI brain to rule out vascular lesion, intracranial mass, MS

Treatment
- first line: carbamazepine or oxcarbazepine
- second line: baclofen or lamotrigine
- for medically-refractory classical trigeminal neuralgia, consider microvascular decompression
- other neurosurgical options for medically refractory trigeminal neuralgia: trigeminal ganglion percutaneous technique, gamma knife radiosurgery, invasive percutaneous denervation (radiofrequency/glycerol), percutaneous balloon microcompression, microvascular decompression
- narcotics not generally recommended

Postherpetic Neuralgia

Clinical Features
- pain persisting in the region of a cutaneous outbreak of herpes zoster
- constant deep ache or burning, intermittent spontaneous lancinating/jabbing pain, allodynia
- distribution: thoracic, trigeminal, cervical, lumbar, sacral
- associated symptoms: impaired sleep, decreased appetite, decreased libido

Herpes Zoster of Trigeminal Nerve
Typically involves V1 (ophthalmic division)
Hutchinson's Sign
Tip of nose involvement predicts corneal involvement

Etiology and Pathogenesis
- destruction of the sensory ganglion neurons (e.g. dorsal root, trigeminal, or geniculate ganglia) secondary to reactivation of herpes zoster infection

Epidemiology
- incidence in those with zoster increases with age (2% in <60 yr, 19% in >70 yr)
- risk factors: older age, greater acute pain, greater rash severity

Prevention
- varicella zoster vaccine (Varivax®) in childhood reduces incidence of varicella zoster
- herpes zoster vaccine (Zostavax® or Shingrix®) reduces incidences of shingles, postherpetic neuralgia, and other herpetic sequelae
  - Zostavax® is a live vaccine, recommended for patients ≥60 yr
  - Shingrix® is a recombinant vaccine, recommended for patients ≥50 yr (more efficacious than Zostavax®)

Treatment
- medical: TCA (e.g. amitriptyline), anticonvulsants (e.g. pregabalin, gabapentin), analgesia (e.g. opiates, lidocaine patch), intrathecal methylprednisolone, topical capsaicin
  - early treatment of acute herpes zoster with antivirals (longer-acting famciclovir and valacyclovir more effective)
  - treatment of herpes zoster with corticosteroids does not decrease PHN
- surgical: spinal tractotomy, dorsal root entry zone lesion, DBS of thalamus

Painful Diabetic Neuropathy

- see Endocrinology, E16

Approach
- determine if pain is neuropathic or vascular
- more likely neuropathic if pain is present at rest and improves with walking, pain is sharp/tingling, more in feet → calves

Treatment
- level A: pregabalin
- level B: venlafaxine, duloxetine, amitriptyline, gabapentin, valproate, rarely opioids, capsaicin

Complex Regional Pain Syndrome

Definition
- regional pain characterized by pain, swelling, skin changes, and limited range of motion
- often disproportionate to the inciting event (e.g. fracture, stroke), typically lasting 4-6 wk

Diagnosis
- clinical diagnosis consistent with the Budapest Criteria:
    1. continuing regional pain disproportionate to an inciting event
    2. patient must have symptoms in 3 of the 4 categories, and must have signs in 2 of the 4 categories (a sign must be observed at the time of diagnosis):
        - sensory: hyperesthesia and/or allodynia
        - vasomotor: temperature and/or skin colour asymmetry
        - sudomotor/edema: edema, sweating changes, and/or sweating asymmetry
        - motor/trophic: decreased range of motion, motor dysfunction (weakness, tremor, dystonia) and/or trophic changes (hair, skin, nail)
    3. absence of any other diagnosis that would better explain the signs or symptoms
- bone scintigraphy ≤5 mo of symptom onset may support diagnosis (negative test does not rule it out)
- MRI may help rule out other causes of regional pain if indicated

Classification
- type I (reflex sympathetic dystrophy): minor injuries of limb or lesions in remote body areas precede onset of symptoms
- type II (causalgia): injury of peripheral nerves precedes the onset of symptoms

Prevention
- early mobilization after injury/infarction

Treatment
- goal of treatment is to facilitate function
- conservative treatment: education, support groups, PT, OT, smoking cessation
- medical: topical capsaicin; TCA; NSAID; tender point injections with corticosteroid/lidocaine; gabapentin/pregabalin/lamotrigine; calcitonin or bisphosphonates; oral corticosteroids
- surgical: paravertebral sympathetic ganglion blockade
- refer to pain management clinic

Headache

• see Emergency Medicine, ER16 and Family Medicine, FM36

Clinical Approach

• **history**
- pain characteristics: onset, frequency, duration, intensity, location, radiation, other specific features (e.g. worse in AM, worse with bending/coughing/Valsalva)
- associated symptoms: visual changes, change in mental status, N/V, fever, meningismus, photophobia, phonophobia, temporomandibular popping/clicking, jaw claudication, neurological symptoms
- precipitating/alleviating factors (triggering factors, analgesics), medications (especially nitrates, calcium channel blockers, NSAIDs, anticoagulants), PMHx, FHx
- red flags (possible indications for CT scan/further investigation) "SNOOP4": Systemic symptoms or 2° risk factors (fever, weight change, immunocompromised); Neurological symptoms; Onset sudden ('thunderclap'); Older age (especially new-onset headache >50 yr); Pattern change; Positional (worse standing vs. worse supine); Precipitated by Valsalva or cough; Pregnancy-CSVT/IIH/Preeclampsia

• **physical exam**
- vitals (including BP and temperature), Jolt accentuation/Kernig's/Brudzinski's, MSK examination of head and neck
- HEENT: fundi (papilledema, retinal hemorrhages), red eye, temporal artery tenderness, sinus palpation, TMJ
- full neurological exam (including LOC, orientation, pupils (symmetry), and focal neurological deficits)
- red flags: papilledema, altered LOC, fever, meningismus, focal neurological deficits, signs of head trauma

Classification

• primary (cause disability but no brain damage or death)
- tension, migraine, cluster, autonomic cephalgias, short-lasting unilateral neuralgiform headache with conjunctival injection and tearing (SUNCT)

• secondary (medical emergency; can lead to irreversible brain damage or death)
- cervical osteoarthritis, TMJ syndrome, SAH, ICH, stroke, venous sinus thrombosis, meningitis/encephalitis, trauma, increased ICP (space-occupying lesion, malignant HTN, or IIH), temporal arteritis, sinusitis, acute-angle closure glaucoma, pre-eclampsia, post-LP, drugs/toxins (e.g. nitroglycerin use and analgesia withdrawal)

Table 22. Headaches – Selected Primary Types

	Tension-Type	Migraine	Cluster
Prevalence	30-40%	≈10-20%	<1%
Age of Onset	15-40	10-30	20-40
Sex Bias	F>M	F>M	M>F
Family History	None	+++	+
Location	Bilateral frontal Nuchal-occipital	Unilateral > bilateral (in adults especially) Fronto-temporal	Retro-orbital Supra-orbital Temporal
Duration	Minutes-days	Hours-days	10 min-2 h
Onset/Course	Gradual, worse in PM Episodic or chronic	Gradual, worse in PM; can also be acute	Daily attacks for weeks to months; more common early AM or late PM
Quality	Band-like, constant	Pulsating, throbbing	Constant, aching, stabbing
Severity	Mild-moderate (does not wake you up from sleep)	Moderate-severe	Severe (wakes from sleep)
Triggers/Provoking	Depression Anxiety Noise Hunger Sleep deprivation	Noise/light Caffeine/alcohol Hunger Stress Sleep deprivation	Light EtOH
Palliating	Rest	Rest	Walking around
Associated Symptoms	No vomiting No photophobia	N/V Photo/phonophobia/osmophobia ± Aura	Red watery eye Eyelid, forehead swelling Nasal congestion or rhinorrhea Unilateral Horner's
Management	Non-pharmacological: Eliminating known triggers Healthy lifestyle: sleep, diet (protein for breakfast), exercise, hydration, be aware of technology use, vitamin/minerals Psychological counseling Physical modalities (e.g. heat, massage) Pharmacological Vitamins/minerals - Magnesium citrate, Riboflavin (Vitamin B2), Coenzyme Q10, Melatonin if insomnia or difficulty falling asleep Simple analgesics: Tylenol, NSAIDs	Acute Rx/Abortive: NSAIDs Triptans Ergotamine Valproate Anti-emetics CGRP Antagonists Prophylaxis/Preventive: TCA Calcium channel blockers Anticonvulsants β-Blockers Botox	Acute Rx O2 Sumatriptan (nasal or injection) Prophylaxis Verapamil Lithium Methysergide Prednisolone Valproate CGRP antibody

If CT is negative but clinically there is suspicion of SAH or meningitis, perform an LP

Headache DDx

ER VISIT
Eye (acute angle closure glaucoma, sinusitis)
Recurrent/Chronic (migraine, tension, cluster, temporomandibular joint disease, cervical osteoarthritis)
Vascular (SAH, ICH, temporal arteritis)
Infectious (meningitis, encephalitis)
Systemic (anemia, anoxia, CO, pre-eclampsia)
ICP (mass/abscess, HTN encephalopathy, IIH)
Trauma (epidural hematoma, subdural hematoma, concussion)

Trial of Galcanezumab in Prevention of Episodic Cluster Headache
NEJM 2019;381:132-41
Purpose: To investigate the efficacy and safety of galcanezumab as a preventive treatment for cluster headache.
Methods: 106 patients who had min. one attack every other day, min. four total attacks, and max. eight attacks/d, plus a history of cluster headache periods lasting min. 6 wk, received 300 mg galcanezumab or placebo, administered SC at baseline and 1 mo.
Results: After 3 wk, the mean reduction in the weekly frequency of cluster headache attacks was 8.7 attacks in the galcanezumab group vs. 5.2 in the placebo group (difference, 3.5/wk; 95% CI, 0.2-6.7; P=0.04), and the proportion of patients who had a reduction of ≥50% in headache frequency was 71% and 53%, respectively (P=0.046). Incidence of adverse events were similar in both groups.
Conclusion: Galcanezumab reduced the weekly frequency of attacks of episodic cluster headache.

Antiepileptics in Migraine Prophylaxis: An Updated Cochrane Review
Cephalalgia 2015;35:51-62
Purpose: To review the evidence for anticonvulsants in migraine prophylactics.
Study: Systematic meta-analysis of 37 published and 3 unpublished prospective, controlled trials of regular use of anticonvulsants to prevent migraines and/or improve quality of life related to migraines.
Results: Sodium valproate and topiramate were associated with a reduction of 4 d and 1 d of headache per month, respectively, and patients taking either drug were more than 2 times as likely to experience greater than 50% reduction in headache frequency, vs. placebo. Neither drug was associated with undue rates of adverse events, though higher doses of topiramate were associated with increased adverse events. There is insufficient evidence of efficacy with other antiepileptic drugs, including gabapentin, for migraine prophylaxis.
Conclusions: Daily sodium valproate 400 mg and topiramate 50 mg are well tolerated and effective in prophylactic treatment of migraine headache in adults.

Table 23. Prophylactic Management of Migraine Headaches

Class	Drug	Evidence	Contraindications	Side Effects
β-blockers	Propranolol	A	Asthma, DM (mask hypoglycemia) CHF	Fatigue Depression Light-headedness
	Timolol	A		
	Metoprolol	B		
TCA	Amitriptyline	A	Heart disease, glaucoma Avoid in elderly	Sedation Dry mouth Weight gain Light-headedness
	Nortriptyline	C		
CCBs	Flunarizine	A	Depression, obesity	Weight gain, depression, PD (rare)
	Verapamil	B	Heart disease	Weight gain (4.5-9 kg), constipation
AED	Valproate	A	Liver, pancreatic disease	Weight gain, elevated liver enzymes/ hyperammonemia, tremor, alopecia, teratogenic: neural tube defect
	Topiramate	A	Renal disease	Paresthesia, acute angle-closure glaucoma, weight loss, cognitive: memory loss, difficulty concentrating, renal stone (rare)

Table 24. Headaches – Selected Serious but Rare Secondary Types

	Meningeal Irritation	Increased ICP	Temporal Arteritis
Age of Onset	Any age	Any age	>60 yr
Location	Generalized	Any location	Temporal
Onset/Course	Meningitis: hours-days SAH: thunderclap onset	Gradual; worse nocturnal and AM	Variable
Severity	Severe	Severe	Variable, can be severe
Provoking	Head movement	Lying down Valsalva Head low Exertion	Jaw claudication
Associated Symptoms	Neck stiffness Photophobia Focal deficits (e.g. CN palsies)	N/V Focal neurological symptoms Decreased LOC	Polymyalgia rheumatica Visual loss
Physical Signs	Kernig's sign Brudzinski's sign Meningismus	Focal neurological symptoms Papilledema	Temporal artery changes: firm, nodular, incompressible, tender
Management	CT/MRI with gadolinium, LP, antibiotics for bacterial meningitis	CT/MRI and treatment to reduce pressure See Neurosurgery, NS6 and NS7	Prednisone See Rheumatology, RH22
Etiology	Meningitis, SAH	Tumour, CSVT, IIH, malignant HTN	Vasculitis (GCA)

Migraine

Definition

- ≥5 attacks fulfilling each of the following criteria
  - 4-72 h in duration
  - 2 of the following: unilateral, pulsating, moderate-severe (interferes with daily activity), aggravated by routine physical activity
  - 1 of the following: N/V, photophobia/phonophobia/osmophobia
  - not better accounted for by another diagnosis

Migraine auras can mimic other causes of transient neurological deficits (e.g. TIAs and seizures)

Epidemiology

- 18% females, 6% males; frequency decreases with age (especially at menopause)
- in pre-pubertal children, more commonly seen in males; post-pubertal, more commonly seen in females

"Menstrual Migraine" Subtype
Migraine headache that is associated with the onset of menstruation – usually 2 d before to 3 d after the onset of menstrual bleeding

Etiology and Pathophysiology

- 20% of migraines are associated with aura, caused by depolarizing wave of "cortical spreading depression" across the cerebral cortex (e.g. visual symptoms due to wave through occipital cortex); possible association with vasoconstriction/dilation
- significant genetic contribution
- triggers: stress, sleep excess/deprivation, drugs (estrogen, nitroglycerin), hormonal changes, caffeine withdrawal, chocolate, tyramines (e.g. red wine), nitrites (e.g. processed meats)

Signs and Symptoms

- stages of uncomplicated migraine
  1. prodrome (h to d before headache onset)
  2. aura
  3. headache
  4. postdrome

- aura
  - self-resolving symptom of focal cerebral dysfunction lasting <60 min
  - e.g.: visual disturbance (fortification spectra – zigzags; scintillating scotomata – spots), unilateral paresthesia and numbness or weakness, aphasia
- prodrome/postdrome: appetite change, autonomic symptoms, altered mood, psychomotor agitation/retardation
- classification of migraines
  - common migraine: no aura
  - classic migraine: with aura (headache follows reversible aura within 60 min)
  - complicated migraine: with severe/persistent sensorimotor deficits
  - examples: basilar-type migraine (occipital headache with diplopia, vertigo, ataxia, and altered LOC), hemiplegic/hemisensory migraine, ophthalmoplegic migraine
  - acephalgic migraine (i.e. migraine equivalent): aura without headache
  - status migrainosus: single attack lasting longer than 72 h

Treatment

- avoid triggers
- mild to moderate migraine
  - 1st line: NSAIDs (ibuprofen, naproxen)
- moderate to severe migraine
  - triptans (most effective), ergots (dihydroergotamine, dihydroergotamine mesylate (DHE))
- for chronic migraine, consider migraine prophylaxis: anticonvulsants (valproate, topiramate), TCA (amitriptyline, nortriptyline), propranolol, calcium channel blocker (verapamil)
- medication overuse (use of triptans/opioids/combination analgesics for ≥10 d/mo, or use of NSAIDs for ≥15 d/mo) can lead to medication-overuse headaches

The oral contraceptive pill is contraindicated with complicated migraine due to risk of stroke
- Can still use non-estrogen based forms of birth control (e.g. copper IUD, Depo-provera shot)

If patient presents to ED with severe migraine and N/V – consider treating with IV fluids and anti-emetics (chlorpromazine, prochlorperazine)

Sleep Disorders

Sleep Overview

Recommendations

- newborn: 18 h sleep (50% REM), adolescents: 10 h, adults: 7-9 h but most get insufficient amounts
- many older patients have reduced sleep as a consequence of underlying sleep disorders

Sleep Architecture

- polysomnography measures: EEG, eye movements (electro-oculogram – EOG), EMG, respiratory effort, oxygenation, ECG

Table 25. Sleep Stage Characteristics

	EEG	EOG	Muscle Tone	Other Characteristics
Waking State	Alpha waves: high frequency (8-12 Hz), moderate amplitude Beta waves: frequency >13 Hz, low amplitude	Rapid, blinking	High	
Stage N1 (~5%)	<50% Alpha waves (see above), mixed with slow wave activity (theta, 4-7 Hz)	Slow, roving eye movements	High, but gradually dropping	Marker for very light quality sleep or sleep disruption
Stage N2 (~50%)	K complexes (high voltage negative and positive discharges) with sleep spindles (12-14 Hz) are central and midline	Still	High	
Stage N3 (previously 3 and 4)/Slow Wave/Delta Sleep (~20%)	Delta waves: low frequency (~2 Hz), high voltage (>75 μV)	Still	Low	Homeostatic sleep Reduced BP, HR, cardiac output, RR Growth hormone release
Rapid Eye Movement (REM) (~25%)	Sawtooth waves, mixed frequency, low voltage	Rapid eye movements	Very low	Irregular respiration HR variation Classical dreaming state

Elements of Sleep History
Initiation of sleep
Events prior to bed
Lights
Latency (estimated)
Restless legs
Hallucinations
Maintaining sleep
Number of nighttime awakenings
Sleep walking/talking
Snoring/gasping
Dreams/nightmares
Consequences of sleep
Restorative
Morning headache
Falling asleep in inappropriate setting

Drug Effects on Wakefulness and Sleep

Antihistamines increase sleepiness

Stimulants (e.g. caffeine; an adenosine receptor antagonist) increase arousal and wakefulness

Benzodiazepines reduce amount of slow wave sleep and cause sleepiness

Antidepressants (TCA/MAOI/SSRI) reduce amount of REM sleep and prolong REM latency

EtOH may hasten sleep onset but is associated with increased nighttime arousals and poor sleep efficiency

Avoid sleep medications (especially in elderly patients) due to increased risk of falls, pseudodepression, and memory loss

Coma

- see Neurosurgery, NS40

Insomnia

Definition
- difficulty initiating or maintaining sleep, or waking up earlier than desired (leading to sleep that is chronically non-restorative/poor quality) despite adequate opportunity and circumstances for sleep

Types
- sleep state misperception, psychophysiologic insomnia (learned sleep-preventing associations – i.e. clock watching), idiopathic (lifelong difficulty)
- secondary causes
  - psychiatric disorders (80% of psychiatric patients): i.e. depression and anxiety (see Psychiatry, PS12and PS16)
  - neurologic disorders: i.e. neurodegenerative disease, epilepsy, neuromuscular disorders
  - sleep disorders: i.e. restless legs syndrome (sleep initiation difficulties), sleep apnea (sleep maintenance difficulties)
  - medical conditions: i.e. cardiorespiratory (COPD/heart failure), gastroesophageal reflux disease, pain (arthritis, fibromyalgia, cancer)
  - drugs/toxins: i.e. caffeine, EtOH, stimulants, antidepressants, corticosteroids, sedative withdrawal
  - fatal familial insomnia: i.e. rare genetic prion protein mutation causing autonomic dysfunction
  - pregnancy

Treatment
- sleep log, sleep hygiene, stimulus control, sleep restriction, relaxation response, cognitive behavioural therapy, melatonin

Sleep Apnea

- see Respirology, R29

Definition
- disorder of breathing in sleep associated with sleep disruption and consequent excessive somnolence (or drowsiness)

Epidemiology
- >6% of the Canadian population
- risk factors and associated conditions: older age, obesity, male sex, craniofacial and upper airway abnormalities
- significant morbidity: HTN, stroke, heart failure, sleepiness, mortality (accidents)

Types
- obstructive sleep apnea; etiology: collapse of airway due to low muscle tone in deep and REM sleep
- central sleep apnea: no effort to breath >10s; etiology: heart failure, opiates, brainstem pathology, myotonic dystrophy
- mixed apnea: combination of both central and obstructive sleep apnea

Diagnosis
- PSGs: home sleep apnea testing, in-hospital testing
  - apnea-hypopnea index (AHI) ≥5

Treatment
- continuous positive airway pressure (CPAP), weight loss, positional therapy (e.g. avoidance of supine sleep), dental devices, surgery (rare), ensure driving safety

Restless Legs Syndrome

- urge to move legs accompanied by uncomfortable sensations that begin or worsen with rest, is partially or totally relieved with movement, and is worse in evening/night
- 90% also have periodic limb movement disorder
- associated with iron deficiency, neuropathy, PD, EtOH, pregnancy, end-stage renal disease

Treatment
- iron supplementation if iron deficient
- gabapentinoids (pregabalin, gabapentin)
- dopamine agonists (pramipexole, rotigotine)
- benzodiazepines (usually clonazepam)
- opioids, if medically refractory

Periodic Limb Movement Disorder

- involuntary, jerking movements of the legs during sleep
- diagnosed with polysomnography
- 50% also have restless legs syndrome
- similar associated factors and treatment as restless legs syndrome

Narcolepsy

Definition
- excessive daytime sleepiness (all narcolepsy), cataplexy (loss of muscle tone with emotional stimuli, pathognomonic), sleep paralysis (unable to move upon wakening), hypnagogic and hypnopompic hallucinations (vivid hallucinations while falling asleep or waking up, respectively)

Epidemiology
- prevalence 1 in 2000, onset in adolescence/early adulthood; life-long disorder

Etiology
- presumed autoimmune attack on orexin/hypocretin system, post head injury, MS, hypothalamic tumours; rarely familial

Diagnosis
- based on clinical history and multiple sleep latency test findings of short sleep latency <8 min and REM within 15 min of sleep onset on 2/4 naps

Treatment
- sleep hygiene and scheduled brief naps, restricted driving
- alerting agents: modafinil (non-amphetamine stimulant), stimulant (i.e. methylphenidate)
- anticataplectic: TCAs, SSRIs, sodium oxybate

Parasomnias

Definition
- unusual behaviours in sleep with clinical features appropriate to stage of sleep

Etiology
- in elderly, REM sleep behaviour disorder may be associated with PD; in children, slow wave sleep arousals (sleep walking) may be associated with sleep-disordered breathing

Diagnosis
- clinical history in children, PSG in adults to exclude nocturnal seizures

Treatment
- behavioural management (safety, adequate sleep), clonazepam for REM sleep behaviour, tonsillectomy if appropriate in children

Central Nervous System Infections

- see Infectious Diseases, ID17

Spinal Cord Syndromes

- see Neurosurgery, NS34

Stroke

Terminology

- stroke: focal cerebral, spinal, or retinal infarction in a defined vascular distribution
  - infarction is permanent tissue injury (confirmed by neuroimaging)
- TIA: transient (<24 h), episode of neurological dysfunction caused by focal brain, spinal cord, or retinal ischemia without acute infarction on CT or MRI
  - may present with amaurosis fugax (transient monocular painless vision loss)

Pathophysiology

- two major types: ischemic (~80%) and hemorrhagic (~20%)

1. ischemic

- arterial thrombosis: thrombus formation in artery (local/in situ)
  - large vessel: stenosis or occlusion of the internal carotid artery, vertebral artery, basilar artery, or anterior/middle/posterior cerebral arteries
    - mechanism: insufficient blood flow beyond lesion (hemodynamic stroke)
    - underlying processes: atherosclerosis (most common cause), dissection, and vasculitis
  - small vessel/lacunar
    - mechanism: chronic HTN and DM cause vessel wall thickening and decreased luminal diameter
    - affects mainly small penetrating arteries (primarily basal ganglia, internal capsule, and thalamus)
- cardioembolic: blockage of cerebral arterial blood flow due to thrombus originating from a cardiac source
  - atrial fibrillation (most common), rheumatic valve disease, prosthetic heart valves, recent MI, fibrous and infectious endocarditis
- systemic hypoperfusion (global cerebral ischemia)
  - inadequate blood flow to brain, usually secondary to cardiac pump failure (e.g. cardiac arrest, arrhythmia, or MI)
  - primarily affects watershed areas (between the major cerebral arterial territories)

2. hemorrhagic

- intracerebral hemorrhage: bleeding into brain parenchyma
  - hypertensive (most common): due to chronic arteriosclerosis which predisposes vessels to focal necrosis and pseudoaneurysm formation eventually leading to intraparenchymal hemorrhage; most common sites are putamen, caudate nucleus, thalamus, cerebellum, and pons
  - other: trauma, amyloid angiopathy (associated with lobar hemorrhage), vascular malformations, aneurysms, vasculitis, drug use (cocaine or amphetamines)
- SAH, see Neurosurgery, NS22

Stroke Syndromes According to Vascular Territory

- anterior cerebral artery
  - contralateral leg weakness and/or sensory deficit
  - neurocognitive deficits (e.g. abulia, agitation, emotional lability)
- middle cerebral artery: most common artery involved in ischemic stroke
  - contralateral weakness and/or sensory deficit of face and arm
  - cortical sensory loss
  - may have contralateral homonymous hemianopsia or quadrantanopsia
  - if dominant (usually left) hemisphere: aphasia
  - if non-dominant (usually right) hemisphere: neglect, anosognosia
  - eye deviation towards the side of the lesion (away from the weak side)

Hypertensive Encephalopathy
Acute severe HTN (typically dBP >130 or sBP >200) can cause hypertensive encephalopathy. Abnormal fundoscopic exam (papilledema, hemorrhages, exudates, cotton-wool spots), focal neurologic symptoms, N/V, visual disturbances, seizures, and change in LOC

Consider transfer of acute stroke patient to a designated stroke centre for neuroprotective or thrombolytic therapy, and endovascular therapy if the patient is seen in first few hours

Early seizure activity occurs in 5-25% of patients after ICH

Cerebral venous sinus thrombosis should be considered in the differential diagnosis of stroke and headache. It is an uncommon cause of either, but is associated with high morbidity and mortality. Patients often present with headache alone, but can have seizures, focal neurological deficits, or cranial nerve palsies. This is diagnosed with CT venography or magnetic resonance venography. Treatment is typically anticoagulation with heparin initially, then warfarin eventually

20-40% of patients with ischemic stroke may develop hemorrhagic transformation within 1 wk after the initial infarction
Can be exacerbated by reperfusion injury (distal migration of clot as it dissolves) naturally or by use of thrombolytic therapy, endovascular thrombectomy, or anticoagulation

Blood work should only delay treatment if patient is on anticoagulants, low platelet count suspected, abnormal electrolytes suspected, or any bleeding abnormality suspected

Suspect an alternate diagnosis if fever, decreased LOC, fluctuating symptoms, gradual onset, no focal neurological symptoms, and/or positive symptoms

Infarcted area of brain tissue can often appear normal on CT during the first several hours after stroke onset, especially if in posterior circulation

- posterior cerebral artery
  - contralateral homonymous hemianopsia or quadrantanopsia
  - midbrain findings: CN III and IV palsy/pupillary changes, hemiparesis
  - thalamic findings: sensory loss, amnesia, decreased LOC
  - if bilateral: cortical blindness or prosopagnosia
  - hemiballism
- basilar artery
  - proximal (usually thrombosis): impaired eye movements, vertical nystagmus, reactive miosis, hemi- or quadriplegia, dysarthria, ataxia, locked-in syndrome, coma
  - distal (usually embolic, i.e. top of the basilar syndrome): somnolence, memory and behaviour abnormalities, oculomotor deficit
- posterior inferior cerebellar artery (lateral medullary or Wallenberg syndrome)
  - ipsilateral ataxia, ipsilateral Horner's syndrome, ipsilateral facial sensory loss, contralateral limb impairment of pain and temperature sensation, nystagmus, vertigo, N/V, dysphagia, dysarthria, hiccups
- medial medullary infarct (anterior spinal artery, which can be associated with anterior cord infarct)
  - contralateral hemiparesis (facial sparing), contralateral impaired proprioception and vibration sensation, ipsilateral tongue weakness
- lacunar infarcts (deep hemispheric white matter; involving deep penetrating arteries of middle cerebral artery, circle of Willis, basilar and vertebral arteries)
  - contralateral face, arm, leg hemiparesis
- common lacunar syndromes:
  - sensorimotor stroke: weakness and numbness of the face/arm/leg without other cortical signs (i.e. aphasia, apraxia, visual loss)
  - pure motor hemiparesis (posterior limb of internal capsule or ventral pons): contralateral arm, leg, and face
  - pure sensory loss (ventral thalamic): hemisensory loss
  - ataxic hemiparesis (ventral pons or internal capsule): ipsilateral ataxia and leg paresis
  - dysarthria-clumsy hand syndrome (ventral pons or genu of internal capsule): dysarthria, facial weakness, dysphagia, mild hand weakness, and clumsiness

Figure 26. Vascular territories

See Landmark Neurology Trials for more information on the ARISTOTLE trial. It details the efficacy of apixaban, an oral direct factor Xa inhibitor, in reducing the risk of stroke, as compared to warfarin.

The National Institute of Health Stroke Scale (NIHSS) is a standardized clinical examination that determines the severity of an acute stroke; it can also be used to monitor response to treatment over time

The scale uses 11 items that evaluate:

- LOC
- Visual system
- Motor system
- Sensory system
- Language abilities

Scoring (x/42):
0=no stroke
1-4=mild stroke
5-15=moderate stroke
16-20=moderate to severe stroke
21-42=severe stroke

ASPECTS: 10-Point Quantitative Score to Assess Ischemic Changes on CT

10/10 is normal and <4/10 signifies high-risk of bleed with tPA

Subtract 1 point for each of the following structures if abnormal within the ischemic hemisphere: caudate, lentiform, insula, internal capsule, middle cerebral artery 1, 2, 3, 4, 5, 6 regions

If tPA is given at stroke onset, delay acute antiplatelet/anticoagulation treatment by 24 h

Absolute Contraindications to tPA
Any source of active hemorrhage, any hemorrhage on brain imaging, any condition that could increase the risk of major hemorrhage after tPA administration

Assessment of Acute Ischemic Stroke

General Assessment

- ABCs, full vital sign monitoring, capillary glucose (Accu-Chek®), urgent CODE STROKE if <4.5 h from symptom onset (for possible thrombolysis), NIHSS
- LOC (knows age, month; obeys commands), dysarthria, dysnomia (cannot name objects)
- gaze preference, visual fields, facial palsy
- arm drift, leg weakness, ataxia
- sensation to pinprick, extinction/neglect
- history
  - onset: time when last known to be awake and symptom free
  - mimics to rule out: seizure/post-ictal, hypoglycemia, migraine, conversion disorder
- investigations
  - neuroimaging: non-contrast CT head (STAT) to rule out hemorrhage, MRI
  - vascular imaging: CT angiography (STAT), carotid Doppler ultrasound, magnetic resonance angiography, ECG
  - ECG, Holter monitor, transthoracic echocardiogram: to rule out cardioembolic causes such as atrial fibrillation
  - CBC, electrolytes, creatinine, partial thromboplastin time (PTT)/INR, blood glucose, lipid profile
- imaging (i.e. CT ± MR or CT angiography) signs of stroke
  - loss of cortical white-grey differentiation
  - sulcal effacement (i.e. mass effect decreases visualization of sulci)
  - hypodensity of parenchyma
  - insular ribbon sign
  - hyperdense middle cerebral artery sign
  - calculate ASPECTS score for CT

Treatment of Acute Ischemic Stroke

1. Neuroprotective Strategies

- BP, glucose, temperature control (exact targets will depend on clinical scenario)

2. Intravenous Thrombolysis

- tPA should be given within 4.5 h of acute ischemic stroke onset provided there are clinical indications and no contraindications to use (see sidebar)

3. Mechanical Thrombectomy

- early endovascular treatment of proximal anterior circulation occlusion has significant benefit on outcomes
  - ≤6 hr: with small-to-moderate ischemic core on CT
  - 6-24 hr: CT perfusion used to select patients who meet DAWN trial criteria
  - for basilar occlusions: weigh risks and benefits
- current standard of care is IV tPA + mechanical thrombectomy

4. Antiplatelet Therapy

- loading dose of antiplatelets at presentation of TIA or stroke if tPA not received (acute therapy)
  - loading dose of ASA: recommended dose 160 mg chewed
  - if patient intolerant to ASA, use another antiplatelet agent (e.g. clopidogrel 300 mg)
- secondary stroke prevention
  - if high risk TIA or minor stroke (NIHSS ≤4), load with ASA and clopidogrel and treat with dual antiplatelet therapy for 21 d (ASA 81 mg and clopidogrel 75 mg), followed by antiplatelet monotherapy

5. Acute Anticoagulant Therapy

- delay initiation/hold oral anticoagulation depending on size of infarct and presence of petechial/frank hemorrhage

Other Acute Management Issues

- avoid hyperglycemia which can increase the infarct size
- lower temperature if febrile (febrile stroke: think septic emboli from endocarditis)
- prevent complications
  - NPO if dysphagia (to be reassessed by SLP)
  - DVT prophylaxis if bed-bound
  - initiate rehabilitation early

Relative Contraindications to rtPA
Historical: history of ICH, stroke, or serious head/spinal trauma in the preceding 3 mo, major surgery in the preceding 14 d (risk varies by procedure), arterial puncture at a non-compressible site in the previous 7 d
Clinical: suspicious for SAH, suspicious for another non-ischemic acute neurological condition (e.g. post-ictal Todd's paralysis, focal neurological signs due to severe hypo- or hyperglycemia), elevated BP (sBP ≥180 mmHg, dBP ≥105 mmHg) refractory to treatment, current use of direct oral anticoagulant
Imaging: early signs of extensive infarction
Laboratory: ood glucose <2.7 mmol/L or >22.2 mmol/L, elevated activated partial thromboplastin time (aPTT), INR >1.7, platelet count <100 x 10^{3}mm^3

See Landmark Neurology Trials for more information on the DAWN trial. It details the efficacy and safety of endovascular thrombectomy performed more than 6 h after the onset of ischemic stroke in patients who were well 6-24 h earlier with a mismatch between clinical deficit and infarct.

See Landmark Neurology Trials for more information on the SPARCL trial. It details whether statins reduce the risk of stroke after a recent stroke or TIA.

Evaluating for Occult Atrial Fibrillation – CRYSTAL AF Trial
NEJM 2014:370;2478-86
Purpose: To investigate optimal methods for using ECG to detect atrial fibrillation after cryptogenic stroke.
Methods: 441 patients ≥40 yr with no evidence of atrial fibrillation during ≥24 h ECG monitoring received long-term monitoring with an insertable cardiac monitor (ICM) or conventional follow-up (control).
Results: Incidence of atrial fibrillation detection in the ICM group vs. the control group was 8.9% vs. 1.4% at 6 mo (hazard ratio, 6.4; 95% CI, 1.9-21.7; P<0.001), and 12.4% vs. 2.0% at 12 mo (7.3 (2.6-20.8); P<0.001), respectively.
Conclusion: Following cryptogenic stroke, ECG monitoring with ICM was more effective than conventional follow-up for detecting atrial fibrillation.

Carotid endarterectomy needs to be done within 2 wk of the ischemic event for the most benefit

Blood Pressure Control
- do not lower the blood pressure unless the HTN is severe
- antihypertensive therapy is withheld for 48-72 h (permissive hypertension) after non-thrombolysed ischemic stroke unless sBP >220 mmHg or dBP >120 mmHg, or in the setting of acute MI, renal failure, aortic dissection (IV labetalol first-line if needed)
  - if patient receives tPA, target BP ≤180/105 mmHg
- acutely elevated BP is necessary to maintain brain perfusion to the ischemic penumbra
- most patients with an acute cerebral infarct are initially hypertensive but their BP will improve within 1-2 d

Stroke Rehabilitation
- individualized based on severity and nature of impairment; may require inpatient program and continuation through home care or outpatient services
- multidisciplinary approach includes dysphagia assessment and dietary modifications, communication rehabilitation, cognitive and psychological assessments including screen for depression, therapeutic exercise programs, assessment of ambulation and evaluation of need for assistive devices, splints or braces, vocational rehabilitation

Primary and Secondary Prevention of Ischemic Stroke

Antiplatelet Therapy
- primary prevention
  - no firm evidence of a protective role for antiplatelet agents in low-risk patients without a prior stroke/TIA
- secondary prevention
  - initial choice: ASA, but other antiplatelet agents reasonable alternatives (clopidogrel or ASA/dipyridamole)
  - longer-term use of combined ASA and clopidogrel not recommended for secondary prevention unless there is an alternate indication (e.g. coronary drug-eluting stent requiring dual antiplatelet therapy), due to increased risk of bleeding and mortality

Carotid Stenosis
- primary prevention (asymptomatic)
- carotid endarterectomy is controversial: if stenosis >60%, risk of stroke is 2% per yr; carotid endarterectomy reduces the risk of stroke by 1% per yr (but 5% risk of complications)
- secondary prevention (previous stroke/TIA in carotid territory)
  - carotid endarterectomy clearly benefits those with symptomatic severe stenosis (70-99%), as well as those with moderate stenosis (50-69%) but to a lesser degree (NASCET trial), see Vascular Surgery, VS9
- according to the CREST trial, endarterectomy and carotid stenting have similar benefits in a composite endpoint of reduction of stroke, MI, and death; however, in the periprocedural period, stenting results in a higher rate of stroke, while endarterectomy results in a higher rate of MI

Atrial Fibrillation
- primary and secondary prevention with anticoagulation
  - classical risk stratification used CHADS2 score (0-6), but Stroke 2014 guidelines recommend that virtually all patients with atrial fibrillation without contraindication be anticoagulated
    - 0 (low-risk, 1.9% annual stroke risk): antiplatelet
    - 1 (intermediate risk, 2.8% annual stroke risk): anticoagulant or antiplatelet – patient specific decision
    - >2 (high-risk, 4-18.2% annual stroke risk): anticoagulant
  - anticoagulation therapy
    - warfarin (titrate to INR 2-3)
    - direct oral anticoagulants (DOAC): dabigatran (110 or 150 mg PO BID), apixaban (2.5 or 5 mg PO BID), rivaroxaban (15 or 20 mg PO once daily), or edoxaban (30 or 60 mg once daily) may be alternatives to warfarin and generally have a lower risk of ICH
- Praxbind® reversal agent for dabigatran if necessary
- Andexanet® reversal agent for apixaban and rivaroxaban if necessary
- do not use DOAC in patients with mechanical heart valves or AF with valvular heart disease

Hypertension
- primary prevention
  - targets: BP <140/90 mmHg (sBP <120 mmHg for high-risk without DM (SPRINT trial) or <130/80 mmHg for people with DM or renal disease)
  - ACE inhibitor: ramipril 10 mg PO once daily is effective in patients at high-risk for cardiovascular disease (HOPE trial)
- secondary prevention
  - combination of ACE inhibitor and thiazide diuretics are recommended in patients with previous stroke/TIA (PROGRESS trial)

CHADS2
Stroke risk stratification for patients with atrial fibrillation
CHF (1 point)
HTN sBP >160 mmHg/treated HTN (1 point)
Age >75 yr (1 point)
DM (1 point)
Prior Stroke or TIA (2 points)

ABCD^2 Score
To predict/identify individuals at high-risk of stroke following TIA
Age: 1 point for age >60 yr
Blood pressure (at presentation): 1 point for HTN (>140/90 mmHg at initial evaluation)
Clinical features: 2 points for unilateral weakness, 1 point for speech disturbance without weakness
Duration of symptoms: 1 point for 10-59 min, 2 points for >60 min
DM: 1 point
Stroke risk: 0-3: low-risk, 4-5: moderate risk, 6-7: high-risk

See Landmark Neurology Trials for more information on the SAMMPRIS trial. It compares the efficacy of percutaneous transluminal angioplasty and stenting (PTAS) to aggressive medical management in intracranial arterial stenosis.

Endovascular Thrombectomy after Large-Vessel Ischemic Stroke: A Meta-Analysis of Individual Patient Data from Five Randomized Trials
Lancet 2016;387:1723-1731
Purpose: To compare the efficacy of endovascular thrombectomy to standard medical care in patients with acute ischemic stroke due to occlusion of the proximal anterior circulation.
Study: A meta-analysis of individual patient data from 5 RCTs (MR CLEAN, ESCAPE, REVASCAT, SWIFT PRIME, and EXTEND IA).
Results: Data from 1287 individual patients (634 assigned to endovascular thrombectomy and 653 assigned to control) were analyzed. The number needed to treat to reduce disability for one patient by at least one level on the modified Rankin Scale, which measures disability and dependence in activities of daily living, was 2.6. Mortality at 90 d and risk of parenchymal hematoma and symptomatic ICH did not differ between the endovascular thrombectomy and control groups.
Conclusion: Most patients—irrespective of patient characteristics or geographical location—with acute ischemic stroke caused by occlusion of the proximal anterior circulation benefit from endovascular thrombectomy.

Hypercholesterolemia
- primary prevention
  - statins in patients with CAD or at high-risk for cardiovascular events, even with normal cholesterol (CARE trial)
- secondary prevention
  - target LDL <2 mmol/L (or 50% reduction in LDL); high dose atorvastatin (SPARCL trial) but lower doses may be adequate if intolerable

Type 1 and Type 2 Diabetes
- HbA1c <7%, fasting blood glucose 4-7 mmol/L, 2 h postprandial plasma glucose target 5-10 mmol/L

Smoking
- primary prevention: smoking increases risk of stroke in a dose-dependent manner
- secondary prevention: combination of pharmacological therapy and behavioural therapy should be considered in all smoking cessation programs; after smoking cessation, the risk of stroke decreases to baseline within 2-5 yr

Physical Activity
- beneficial effect of regular physical activity has a dose-related response in terms of intensity and duration of activity

Intracranial Hemorrhage

Definition
- intracranial bleeding into epidural space (epidural hematoma), subdural space (subdural hematoma), subarachnoid space (SAH), brain parenchyma (ICH), or ventricles (intraventricular hemorrhage)

Etiology
- head trauma, aneurysm, arteriovenous malformation, cavernous malformation, brain tumour, hemorrhagic stroke

Investigations
- general investigations: see *Assessment and Treatment of Acute Ischemic Stroke, N53*
- further investigations, when clinically indicated:
  - LP (if CT head negative and >6 h from headache onset)
  - may require cerebral angiogram if suspecting aneurysm or arteriovenous malformation
  - if typical location for hypertensive hemorrhage, repeat CT head in 4-6 wk after hemorrhage has resolved to rule out an underlying lesion

Treatment
- medical
  - anti-hypertensives: no conclusive BP target ranges for managing ICH exist; 2020 Canadian Stroke Best Practice Guidelines suggest that sBP<140-160 mmHg for the first 24-48h post-ICH is reasonable
  - ICP lowering medical management (if necessary): see Neurosurgery, NS8
- surgical: see Neurosurgery, NS8

Neurocutaneous Syndromes
- see Pediatrics, P89

Multiple Sclerosis

Definition
- an autoimmune chronic inflammatory disease of the CNS characterized by relapsing-remitting or progressive neurologic symptoms due to inflammation, demyelination, and axonal degeneration

Epidemiology
- global prevalence ~2.8 million
- onset 17-35 yr; F:M=3:1
- genetic
  - polygenetic: the HLA-DRB1 gene has been demonstrated to be a genetically susceptible area
  - 30% concordance for monozygotic twins, 2-4% risk in offspring of affected mother or father
- environmental
  - MS is more common in regions with less sun exposure and lower stores of vitamin D (Europe, Canada, US, New Zealand, Southeast Australia)
  - MS has also been linked to certain viruses (e.g. EBV)

ACE Inhibitor in Stroke Prevention – HOPE Trial
NEJM 2000;342:145-153
Study: Randomized, blinded, placebo-controlled trial. Mean follow-up 5 yr.
Patients: 9297 patients ≥55 yr (mean age 66 yr, 73% men) who had evidence of vascular disease or DM plus one other cardiovascular risk factor and who were not known to have a low ejection fraction or heart failure.
Intervention: Ramipril 10 mg PO once daily vs. matching placebo.
Main Outcomes: Stroke, MI, or death from cardiovascular causes.
Results:

Outcome	RRR (95%CI)	NNT (CI)
Stroke	32% (16-44)	67 (43-145)
MI, stroke, or CV mortality	26 (19-43)	22% (14-30)
All-cause mortality	16% (5-25)	56 (32-195)

Treatment with ramipril reduced the risk of stroke (3.4% vs. 4.9%; RR 0.68; P<0.001).
Conclusions: In adults at high-risk for cardiovascular events, ramipril reduced the risk of stroke, as well as other vascular events and overall mortality. In addition, ACEI reduce risk of stroke beyond their hypertensive effect.

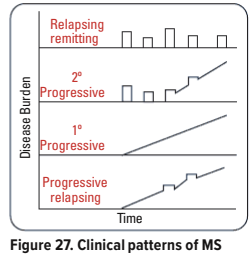

Figure 27. Clinical patterns of MS

Most symptoms in MS are due to cord, brainstem, and optic nerve lesions

Chronic Cerebrospinal Venous Insufficiency (CCSVI)
A theory proposed in 2008 described abnormal venous blood flow in patients with MS; while some RCTs are still underway, recent studies have largely discredited this highly controversial theory. That is, studies indicate no connection between CCSVI and MS

Clinical Patterns
- clinically isolated syndrome (CIS): first clinical episode that is suggestive of MS
- relapsing-remitting (RRMS) 85%, primary progressive (PPMS) 10%, progressive relapsing (PRMS) 5%, secondary progressive (SPMS)
- most RRMS goes on to become SPMS

Clinical Features
- an MS exacerbation is characterized by the onset of new neurological symptoms lasting more than 24 h, in the absence of fever or infection
  - symptoms typically peak over days to weeks, followed by variable improvement over weeks to months
  - in RRMS, average 0.4-0.6 relapses per yr, but higher disease activity in first yr of disease
- symptoms include numbness, visual disturbance (optic neuritis), weakness, spasticity, diplopia (e.g. internuclear ophthalmoplegia), impaired gait, vertigo, bladder dysfunction, executive function impairment
- Lhermitte's sign: flexion of neck causes electric shock sensation down back into limbs suggestive of a dorsal cervical cord lesion
- Uhthoff's phenomenon: worsening of symptoms in heat
- SPMS: classically presents with progressive weakness and gait dysfunction with cerebellar findings of arms (i.e. intention tremor); associated features: fatigue, depression, subtle cognitive dysfunction, autonomic dysfunction

Diagnosis
- demonstration of both dissemination in time and space based on the revised McDonald criteria (2017)
  - dissemination in time: ≥2 attacks (lasting at least 24 h with 30 d between the 2 attacks), simultaneous presence of gadolinium enhancing and non-enhancing MRI lesions at any time, or a new T2 and/or gadolinium-enhancing lesion(s) on follow-up MRI, presence of CSF oligoclonal bands
  - dissemination in space: ≥1 T2 lesions on MRI in at least 2 of the 4 CNS regions (periventricular, cortical/juxtacortical, infratentorial, or spinal cord) or developing a second attack that implicates a different CNS region

MS Variants
- Devic's = neuromyelitis optica (NMO): severe optic neuritis and longitudinally extensive transverse myelitis extending >3 vertebral segments (aquaporin-4 antibody positive)
- tumefactive MS: solitary lesion >2 cm mimicking neoplasms on MRI
- fulminant MS (Marburg): rapidly progressive and fatal MS associated with severe axonal damage, inflammation, and necrosis
- pediatric MS: onset of MS before the age of 18
  - epidemiology: rare (1.35-2.5 in 100000 children)
  - presentation: more likely to present with isolated optic neuritis, isolated brainstem syndrome, or symptoms of encephalopathy compared to adults
  - course: 98% have RRMS
  - diagnosis and treatment similar to adult MS
  - differential diagnosis: in the setting of nonspecific CSF abnormalities and MRI evidence of white matter lesion, rule out acute disseminated encephalomyelitis (ADEM), optic neuritis, transverse myelitis, neuromyelitis optica, CNS malignancies, stroke, leukodystrophies, and mitochondrial disease
- ADEM: monophasic demyelinating disorder with multifocal neurologic symptoms with encephalopathy seen mainly in children, often following infection

Investigations
- MRI: demyelinating plaques appear as hyperintense lesions on T2-weighted MRI, with active lesions sometimes showing enhancement with gadolinium
  - typical locations: periventricular, corpus callosum, cerebellar peduncles, brainstem, juxtacortical region, and dorsolateral spinal cord
  - Dawson's fingers: periventricular lesions extending into corpus callosum
  - T1 "black holes"
  - cranial MRI is more sensitive than spinal MRI
- CSF: oligoclonal bands in 90%, increased IgG concentration
- evoked potentials (visual/auditory/somatosensory): delayed but well-preserved wave forms

Treatment
- acute exacerbation treatment: methylprednisolone 1000 mg IV daily x 3-7 d (no taper required) or prednisone 1000-1250 mg PO daily x 3-7 d (no taper required); if poor response to corticosteroids, may consider plasma exchange
- long-term treatment: vitamin D 4000 units daily
- disease modifying therapy (DMT)
  - goals: decrease relapse rate, decrease progression of disability, slow accumulation of MRI lesions
  - first line: teriflunomide, interferon-β (injection: Betaseron®, Avonex®, Rebif®), glatiramer acetate (injection: Copaxone®), dimethyl fumarate (Tecfidera®)
  - second line: natalizumab (Tysabri®) (monthly IV infusion), fingolimod (Gilenya®), ocrelizumab (Ocrevus®), alemtuzumab (Lemtrada®), cladribine (Mavenclad®), ofatumumab (Kesimpta®)
  - increased risk of progressive multifocal leukoencephalopathy associated with natalizumab; also described with fingolimod, dimethyl fumarate, and ocrelizumab, but to a lesser degree

The Expanded Disability Status Scale (EDSS) is used as a measure of disability progression and is scored from 0 to 10 based on the neurologic exam and ambulation

Fingolimod for Relapsing-Remitting Multiple Sclerosis
Cochrane DB Syst Rev 2016;4:CD009371
Purpose: Systematic literature review of the evidence for fingolimod in treatment of relapsing-remitting MS.
Study: Meta-analysis of six RCTs (n=55152) investigating the benefits and harms of fingolimod and other disease modifying drugs in the treatment of relapsing-remitting MS.
Results: Compared to placebo and interferon β-1a, fingolimod increases the probability of being relapse free at 24 mo (RR 1.44 vs. placebo, RR 1.18 vs. interferon β-1a) but has little to no effect on disability progression (RR 1.07 vs. placebo, RR 1.02 vs. interferon β-1a). Fingolimod use was associated with a higher incidence of adverse events and discontinuation within 6 mo.
Conclusions: Fingolimod significantly reduces disease activity in relapse-remitting MS compared to placebo but does not prevent disability. Its use is associated with adverse events and requires close patient monitoring, particularly within the first 6 mo. Further study is needed to assess the benefits of fingolimod vs. other disease modifying drugs.

Recombinant Interferon β or Glatiramer Acetate for Delaying Conversion of the First Demyelinating Event to Multiple Sclerosis
Cochrane DB Syst Rev 2008;2:CD005278
Study: Meta-analysis of RCTs investigating clinically isolated syndrome (CIS) pateints treated with immunomodulatory drugs.
Primary Outcomes: Proportion of patients converting to clinically definite MS and adverse effects.
Results: Three trials (n=1160) tested the efficacy of interferon beta (IFN) and no trial tested glatiramer acetate (GA). The pooled odds ratio (OR) for patients on IFN vs. placebo at 1 yr was 0.53 (95% CI 0.40-0.71, P<0.0001). The 2 yr follow-up OR was 0.52 (95% CI 0.38-0.70, P<0.0001). There was no significant increase in adverse events for those on IFN.
Conclusions: IFN treatment can delay progression to clinically definite MS in patients with CIS over 2 yr.

See Landmark Neurology Trials for more information on the PreCISe trial. It details the efficacy of early treatment with glatiramer acetate in delaying onset of clinically definite multiple sclerosis (MS).

  - CIS: early treatment may delay potential second attack; glatiramer acetate, interferons, and teriflunomide all with RCT data
  - RRMS: first-line DMT reduces rate of relapse by about 30%; second-line by 50-90%
  - PPMS: ocrelizumab infusion (ORATORIO trial 2017)
  - SPMS: siponimod (Mayzent®)
- symptomatic treatment
  - spasticity: baclofen, tizanidine, dantrolene, benzodiazepine, botulinum toxin
  - bladder dysfunction: oxybutynin, mirabegron
  - pain: TCA, carbamazepine, gabapentin
  - fatigue: amantadine, modafinil, methylphenidate
  - depression: psychotherapy, antidepressants, lithium
  - constipation: high fibre intake, stool softener, laxatives
  - sexual dysfunction: sildenafil (Viagra®), tadalafil (Cialis®), vardenafil (Levitra®, Staxyn®)
- education and counselling: MS Society, support groups, psychosocial issues

Prognosis

- good prognostic indicators: female, age <40 at onset, RRMS, presenting with optic neuritis, low burden of disease on initial MRI, low rate of relapse early in disease, good recovery between exacerbations
- PPMS: poor prognosis, higher rates of disability, poor response to therapy

Common Medications

Table 26. Common Medications for Neurological Disorders

Indications	Mechanism of Action/Class	Generic Name	Trade Name	Dosing	Contraindications	Side Effects
Parkinson's Disease	Dopamine precursor	levodopa + carbidopa	Sinemet®	Carbidopa 25 mg/levodopa 100 mg PO TID Maximum 200 mg carbidopa and 2000 mg levodopa/d	Use of MAO inhibitor in last 14 d	Nausea, hypotension, hallucinations, dyskinesias
	Dopamine agonist	pramipexole ropinirole rotigotine	Mirpaex® Requip® Neupro®	Initial: 0.125 mg TID Maximum: 4.5 mg/d Initial: 0.25 mg TID Maximum: 8 mg	Hypersensitivity	Hallucinations, nausea, dizziness, headache, insomnia, somnolence, application site reactions (rotigotine)
	MAOB inhibitor	rasagiline selegiline safinamide	Azilect® Eldepryl®	5 mg PO BID 1 mg PO once daily	Concomitant use of meperidine or tricyclic antidepressants	Headache, insomnia, dizziness, nausea, dry mouth, hallucinations, confusion, orthostatic hypotension, increased akinesia, risk of hypertensive crisis with tyramine-containing foods
Myasthenia Gravis	Acetylcholinesterase inhibitor	pyridostigmine	Mestinon®	600 mg/d PO divided in 5-6 doses Range 60-1500 mg/d	GI or GU obstruction	N/V, diarrhea, abdominal cramps, increased peristalsis, increased salivation, increased bronchial secretions, miosis, diaphoresis, muscle cramps, fasciculations, muscle weakness, bradycardia
Acute Migraine	Triptan (selective 5-hydroxytryptamine receptor agonist)	sumatriptan	Imitrex®	25-100 mg PO PRN, maximum 200 mg/d	Hemiplegic/basilar migraine, ischemic heart disease, CVD, uncontrolled HTN, use of ergotamine/5-HT1 agonist in past 24 h, use of MAO inhibitor in last 14 d, severe hepatic disease	Vertigo, chest pain, flushing, sensation of heat, hypertensive crisis, peripheral vascular disease, coronary artery vasospasm, cardiac arrest, nausea, vomiting, headache, hyposalivation, fatigue
	Ergot (5-HT1D receptor agonist)	dihydroergotamine	Migranal®	Nasal spray 0.5 mg/spray, maximum 4 sprays/d	Hemiplegic/basilar migraine, high-dose ASA therapy, uncontrolled HTN, ischemic heart disease, peripheral vascular disease, severe hepatic or renal dysfunction, use of triptans in last 24 h, use of MAO inhibitors in last 14 d	Coronary artery vasospasm, transient myocardial ischemia, MI, ventricular tachycardia, ventricular fibrillation; may cause significant rebound headache
Migraine Prophylaxis	Anticonvulsant	topiramate	Topamax®	25 mg PO (in evening); may increase weekly by 25 mg/d to a max 50 mg BID	Nephrolithiasis	Sedation, mood disturbance, cognitive dysfunction, anorexia, nausea, diarrhea, paresthesias, metabolic acidosis, glaucoma, Stevens-Johnson syndrome, toxic epidermal necroylysis
	β-blocker	propranolol	Inderal®	80 mg/d divided every 6-8 h; increase by 20-40 mg/dose every 3-4 wk to max 160-240 mg/d in divided doses q6-8 h	Uncompensated CHF, severe bradycardia or heart block, severe COPD or asthma	Fatigue, cognitive dysfunction, disturbed sleep, rashes, dyspepsia, dry eyes, heart failure, bronchospasm, risk of acute tachycardia and HTN if withdrawal

SJS: Stevens-Johnson Syndrome, TES: toxic epidermal necrolysis

Table 26. Common Medications for Neurological Disorders

Indications	Mechanism of Action/Class	Generic Name	Trade Name	Dosing	Contraindications	Side Effects
Epilepsy	Anticonvulsant for partial ± 2° generalization, generalized tonic-clonic	carbamazepine	Tegretol®	Start at 100-200 mg PO once daily to TID, increase by 200 mg/d up to 800-1200 mg/d	History of bone marrow depression, hepatic disease, hypersensitivity to the drug, use of MAO inhibitor in last 14 d	Drowsiness, headache, unsteadiness, dizziness, N/V, skin rash, agranulocytosis/aplastic anemia (rare)
	Anticonvulsant for partial, tonic-clonic, status epilepticus	phenytoin	Dilantin®	100 mg PO TID, maintenance dose up to 200 mg PO TID SE: 10-15 mg/kg IV loading dose then maintenance doses of 100 mg PO or IV q6-8 h	Hypersensitivity, pregnancy, breastfeeding; caution with P-450 interactions	Hypotension, Stevens-Johnson syndrome, toxic epidermal necroylysis, SLE-type symptoms, gingival hypertrophy, peripheral neuropathy, headache,, blood dyscrasias, nystagmus, N/V, constipation, sedation, teratogenic
	Anticonvulsant for partial or generalized, absence seizures	valproic acid	Depakene® Apo-Valproic®	10-15 mg/kg/d PO in divided doses, increase incrementally until therapeutic dose to max of 60 mg/kg/d	Hypersensitivity, hepatic disease, urea cycle disorders	Hepatic failure, headache, somnolence, alopecia, N/V, diarrhea, tremor, diplopia, thrombocytopenia, hypothermia, pancreatitis, encephalopathy, most teratogenic AED (dose-dependent)
	Anticonvulsant for absence seizures	ethosuximide	Zarontin®	500 mg/d PO, increase by 250 mg every 4-7 d to max 1.5 g/d in divided doses	Hypersensitivity (succinimides)	CNS depression, blood dyscrasias, SLE, Stevens-Johnson syndrome, GI symptoms
Stroke Prevention in Atrial Fibrillation	Anticoagulant (direct thrombin inhibitor)	dabigatran	Pradaxa®	110 mg PO BID or 150 mg PO BID	CrCl <30 mL/min, significant hemostatic impairment, or CNS lesions within 6 mo with high-risk of bleeding	Dyspepsia, gastritis, bleeding
	Anticoagulant (Factor Xa inhibitor)	rivaroxaban	Xarelto®	15 mg PO once daily or 20 mg PO once daily	Concomitant anticoagulant, hepatic disease, pregnancy, strong CYP3A4 and P-glycoprotein inhibitors e.g. itraconazole, ritonavir	Bleeding
	Anticoagulant (Factor Xa inhibitor)	apixaban	Eliquis®	2.5 mg PO BID or 5 mg PO BID	Active bleeding, gastrointestinal bleeding, recent cerebral infarction, active peptic ulcer disease with recent bleeding, hepatic disease with coagulopathy	Bleeding (conjunctival, gastrointestinal, gingival, contusion, hematoma, epistaxis, hematuria)
	Anticoagulant (Factor Xa inhibitor)	edoxaban	Savaysa®	30 mg PO or 60 mg PO once daily	Active bleeding, hepatic disease, CrCl <30 mL/min	Bleeding
Mild to Moderate Alzheimer's Disease or Dementia with Lewy Bodies	Cholinesterase Inhibitor	donepezil	Aricept®	5 mg PO once daily, may increase to 10 mg PO once daily after 4-6 wk	Hypersensitivity to donepezil or to piperidine derivatives	Diarrhea, N/V, insomnia, muscle cramps, fatigue, anorexia, HTN, syncope, AV block
Multiple Sclerosis	MS Disease Modifying Therapy	interferon-β-1b interferon-β-1a SC interferon-β-1a IM	Betaseron® Rebif® Avonex®	0.25 mg (8 MU) SC every other day 44 µg SC 3 times/wk 30 µg IM once weekly	Pregnancy, hypersensitivity to natural or recombinant interferon-β	Injection site reactions, injection site necrosis, flu-like symptoms (fever, chills, myalgia; tend to decrease over time)
	MS Disease Modifying Therapy	glatiramer acetate	Copaxone®	20 mg SC once daily	Hypersensitivity to glatiramer or mannitol	Injection site reactions, nausea, transient chest pain, vasodilation
	MS Disease Modifying Therapy	natalizumab	Tysabri®	300 mg IV given over 1 h, every 4 wk	Hypersensitivity to natalizumab, progressive multifocal leukoencephalopathy	Rash, nausea, arthralgia, headache, infections, rare risk of progressive multifocal leukoencephalopathy and melanoma
	MS Disease Modifying Therapy	fingolimod	Gilenya®	0.5 mg PO once daily	Not available	Diarrhea, transaminitis, headache, bradyarrhythmia, lymphopenia
Spasticity (i.e. MS)	Muscle Relaxant – Antispastic	baclofen	Lioresal®	5 mg PO TID, increase by 15 mg/d q3d to max dose 80 mg/d in three divided doses	Hypersensitivity to baclofen	Transient drowsiness, daytime sedation, dizziness, weakness, fatigue, convulsions, constipation, nausea

SJS: Stevens-Johnson Syndrome, TES: toxic epidermal necrolysis

Landmark Neurology Trials

Trial Name	Reference	Clinical Trial Details
Stroke		
NASCET	NEJM 1991;7:445-53	**Title**: Beneficial Effect of Carotid Endarterectomy in Symptomatic Patients with High-Grade Carotid Stenosis **Purpose**: To assess the efficacy of carotid endarterectomy for reducing stroke risk in patients with a recent adverse cerebrovascular event and ipsilateral carotid stenosis. **Methods**: 659 patients with recent (≤120d) hemispheric or retinal TIA or nondisabling stroke with 70-99% stenosis received optimal medical care. Those assigned to surgical treatment underwent carotid endarterectomy. **Results**: Estimated cumulative risk of any ipsilateral stroke at 2yr was 26% in medical patients and 9% in surgical patients (AR reduction, 17%; P<0.001), and 13.1% and 2.5%, respectively, for major or fatal ipsilateral stroke (10.6%; P<0.001). **Conclusion**: Carotid endarterectomy effectively reduces stroke risk in patients with a recent adverse cerebrovascular event and ipsilateral carotid stenosis.
NINDS tPA	NEJM 1995;333:1581-87	**Title**: Tissue Plasminogen Activator for Acute Ischemic Stroke **Purpose**: To investigate the clinical efficacy of IV tPA in acute ischemic stroke. **Methods**: Patients with acute ischemic stroke randomly assigned to receive tPA or placebo. **Results**: At 24h, there was no significant differences in neurologic improvement between tPA and placebo. Clinical benefit of tPA was observed at 3 mo for all outcome measures. Patients treated with rtPA were 30% less likely to be disabled at 3mo. tPA was associated with significantly more symptomatic intracerebral hemorrhage within 36 h after stroke. **Conclusion**: When administered within 3 h of ischemic stroke, tPA improved clinical outcomes despite a greater risk of symptomatic intracerebral hemorrhage.
WASID	NEJM 2005;352:1305-16	**Title**: Comparison of Warfarin and Aspirin for Symptomatic Intracranial Arterial Stenosis **Purpose**: To compare the safety and efficacy of warfarin and aspirin in the treatment of stroke caused by atherosclerotic intracranial arterial stenosis. **Methods**: 569 patients with TIA or stroke caused by 50-99% stenosis were randomized to receive warfarin (target international normalized ratio, 2.0-3.0) or aspirin (1300 mg once daily). **Results**: Study stopped early due to safety concerns. Adverse events included death (4.3% on aspirin vs. 9.7% on warfarin; P=0.02), major hemorrhage (3.2% vs. 8.3%; P=0.01), and MI or sudden death (2.9% vs. 7.3%; P=0.02) during 1.8 yr mean follow-up. **Discussion**: In patients with intracranial arterial stenosis, warfarin afforded no clinical benefit and was associated with more adverse events. Aspirin is thus preferable.
SPARCL	NEJM 2006;355:549-59	**Title**: High-Dose Atorvastatin after Stroke or Transient Ischemic Attack **Purpose**: To investigate whether statins reduce the risk of stroke after a recent stroke or TIA. **Method**: 4731 patients with stroke or TIA within 1-6 mo and LDL=2.6-4.9 mmol/L and without coronary disease were randomly assigned to receive 80 mg atorvastatin daily or placebo. **Results**: Fatal or nonfatal stroke occured in 11.2% of patients receiving atorvastatin and 13.1% receiving placebo (5-yr absolute reduction in risk, 2.2%; adjusted hazard ratio, 0.84; 95% CI, 0.71 to 0.99; P=0.03). The atorvastatin group experienced relatively more hemorrhagic strokes (hazard ratio 1.66 (1.08-2.55)). **Conclusion**: Atorvastatin reduced the overall incidence of strokes in patients with recent stroke or TIA, despite an increase in rates of hemorrhagic stroke
ECASS 3	NEJM 2008;359:1317-29	**Title**: Thrombolysis With Alteplase 3 to 4.5 Hours After Acute Ischemic Stroke **Purpose**: To investigate the efficacy and safety of alteplase administered 3-4.5 h following stroke onset. **Methods**: Randomly assigned 821 patients with acute ischemic stroke to receive IV alteplase (0.9 mg/kg) or placebo. Primary outcome was disability at 90d (favorable outcome: 0-1 on modified Rankin scale) or unfavorable outcome (2-6). **Results**: Alteplase was associated with more favourable outcomes than placebo (52.4% vs. 45.2%; OR, 1.34; 95% CI, 1.02-1.76; P=0.04). Intracranial hemorrhage was more frequent on alteplase vs. placebo (27.0% vs. 17.6%; P=0.001). No significant difference in mortality or adverse events. **Conclusion**: In patients with acute ischemic stroke, IV alteplase administered 3-4.5 h after symptom onset significantly improved clinical outcomes but also increased the frequency of ICH.
RELY	NEJM 2009;361:1139-51	**Title**: Dabigatran Versus Warfarin in Patients with Atrial Fibrillation **Purpose**: To investigate the efficacy and safety of dabigatran vs. warfarin in preventing stroke or systemic embolism in patients with AFib. **Methods**: 18,113 patients with AFib and risk of stroke were randomly assigned to receive dabigatran 110-150 mg BID or adjusted-dose warfarin. **Results**: Rates of stroke or systemic embolism were 1.69%/yr on warfarin and 1.53%/yr on 110 mg dabigatran (relative risk with dabigatran, 0.91; 95% CI, 0.74-1.11) and 1.11%/yr on 150 mg dabigatran (0.66 (0.53-0.82)). Frequency of major bleeding was 3.36%/yr on warfarin and 2.71%/yr on 110 mg of dabigatran (P=0.003) and 3.11%/yr on 150 mg dabigatran (P=0.31). **Conclusion**: When compared to warfarin, dabigatran has potential to lower stroke rates or major hemorrhage depending on dose.
CREST	NEJM 2010;363:11-23	**Title**: Stenting Versus Endarterectomy for Treatment of Carotid-Artery Stenosis **Purpose**: To investigate the efficacy and safety of carotid-artery stenting vs. carotid endarterectomy for treating carotid-artery stenosis. **Methods**: 2502 patients with carotid stenosis were randomly assigned to carotid-artery stenting or carotid endarterectomy. Primary composite outcome was MI, stroke, or death from any cause or any ipsilateral stroke within 4yr. **Results**: Estimated 4-year rates of the primary outcome did not significantly differ between stenting and endarterectomy (7.2% vs. 6.8%; hazard ratio with stenting, 1.11 (0.81-1.5)); P=0.51). Rates of individual endpoint components for stenting vs. endarterectomy were 0.7% vs. 0.3%, P=0.18 for death; 4.1% vs. 2.3%, P=0.01 for stroke; and 1.1% vs. 2.3%, P=0.03 for MI. **Conclusion**: Composite primary outcome risk did not differ significantly between stenting and endarterectomy in patients with carotid stenosis.
ARISTOTLE	NEJM 2011;365:981-92	**Title**: Apixaban Versus Warfarin in Patients With Atrial Fibrillation **Purpose**: To assess the efficacy of apixaban in reducing the risk of stroke as compared to warfarin. **Methods**: 18,201 patients with AFib and one additional risk factor for stroke were randomized to receive either apixaban or warfarin. The primary outcome was stroke or systemic embolism. **Results**: The rate of stroke or systemic embolism was lower in the apixaban group than in the warfarin group (1.27% vs. 1.60%; P<0.001 for noninferiority, P=0.01 for superiority). The rates of major bleeding (2.13% vs. 3.09%; P<0.001) and death (3.52% vs. 3.94%; P=0.047) were lower in the apixaban group than in the warfarin group. **Conclusion**: In patients with AFib, apixaban was superior to warfarin for preventing stroke or systemic embolism with lower rates of major bleeding and death.
AVERROES	NEJM 2011;364:806-17	**Title**: Apixaban in Patients with Atrial Fibrillation **Purpose**: To investigate the efficacy and safety of apixaban in preventing stroke in patients with AFib. **Methods**: 5599 patients with AFib at increased risk for stroke and who were unsuitable for vitamin K antagonist therapy were randomly assigned to receive 5 mg apixaban BID or aspirin (81-324 mg daily). **Results**: Study terminated early due to clear apixaban benefit. Rates of stroke or systemic embolism were 1.6%/yr on apixaban and 3.7%/yr on aspirin (hazard ratio with apixaban, 0.45 (0.32 to 0.62); P<0.001). There were no significant differences in rates of major bleeding or intracranial bleeding. **Conclusion**: Apixaban reduced the risk of stroke or systemic embolism without increasing bleeding or hemorrhage risk in patients with AFib unsuitable for vitamin K antagonists.
ROCKET AF	NEJM 2011;365:883-91	**Title**: Rivaroxaban Versus Warfarin in Nonvalvular Atrial Fibrillation **Purpose**: To investigate if rivaroxaban is noninferior to warfarin in preventing stroke or systemic embolism in AFib. **Methods**: 14264 patients with nonvalvular AFib at increased risk for stroke were randomly assigned to receive either rivaroxaban (20 mg once daily) or dose-adjusted warfarin. **Results**: Rates of stroke or systemic embolism were 1.7%/yr on rivaroxaban and 2.2%/yr on warfarin (hazard ratio, 0.79 (0.66 to 0.96); P<0.001 for noninferiority). Significant reductions in ICH (0.5% vs. 0.7%, P=0.02) and fatal bleeding (0.2% vs. 0.5%, P=0.003) were seen in the rivaroxaban group. **Conclusion**: Rivaroxaban was noninferior to warfarin in patients with AFib for preventing stroke or systemic embolism with lower risks of ICH and fatal bleeding.
SAMMPRIS	NEJM 2011;365:993-1003	**Title**: Stenting Versus Aggressive Medical Therapy for Intracranial Arterial Stenosis **Purpose**: To compare the efficacy of percutaneous transluminal angioplasty and stenting (PTAS) vs. medical management in intracranial arterial stenosis. **Methods**: 451 patients with recent TIA or stroke attributed to 70-99% stenosis were randomly assigned to aggressive medical management plus PTAS or aggressive medical management alone. **Results**: 30 d stroke or death rate was 14.7% and 5.8% in the PTAS and medical-management group, respectively (P=0.002). 1-yr rates of the primary end point (stroke or death within 30 d or after a revascularization during follow-up or stroke in the territory of the qualifying artery beyond 30d) were 20.0% in PTAS and 12.2% in medical-management (P=0.009). **Conclusion**: Aggressive medical management in patients with intracranial arterial stenosis was superior to PTAS.

Trial Name	Reference	Clinical Trial Details
INTERACT2	NEJM 2013;368:2355-65	**Title**: Rapid Blood-Pressure Lowering in Patients with Acute Intracerebral Hemorrhage **Purpose**: To investigate the efficacy of rapid lowering of elevated BP for improving outcomes in patients with intracerebral hemorrhage. **Methods**: 2839 patients with spontaneous intracerebral hemorrhage and elevated sBP were randomly assigned to receive intensive treatment (target sBP <140 mmHg within 1 hr) or guideline-based treatment (target sBP <180 mm Hg Hg). **Results**: 52.0% receiving intensive treatment vs. 55.6% receiving guideline-based treatment experienced a primary outcome event (death or major disability) (OR, 0.87 (0.75-1.01); P=0.06). Intensive treatment was associated with significantly lower modified Rankin scores (OR for greater disability, 0.87 (0.77-1.00); P=0.04). **Conclusion**: Intensive BP lowering in intracerebral hemorrhage did not significantly reduce rates of death or severe disability but may improve functional outcomes.
ESCAPE	NEJM 2015;3721019-30	**Title**: Randomized Assessment of Rapid Endovascular Treatment of Ischemic Stroke **Purpose**: To investigate rapid endovascular treatment plus standard care in acute ischemic stroke with a proximal intracranial arterial occlusion, small infarct core, and moderate-good collateral circulation. **Methods**: 316 patients randomly assigned to receive endovascular treatment with the use of available thrombectomy devices plus standard of care (intervention group) or standard care alone (control group). **Results**: The intervention reduced mortality (10.4%, vs. 19.0% in controls; P=0.04) and was associated with improved scores on the modified Rankin scale at 90 d (common OR, 2.6; 95% CI, 1.7 to 3.8; P<0.001). **Conclusion**: Rapid endovascular treatment improved functional outcomes and reduced mortality in select patients with acute ischemic stroke.
MR CLEAN	NEJM 2015;372:11-20	**Title**: A Randomized Trial of Intraarterial Treatment for Acute Ischemic Stroke **Purpose**: To investigate functional outcomes of intraarterial treatment for emergency revascularization in patients with acute ischemic stroke caused by a proximal intracranial arterial occlusion. **Methods**: 500 patients that could be treated intraarterially within 6h after symptom onset were randomly assigned to either intraarterial treatment plus standard care or standard care alone. **Results**: The rate of functional independence (modified Rankin score, 0 to 2) was higher in the intervention group (32.6% vs. 19.1%; absolute difference, 13.5%, 95% CI, 5.9 to 21.2). Rates of mortality or symptomatic intracerebral hemorrhage were not significantly different between groups. **Conclusion**: Intraarterial treatment within 6 h following stroke onset was safe and effective in acute ischemic stroke caused by intracranial, proximal arterial occlusion of the anterior circulation.
DAWN	NEJM 2018;378:11-21	**Title**: Thrombectomy 6 to 24 Hours after Stroke with a Mismatch between Deficit and Infarct **Purpose**: To investigate the efficacy and safety of endovascular thrombectomy performed >6 h following ischemic stroke onset. **Methods**: 206 patients with acute stroke who were well 6-24 h earlier with mismatch between clinical deficit and infarct were randomly assigned to thrombectomy plus standard care or standard care alone (control). **Results**: At 90 d, mean scores on a modified Rankin scale were 5.5 in thrombectomy and 3.4 in controls (adjusted difference, 2.0 points (1.1-3.0); posterior probability of superiority, >0.999), and the rate of functional independence were 49% and 13%, respectively (adjusted difference, 33% (24-44); posterior probability of superiority, >0.999). **Conclusion**: Adding thrombectomy to standard of care improved disability outcomes in patients with acute stroke who were well 6-24 h earlier with clinical deficit and infarct mismatch.
POINT	NEJM 18;379:215-25	**Title**: Clopidogrel and Aspirin in Acute Ischemic Stroke and High-Risk TIA **Purpose**: To investigate the efficacy of clopidogrel plus aspirin to reduce the rate of stroke recurrence during the first 3 mo following a minor ischemic stroke or TIA. **Methods**: 4881 patients with minor ischemic stroke or high-risk TIA were randomly assigned to clopidogrel plus aspirin or aspirin plus placebo. **Results**: Fewer major ischemic events were observed in those receiving clopidogrel plus aspirin (5%) vs. aspirin plus placebo (6.5%) (hazard ratio, 0.75 (0.59-0.95); P=0.02). Risk of major hemorrhage was greater in those receiving clopidogrel plus aspirin (0.9%) vs. those receiving aspirin plus placebo (0.4%) (2.32 (1.10-4.87); P=0.02). **Conclusion**: Clopidogrel plus aspirin lowers risk of major ischemic events but increases risk of major hemorrhage in patients with minor ischemic stroke or high-risk TIA.
Multiple Sclerosis		
Interferon-β-1b is effective in relapsing-remitting multiple sclerosis. I. Clinical **results** of a multicenter, randomized, double-blind, placebo-controlled trial. The IFNB Multiple Sclerosis Study Group. 1993	Neurology 1993;43:655-61	**Title**: Interferon-β-1b is effective in relapsing-remitting multiple sclerosis. I. Clinical results of a multicentre, randomized, double-blind, placebo-controlled trial. The IFNB Multiple Sclerosis Study Group **Purpose**: To investigate the efficacy of Interferon-β-1b (IFNB) in relapsing-remitting MS. **Methods**: 372 ambulatory patients with relapsing-remitting MS self-administered either placebo, 1.6 million international units (MIU) of IFNB, or 8 MIU of IFNB. **Results**: After 2 yr, rates of annual clinical exacerbation for patients on placebo were 1.27; 1.17 for 1.6 MIU IFNB; and 0.84 for 8 MIU IFNB, indicating both treatment groups performed significantly better than placebo. In the 8 MIU group, there was a twofold reduction in the frequency of moderate-severe attacks. **Conclusion**: Interferon-β-1b reduces relapse rate and severity of relapses in relapsing-remitting MS.
PreCISe	Lancet 2009;374:1503-11	**Title**: Effect of Glatiramer Acetate on Conversion to Clinically Definite Multiple Sclerosis in Patients with Clinically Isolated Syndrome (Precise Study): A Randomised, Double-Blind, Placebo-Controlled Trial **Purpose**: To assess the efficacy of early treatment with glatiramer acetate in delaying onset of clinically definite MS. **Methods**: 481 patients with clinically isolated syndrome with unifocal manifestation, and ≥2 T2-weighted brain lesions >6 mm, received SC glatiramer acetate (20 mg/d) or placebo for up to 36 mo. **Results**: Relative to placebo, the risk of developing clinically definite MS was reduced by 45% with glatiramer acetate (hazard ratio 0.55, 95% CI 0.40-0.77; P=0.0005). It prolonged the time for 25% of patients to convert to clinically definite disease by 115%. Injection-site reactions and immediate post-injection reactions were the most common adverse events. **Conclusion**: In patients presenting with clinically isolated syndrome and brain lesions, conversion to clinically definite MS can be delayed by early treatment with glatiramer acetate.
Seizure Disorders and Epilepsy		
MESS	Lancet 2005;365:2007-13	**Title**: Immediate Versus Deferred Antiepileptic Drug Treatment for Early Epilepsy and Single Seizures: A Randomised Controlled Trial **Purpose**: To investigate the relative benefits and risks of initiating or withholding antiepileptic drug treatment in patients with few or infrequent seizures. **Methods**: 1443 patients with single seizures or early epilepsy were randomly assigned to receive either immediate or deferred antiepileptic drug treatment. **Results**: Immediate treatment prolonged time to 1st seizure (hazard ratio 1.4; (95% CI 1.2-1.7)), 2nd seizure (1.3 (1.1-1.6)), and first tonic-clonic seizure (1.5 (1.2-1.8)). Time to 2-yr remission of seizures was reduced by immediate treatment (P=0.023). The proportion of patients that were seizure-free between years 3-5 were 76% on immediate treatment and 77% on deferred treatment. **Conclusion**: In individuals with single or infrequent seizures, seizure occurrence in the first 1-2 yr is reduced by immediate antiepileptic drug treatment, but long-term remission is not affected.
SANAD	Lancet 2007;369:1016-26	**Title**: The SANAD Study of Effectiveness of Valproate, Lamotrigine, or Topiramate for Generalised and Unclassifiable Epilepsy: An Unblinded Randomised Controlled Trial **Purpose**: To investigate the long-term effects of valproate, lamotrigine, and topiramate in patients with generalized onset seizures or seizures that are not easily classified. **Methods**: Between 1999-2004 during the initial trial, patients were randomly assigned to receive valproate, lamotrigine, or topiramate, and follow-up data were obtained up to 2006. **Results**: Valproate was significantly better than topiramate for time to treatment failure (hazard ratio 1.57 (95% CI 1.19-2.08)), and significantly better than lamotrigine for time to 12-mo remission (0.76 (0.62-0.94)). **Conclusion**: Valproate should remain the first line therapy for generalised and unclassified epilepsies due to superior efficacy and safety profiles.

Trial Name	Reference	Clinical Trial Details
Alzheimer's Disorder		
CATIE-AD	Am J Psychiatry 2011;168:831-839	**Title:** Cognitive Effects of Atypical Antipsychotic Medications in Patients with Alzheimer's Disease: Outcomes from CATIE-AD **Purpose:** To examine the effects of time and treatment on neuropsychological functioning during the Clinical Antipsychotic Trials of the Intervention Effectiveness-Alzheimer's Disease study. **Methods:** 421 outpatients with Alzheimer's disease and psychosis or agitated/aggressive behaviour were randomized to receive olanzapine, quetiapine, risperidone, or placebo in a multicentre double-blinded RCT. MMSE and Alzheimer's Disease Assessment Scale (ADAS) scores were measured at 36 wk. **Results:** Patients receiving atypical antipsychotics exhibited a faster rate of cognitive decline as measured by MMSE scores (– 0.067/wk vs. -0.007/ wk). They also had a significantly faster decline compared to placebo on a composite measure of ADAS, MMSE, and various other cognitive tests (-0.011/wk vs. -0.001/wk). **Conclusions:** Long-term use of atypical antipsychotics for behavioural symptoms and psychosis in dementia patients is associated with greater rates of cognitive decline.
Neuropathic Pain		
A Vaccine to Prevent Herpes Zoster and Postherpetic Neuralgia in Older Adults. Oxman et al. 2005	NEJM 2005;352:2271-84	**Title:** A Vaccine to Prevent Herpes Zoster and Postherpetic Neuralgia in Older Adults **Purpose:** To investigate whether vaccination against herpes zoster would decrease the incidence and/or severity of infection or postherpetic neuralgia in older adults. **Methods:** 38546 adults aged ≥60 yr were randomized to receive live attenuated Oka/Merck VZV vaccine (zoster vaccine) or placebo. **Results:** Vaccination reduced herpes zoster illness burden by 61.1% (P<0.001), incidence of infection by 51.3% (P<0.001), and incidence of PHN by 66.5% (P<0.001). **Conclusion:** Among older adults, the zoster vaccine significantly reduced morbidity from herpes zoster and postherpetic neuralgia.
